PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

An emergency meeting of the Council was held on September 1, 1922, at 35, Russell Square, to consider principally the final arrangements for the congress and exhibition.

There was present: Messrs. Marcus Adams, Angus Basil, Arthur Bennett, Frank Brown, W. B. Chaplin, Gordon Chase, Alexander Corbett, C. F. Dickinson, W. E. Gray, Reginald Haines, George Hana, William Illingworth, Herbert Lambert, R. N. Speaight, Lang Sims, H. C. Spink, F. G. Wakefield, and W. H. O. Wedlake, with Mr. Alfred Ellis (secretary), and Mr. Jenkyn Griffiths (editor).

Mr. Alexander Corbett took the chair.

Apologies for absence were read from Mr. Swan Watson (president), Mr. Chapman, and Mr. Chidley.

The council considered, in committee, the final arrangements for the congress and exhibition.

The secretary, asking for voluntary help, Mr. Frank Brown and Mr. Wedlake undertook to collect the tickets at the various stages of the Windsor excursion, Mr. Haines and Mr. Chase to collect the tickets at each of the other outings, Mr. Bennett to collect the tickets on the occasion of the Tuesday luncheon, Mr. Lang Sims to be at the door on the occasion of the lectures and other meetings to see that these were restricted to members of the congress, and Mr. Haines to act as master of the ceremonies at the president's reception.

Mr. Haines reported that a number of London studios would be available for visits on the Wednesday morning, but that arrangements as to some of them were not yet completed. It was suggested that in addition to those already approached, Mr. Oscar Hardee and Mr. Banfield might allow their studios to be visited, and Mr. Haines undertook to try and secure the necessary permissions. Mr. Sims reported that the studios of the Amalgamated Press would take seventy-five visitors.

With regard to the assistants' evening, Mr. Chase reported on the number of applications so far received for tickets, and it was agreed that if any assistants came who had not the proper tickets, Mr. Sims, who would be at the door, should use his discretion as to admittance.

It was stated that Mr. Charles Aylett and Mr. J. Kennedy, of Toronto, and Mr. Pirie Macdonald, of New York, had already arrived; also that M. Pasquad, editor of *Photo-Paris*, intended to be present.

Mr. Lambert gave details of the musical programme. He proposed to engage the services of a trio of instrumentalists throughout the week, and to have each session opened with a little music. The

musicians would be engaged in the exhibition room when not actually in the congress room.

It was decided to ask the president of the Royal Photographic Society to take the chair on the Tuesday evening, Mr. Corbett, on the Wednesday afternoon, and Colonel Moore-Brabazon, M.P., on the Wednesday evening. Other subjects for brief discussions on the Wednesday afternoon, in addition to the one announced, were called for, and Mr. Haines agreed to ask Mr. Drummond Young to open a discussion on some subject of interest; Mr. Frank Brown undertook to open one on "Photographic Parasites," and Mr. Wakefield, one on "The Enlargement Question"; while it was suggested that "Co-operative Advertising" might also be discussed. It was agreed that openers be limited to ten minutes.

The Council then went out of committee, and Mr. Illingworth formally proposed, and Mr. Brown seconded, that all the arrangements involving any expenditure which had been agreed to at that meeting by the Council sitting as a committee should be approved. This was agreed to unanimously.

Mr. Hana asked for some suggestions from the Council as to the line he should take in his address on "Assistants as Associate Members." Several members of Council gave their opinions, but the general sense of the discussion was that Mr. Hana should speak as an individual member without compromising the Council.

The Exhibition.

Mr. Speaight reported that the exhibits had come in most satisfactorily; the exhibition would be larger and more representative than it had been before. It was altogether a magnificent show. Mr. Basil had taken over the work in connection with the English section, and Mr. Adams was looking after the Continental section. The Selection Committee—which was distinct from the judges who awarded the actual medals—consisted of Mr. Bertram Park, Mr. Banfield, Mr. Lambert, Mr. Basil, Mr. Wakefield, and Mr. Corbett, and Mr. Herbert Vandyke was also to be asked to serve.

Mr. Wakefield raised the question of the insurance of the exhibits, and on the motion of the Chairman, seconded by Mr. Basil, Mr. Wakefield agreed to approach the Fine Art Insurance Company with a view to the insurance of the picture exhibits, and to ask the same firm to negotiate with the stall-holders as to the insurance of their exhibits.

Mr. Haines reported that the cost of the catalogue was well covered, and that each stall-holder, as well as the General Electric Company, would be allowed a special advertisement. The question of complimentary copies was left to Mr. Haines's discretion.

New Members, Deaths, and Resignations.

The following new members were admitted:—Miss K. L. West (Rochester), J. Dixon Scott (Holborn), E. Lucker (Bournemouth), E. Milner (North Finchley), W. A. Sivyer (Greenwich), E. J. Edwards (in place of R. H. Hudson, retiring, of the same firm), E. O. Reynolds (Strond), G. Hughes (Histed, Baker Street), E. Millar (Sloane Street), E. Bradshaw (Padiham), also Lydell Sawyer (Sloane Street) rejoining.

The death was reported of Mr. Blunt Turner, partner of Mr. F. Read, Stockport, and the resignations of Bapuji Gehangi, of Bombay, and G. W. Lawrie, of Lucknow.

The Secretary asked for instructions as to the admission of members during Congress week, and it was agreed that he should have the power to accept nominations, and that if in any doubt he should consult Chairman of Council or Treasurer.

"Record" Committee.

The Chairman reported on the meeting of the Committee appointed at the last meeting to discuss the management of the "Record." The Committee had met and had agreed to recommend to the Council that the Editor should have entire control of the "Record," and should be assisted by an advisory committee, which, for the two next issues, would meet twice a month, the Committee to consist of Messrs. Adams, Hana, Wakefield, and the Secretary. Mr. Speaight had kindly agreed to act as honorary treasurer of the "Record" finances for six months, and had also accepted the duty of collecting the accounts and of placing the financing of the "Record" in proper working order, such as would be approved by the accountant of the Association. Mr. Illingworth proposed, and Mr. Frank Brown seconded, that the report with the recommendation be adopted, and that the Committee, as stated, be appointed, to be called the Publications Committee; further, that any expense incurred by Mr. Speaight in the shape of allowances to his secretary for getting the accounts in order should be met out of the "Record" funds. This was agreed to unanimously, and Mr. Speaight was thanked for his offer. The Propaganda Committee was thereby dissolved.

The British Empire Exhibition, 1924.

The Secretary read a letter he had received from the Secretary of the British Empire Exhibition in reply to his own letter as instructed at the last meeting, stating that after due consideration of a large number of applications, the concession of photographic rights had been granted to Messrs. Campbell Gray, Ltd., who, in addition to being contributors to the guarantee fund, offered the most favourable terms.

Mr. Wakefield stated that he had had an order from one firm for photography in connection with the exhibition. The firm was one for which he had been accustomed to do photography for many years. On making the usual preparations for executing the order he was told that permission must be sought from Messrs. Campbell Gray, and when he asked this firm for permission he was told that Messrs. Campbell Gray themselves would do the work for two guineas, or that they would require two guineas if the work was done by someone else. This was a prohibitory tax, because the order itself was not more than a two-guinea one.

After some further discussion, it was decided that information as to the exact terms of the contract should be procured, and that the matter should be brought forward again for discussion after the Congress.

The Edinburgh Society of Professional Photographers.

The Secretary read letters which he had received from the President and Secretary of the Edinburgh Society of Professional Photographers, arising out of some recent discussion as to whether the Edinburgh Society was affiliated with the Association. Both letters conveyed very friendly feelings and a desire for co-operation, and the President wrote assuring the Association that there was no unfriendliness; the object of drawing attention to the matter at the meeting in Edinburgh was simply to correct a technical error. The interests of the two bodies were in common.

The Chairman said that this was a very satisfactory explanation of what seemed, in print, a very terse statement.

Nominations for the Council.

Mr. Sims proposed, and Mr. Chase seconded, that Mr. Futcher, of Southsea, who had expressed his willingness to be a member of Council, be nominated for the Council. It was stated that a ballot would entail only a very slight expense and trouble. The nomination was agreed to.

This concluded the business, which had occupied four hours.

Commercial & Legal Intelligence.

NEW COMPANIES.

Precision Photo Printing Plant, Ltd.—This private company was registered on August 23, with a capital of £10,000, in £1 shares. Objects: To acquire from S. H. Morse his interest in a certain patent, and to carry on the business as indicated by the title and that of engineers, etc. The first directors are: E. W. Smith, Eastwood, Worcester Park, Surrey (chairman); S. H. Morse, Clarendon Hotel, Watford. The last named is permanent. Qualification: £1. Remuneration at the rate of £50 each per annum. Registered office: 120, Moorgate Street, E.C.

Christie & Hodgson, Ltd.—This private company was registered on August 29, with a capital of £2,000 in £1 shares. Objects: To take over the business of manufacturers of and dealers in photographic, optical, lantern, electrical and wireless apparatus, and cabinet and general woodworkers, etc., carried on by James Christie & Sons, Ltd., at 246, West Street, Sheffield, and generally all or any of the assets of the retail business of the said company. The first directors are: J. Christie, 222, Ecclesall Road, Sheffield (managing director and chairman); G. Christie, 26, Edgebrook Road, Sheffield (both directors of James Christie & Sons, Ltd); E. O. Hodgson, 57, Wake Road, Sheffield. Qualification: 1 share. Secretary: J. Christie. Registered office, 246, West Street, Sheffield.

News and Notes.

"The Club Photographer" for September is a Keighley Number. It contains pictures and useful articles by A. S. Dean, E. Horner, H. R. Wade, W. Speight, and other members of the Keighley and District Photographic Association.

The R.P.S. Exhibition will this year have the distinction of being formally opened by Mr. Solomon J. Solomon, R.A., president of the Royal Society of British Artists. The function will take place at 35, Russell Square, on Saturday, September 16.

Mr. A. Dordan Pyke asks us to note that his address is now :—Oulton, Meadway, Epsom, to which letters should be sent dealing with his numerous engagements as a lecturer before photographic societies on the goods of a number of leading photographic firms.

Photographers get the best advertising in the world, according to A. A. Chilcote, of Cleveland, who says :—"People don't buy a dozen pictures to look at themselves. They buy them to give away and indirectly advertise you. People gladly pay a dollar more a pound for candy when it is done up in a pretty box; you can apply the same principle to photographs."

Wold Air Brushes.—We have received the catalogue of the air brushes made by the Wold Air Brush Manufacturing Co., 2173, North California Avenue, Chicago, a firm which manufactures a large number of types of air brush for photographic and other purposes, together with accessory apparatus, such as air-compressing equipment, and a large selection of the necessary colours.

Parcel Post to India.—The Postmaster-General announces that henceforth parcels for India should not bear adhesive customs declarations, but must be accompanied by despatch notes and non-adhesive customs declarations, like parcels for foreign countries. One despatch note and customs declaration may be used for not more than three parcels from the same sender for the same addressee.

MM. E. Krauss, 18-20, Rue de Naples, Paris, have just issued a 64-page catalogue of the photographic lenses and other optical apparatus manufactured by them. They are makers under licence of the various models of Zeiss lens, and also of a considerable variety of cameras, including several stereoscopic instruments, a folding focal-plane and the very ingenious "Photo-Revolver," taking 48 plates measuring 22 by 36 mm. The list is obtainable by those of our readers who are interested on application to the firm in Paris.

Photographs of Salesmen are used in an American store to aid customers in identifying them. The Philadelphian "Bulletin of Photography" says that in the furniture department of a large store in Pittsburg is a bulletin board on which are posted the photographs of the salesmen in the department with their names under them. The department has found that "lookers" often return determined to buy. They prefer to be waited on by the salesmen who showed them articles on their previous visit to the department, but almost invariably have forgotten to ask their names. So, except for the photographs, they would have no way of finding the salesmen unless they happened to see them in the department.

Plaster Casts.—From time to time we have referred those requiring a classical cast for use in the study of studio lighting to the firm of D. Brucciani & Co. We now learn that the business of this firm has been transferred to the Board of Education and removed from Goswell Road to the Victoria and Albert Museum, South Kensington, London, S.W.7, where it is under the direction of Mr. Paul Ryan. A catalogue has been issued very fully illustrating the casts of many statues, busts and other examples of classical sculpture, which are supplied at relatively moderate prices. For example, that of the Venus de Capua, No. 2265, is sold for about 18s., whilst that of another suitable as a still-life model, namely, The Boy, by Luca della Robbia, costs about 13s. Packing and carriage are extra to the prices in the catalogue.

The Antiquity of the "Tintype."—The "tintype" or "while-you-wait" photograph is in principle no new thing, says a writer in the "Bazaar." The modern examples, however, are produced by the "dry" method, whereas the older forms were by the "wet" method. The latter necessitated a dark-room (once a familiar object of the seashore, and not even now quite disappeared), because of the tin "plate" having to be prepared immediately before use. This old process was first "thought out" in 1853 by an American, who had to send photographs—then commonly made upon glass—by post. The process was first worked commercially in 1855 by another American—J. W. Griswold—who named his results "Melainotypes," but this was soon changed to "Ferrographs," and there were frequent references to the latter in the English photographic Press during 1856. This style of portraiture enoyed a tremendous boom about 1880, but it gradually died down, only to be revived when the "dry" process came along with the compact "cannon," "button," and other types of easily-manipulated cameras, as are now commonly used.

Congress Finals.—Members of the P.P.A. who are attending next week's "coming of age" congress, are asked particularly to note the following items respecting the conditions of attendance :—Members who have not obtained their congress membership card will be admitted to the annual general meeting on presenting the notice convening the meeting at the entrance to the Prince's Galleries, Piccadilly, W.1.

It is imperative that members should bring their congress membership cards with them, as these must be shown on all occasions (with the exception of the annual general meeting) in order to obtain free admission.

Members who have not paid their subscription for 1922-23 and are not in possession of their membership card, are not entitled to vote at the annual general meeting, or to have free admission to congress lectures or excursions. Each member may bring a professional friend to the congress by obtaining a special card (price 5s.) from the secretary, Mr. Alfred Ellis. This card confers the privileges of membership during the congress week.

Special attention is asked to the fact that only 130 persons can take part in the congress dinner, and that, therefore, early application for tickets should be made. The dinner will be held at the Prince's Galleries on Friday evening, September 15, at 7 o'clock.

Prevention of Art Forgeries. — Art connoisseurs have been much disturbed recently about the number of clever imitations of famous masters which have found their way into sale-rooms, and none of the suggestions so far made for preventing forgery promises to be really effective. One of the best, which, if carried out, would put an end to forgeries so far as present and future masters are concerned, is made by M. José Théry, a barrister of the Court of Appeal. Briefly (says the "Daily Telegraph") his proposal is that a register of pictures should be established which would identify them from the day of their completion. An artist of note on finishing a work would notify the fact to the official registry of pictures, giving full details of his picture and two photographs, one of the work as a whole, and the other of a very small part of it, so enlarged as to show the smallest detail of the brush marks and texture. Each sale of the picture which followed would be recorded in the register, so that a purchaser on buying a well-known work could obtain with it a document almost corresponding to the certificates issued concerning animals registered in stud books. The chief flaw in the scheme appears to be that it is often the works of artists little known in their time which in later years are recognised as masterpieces. It is just these which would not have been registered by their modest creators.

Record and Survey of Sussex.—The Photographic Record and Survey of Sussex is continuing its useful work of preserving for future generations pictorial records of objects of interest in the county. Photographs of the removal of the statue of George IV. from the Old Steine site at Brighton are among recent additions. At the annual meeting, held last week at the Brighton Public Library, Mr. J. S. North appealed to people interested in photography to send copies of their photographs. There were thousands of photographers in the county, he said, who had never sent a print. Probably they thought them not worth sending, but in course of time the photographs would become very valuable. What was wanted were photographs of any building likely to be destroyed, the entrances to towns and villages, etc. What would they not give for a view of the entrance to Brighton 50 years ago? Mr. Law moved the adoption of the report, which stated that in consequence of the cost of photographic materials, only a few additions had been made recently to the collection at the Public Library, Brighton; but as the price was now lower the Council had decided to add a number of photographs of interest during the next few months. There were some 3,000 prints and sketches, also 500 lantern slides for lecture use in the collection. The officers were re-elected en bloc. Mr. Frederick Harrison (Hon. Secretary) drew attention to a circular sent out by the Sussex Archæological Society with reference to the formation of a collection of photographs. This he thought was duplicating the work of the Photographic Record

to which the Archæological Society transferred that branch of its activities some years ago. It was decided to communicate with the Council of the Society on the subject. Mr. Harrison mentioned that there was a possibility of acquiring the collection of negatives made by the late Rev. Walter Marshall.

GEORGE EASTMAN'S £1,000,000 CINEMA.—A "Daily Telegraph" special article describing the use made of moving pictures by American Universities says: The great new model theatre which Mr. George Eastman has built at a cost of more than £1,000,000, and presented to the University of Rochester, New York, possesses, it is said, nearly a score of organs, including one instrument of unusually large dimensions, equipped with every kind of accessory the ingenuity of the builders could invent. Far more significant than the size of the organ, however, is the fact that, by accepting Mr. Eastman's gift, and consenting to operate the theatre on its own account, one of the leading universities in the United States sets the seal of official approval and recognition on the screen as a great educational force. Not only is it intended to develop the moving picture on scientific lines, but also to train musical students how best to interpret what they see on the screen in terms of music. The theatre, which is fitted up with every device skill can contrive for the comfort and convenience of the 3,400 audience for whom seats are provided, will, it is hoped, serve as a model for the owners of commercially run cinema theatres all over the United States. The novel lighting and ventilating arrangements, as well as whatever improvements in other directions are subsequently developed, are to be placed fully and freely at the disposal of any picture exhibitor who cares to copy and adopt them. Although Rochester is the first university in the States to possess a theatre of its own, ten other American universities, including Yale and Chicago, are already actively engaged in the production of films, and a score of normal schools, colleges, and universities have regular courses in visual instruction. The University of Nebraska has erected a moving-picture studio, and at least four others, including Columbia and New York, are conducting careful scientific investigations into the value of the film as a means of education. Thirty-four cities in the States are now using educational films in their schools. There is thus rapidly coming into being in America a vast mass of enlightened opinion which accepts films as a matter of course, forming a striking contrast to the attitude of official apathy and veiled distrust still too prevalent in this country.

PHOTOGRAPHS FOR BLOCK-MAKING.

To the Editors.

Gentlemen,—While pleading justification in regard to the charge of cynicism in the quotation made by E. H. A., from my article, I must most emphatically enter a plea of "not guilty" to the charge of untruth. I would prefer to define a cynical remark as an "obviously sarcastic exaggeration." Certainly I did not say, or even wish to suggest, that blockmakers actively encourage bad photography in order to keep their art departments going.

No one, however, will surely deny that when photographs sent for blocks are unsatisfactory the possibility of artist's work to make a good result is earnestly recommended. This, of course, is only one of the many factors that have made good photographs requiring no retouching, the exception rather than the rule.

E. H. A. only says that he *believes* my statement to be untrue. He also calls it an aspersion, which, I hope, it is now clear my statement was not intended to be. E. H. A. makes a further suggestion that the retouching is not profitable to the blockmaker. I will not attempt to dispute this point beyond remarking that it looks like asking for more cynicism! As regards his belief, I have always had a strong predilection for facts over mere beliefs that has often got me into hot water. Here goes, however, for another dive.

Fact No. 1.—For many years I have made photographs for blockmaking, either for engravers or printers or for their clients.

Fact No. 2.—A photograph that needs no retouching involves (over an "ordinary" one) a varying amount of trouble=time=money.

Fact No. 3.—Incidentally it requires also a deal of cerebral exertion. That form of labour, however, appears to be considered of little tangible value.

Fact No. 4.—The extra trouble=time=money involved in the "best possible" photograph is far less usually than the cost and time of retouching.

Fact No. 5.—It is extraordinarily difficult to make people see this.

Fact No. 6.—Even when they see it, people often prefer to carry on as usual. For these reasons one can seldom made a "best possible" photograph.

Fact No. 7.—Having been very early and thoroughly inoculated with the theory of the comparative apprentices, I have spent nearly a quarter of a century and much money in trying to acquire the ability to make "best possible" photographs. In my earlier journeyman days the effort frequently involved the sacrifice of ordinary human needs (both inner and outer) to the object in view.

Fact No. 8.—Some people who are acquainted with my work think that those efforts have been worth while.

Fact No. 9.—When they learn the amount of the remuneration weekly that such work commands (?) they usually reverse that opinion.

Still, everybody knows I am always pleased to assist anyone in technical doubt or difficulty to the best of my power. E. H. A.'s friend could have saved his hundred pounds. I should have been glad to guarantee him success for a fifth of that.

If my desire to advance the production of better photography has made me cynical, in face of the craze for cheapness and rush, let me assure E. H. A. there is not an atom of ill-feeling about it.—Yours faithfully,

D. CHARLES.

50, Webb's Road, S.W.11.
September 2.

THE R.P.S. JOURNAL.

To the Editors.

Gentlemen,—In your issue of August 25 Dr. S. E. Sheppard says that a paper of his sent to the R.P.S. "Journal" was rejected. That is, of course, a question that concerns the Journal Advisory Committee, who doubtless had reason for their decision. But when Dr. Sheppard adds parenthetically that the article was abridged "because the 'Journal' does not publish lengthy papers," I feel that the statement should not pass without comment.

Of course, the term "lengthy" is not particularly definite, and I have no idea what number of words it connotes in Dr. Sheppard's mind. Speaking roughly, the "Journal" averages just over 40 pages available for ordinary letterpress, and a "solid" page contains about 800 words. It is no unusual thing for an article to run to a dozen pages, say, 10,000 words, and I should consider this fairly lengthy for such a small magazine. Only in July Dr. Sheppard had a paper which, with diagrams, ran to 14 pages, just one-third of the usual entire space available. In face of such facts I consider Dr. Sheppard's statement misleading, and calculated to give a wrong impression to other contributors.—Yours faithfully,

South Woodford, E.18. W. L. F. WASTELL.
August 31, 1922.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5 cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

B. D.—A gas printing box can be constructed on the lines which Bartholomew & Co., 40, Gerrard Street, London, W.1.

B. D.—A gas printing box can be constructed on the lines which you have indicated, but we should recommend you to purchase one ready made, as it is not easy to make the metal part re-

quired for the light. Messrs. Butcher issue a very good one, the "Klimax," at a reasonable price.

R. R.—You may safely use the ordinary quality of methylated spirit for print cleaning. We have not found any disadvantage from the presence of the small proportion of mineral spirit, while the violet dye tends to correct any green tinge on the lights, if, indeed, it has any effect at all.

J. M.—Although Poland has a somewhat extreme climate, cold in the winter and hot in the summer, it is not worse in this respect than many parts of Europe in which the ordinary plates and papers of the leading makers are regularly and satisfactorily used. We do not think it is possible to recommend one make in preference to another.

M. M.—A certain amount of gold is transferred to the fixing bath, and there continues the toning action. You should pass prints from the toning bath into a weak solution of sulphite of soda, say, 100 grs. of soda sulphite in 20 ozs. of water. This stops the toning action, and if prints are then washed, as they should be, in four or five changes of water before fixing, no further toning action will take place in the fixing bath.

R. L.—By skilful enlargement by highly diffused light, it is just about possible from the very best cinema negatives to make presentable whole-plate enlargements, but in most cases the grain of the film negative becomes very pronounced in the enlargement, unless a good deal of labour is spent in making an enlarged negative and retouching it. We think it is quite necessary practice to make separate still negatives if really good photographs are required.

T. T. A.—Carbon and semi-matt surface prints on developing paper will occasionally show spots of a different texture from the remainder, due to a little surface water collecting at that point during the drying of the print. While some workers have stated that there is no remedy for these, it is found that immersing the prints in a weak solution of alum—1 oz. of alum in 20 to 30 ozs. of water—and bringing the solution to a temperature of about 100 deg. F., will cause them to disappear when the prints are again dried.

P. E.—You are not quite explicit as to the style of title you require, white letters on black ground, or black on white. We do not know of any method of obtaining the latter except by using a photograph from a typed original. We do not know of any method in which thin celluloid is used, but we have seen successful results from type printed upon thin sheet gelatine. We rather fancy that the celluloid would not take the ink evenly, and it is difficult to secure perfect adhesion. The type impression would require dusting with bronze powder while wet to secure sufficient opacity.

G. W.—Potass ferrocyanide figures sometimes in developer formulæ and appears to have originated many years ago in the United States. So far as we know there is no material advantage in using it, and we should have thought that its appearance in developing formulæ had been abandoned many years ago. We know nothing about the plates that you are using, but if they fog we think that the best thing you can do is to add extra bromide to an ordinary pyro soda developer, up to, say, 2 grs. per oz. of working developer, or use a pyrocatechin developer made up according to the formula in the Almanac.

J. A. L.—It has not been our experience that parts of a bromide print, which have been reduced with iodine and cyanide, afterwards turned brown in colour either by exposure to the light or through other causes. We do not know what the cause may be in your case, possibly insufficient fixation of the original print. If plain cyanide solution reduces the print with sufficient activity (it usually does not) there is no reason against using it, but we should think it will have to be used in considerably stronger concentration than if combined with iodine, and one does not care to use more of such a poisonous solution than one can help.

P. F.—Most certainly the platinum residues are worth attention. Exhausted developers—and the acid baths if in quantity—are mixed in a large jar, with zinc and hydrochloric acid (spirits of salt will do). A dirty chalk-like precipitate is accumulated, and the clear liquor is thrown away. The platinum is precipitated in the mud, and the latter, when enough has accumulated, is sent to the refiners, after being drained from water as much as possible on a linen cloth. Waste prints, clippings from paper, etc., should be sent as they are or burnt to an ash in a place free from draught, such as a biscuit tin with a row of holes about half way up. They should not be mixed with the wet residues, as the two require different treatment for the extraction of the metal.

K. T.—(1) You can work in the manner you suggest if you are not particular as to quality. (2) If the plate has been exposed to a negative image. You cannot get a direct positive from the object in this way. The formula you give should answer with ordinary plates if you do not omit the ammonia. Like most other developing agents hydroquinone requires the presence of an alkali. Try the effect of a strip exposure, giving, with a small stop, say, one second to 16 seconds, and develop. From the resulting negative you will be able to pick out the correct exposure, and from this you can calculate the speed for larger openings. We do not think that any time is saved by combining developing and fixing. If you use a strong developer and about an 8-oz. hypo solution the total time taken will not be greater.

E. E.—The copyright of the photographs belongs to the individual who gave the order for the photographs, that is to say, the person whose photograph and that of his daughter have been reproduced. He can take action against the newspapers for infringement of his copyright, and, so far as we know, the newspaper has no good defence and cannot claim innocence in respect to the matter since they must assume that there was copyright in the photograph, and it is no defence, according to the Copyright Act, for them to say that they thought the copyright belonged to the person who submitted the photographs to them, whereas, in fact, it belongs to somebody else. We should think this would be a sufficient remedy for the father and daughter, since no doubt the newspaper would then take steps against the person by whom the photograph was submitted to them.

A. G.—(1) The paper is of the bromide type. (2) The following method will be found to give bright vigorous prints from flat negatives:—Expose the bromide paper in the usual way, developing it as long as any increase in depth is seen to be gained, ignoring altogether the discoloration of the high-lights—overdevelop it, in fact. After fixing and washing, pour over it the following reducing solution until it is seen to be considerably lighter; when it is, at once plunge into clean hypo for a few minutes. If it is not yet light enough it may be again washed, treated with reducer, and fixed. When it is seen that any further reduction will render the blacks grey, it is washed and dried. Many a negative otherwise quite useless may in this way be saved.

Potassium iodide	30 grs.	6.8 gms.
Water	10 ozs.	1,000 c.c.s.
Iodine	3 grs.	0.7 gm.

With this bath the whites of the print will assume a dark blue tint, owing to the formation of iodide of starch due to the sizing of the paper; this immediately vanishes upon placing in the hypo fixing solution.

SUMMARY

The coming-of-age Congress of the Professional Photographers' Association opened on Monday last, when the exhibition of portraits and of trade exhibits was officially opened by the Earl of Carnarvon. (P. 547.)

The exhibits of professional portraiture are the most notable which have ever been brought together in this country, both as regards quality and number. In the British section the highest award was made to Mesdames Morter and the second to Mr Herbert Lambert. (P. 547.)

Some notes on the exhibition of portraits by Mr. F. C Tilney will be found on page 554.

Delegates from Canada and the United States were present at the opening of the Congress. Mr. Pirie Macdonald, for the latter country, made an eloquent appeal for close co-operation between the English-speaking peoples. (P. 549.)

The president, Mr. Swan Watson, of Edinburgh, delivered an interesting address, in which he illustrated the various types of lighting of portraiture from examples of the work of notable painters of portraits. He raised a question of the superiority of the habitual expression on a sitter's face in preference to a passing phase as a means of obtaining a real likeness. (P. 550.)

The trade exhibits at the Congress are shown on stands uniformly constructed by the P.P.A., and include goods by well-known firms and several quite new introductions. (P. 553.)

Mr. Alexander Corbett will be formally elected president of the P.P.A. during the course of the week. A portrait and notice appear on page 558.

The Salon opened at 5a, Pall Mall East on Monday last, and contains a still greater proportion of portraiture than has been the case even of late years. Appreciations by Mr. F. C. Tilney of some of the notable work form an article on page 555.

In a leading article we refer to some of the chief causes concerned in the accidental production of unsharp negatives. (P. 547.)

The suggestion may be made that lenses may be protected from the action of dust or fumes, whilst exhibited in dealers' windows, by the provision of an extra cap having a clear glass front. The latter would protect the lens itself, whilst not diminishing the effectiveness of the display in the window. (P. 546.)

An inexpensive igniter of flash powder is described in a paragraph in "Assistants' Notes." (P. 559.)

The running of a studio establishment may often benefit by the help given by travellers of the manufacturing firms who are themselves experienced workers. (P 546.)

EX CATHEDRA.

The Congress. A first glance round the Princes Galleries, Piccadilly, on Monday last, was sufficient to show the host of attractions which the Council of the P.P.A. had provided for members attending the "coming-of-age" Congress. Last week we showed the very full programme of lectures, discussions and visits which had been arranged, but the galleries provided a revelation of the comprehensive scale on which the exhibition had been planned and carried out. We refer elsewhere to the important collections of British and foreign professional photographic portraiture, forming a great international demonstration of the art of the photographic portraitist. Everyone must admit that this exhibition must add to the status and importance of portrait photography, and in the long run cannot help benefitting every studio which has an artistic aim in its work. On the technical side, the exhibition of apparatus and materials by manufacturers brought the ways and means of practical portraiture before photographers in the best possible manner. The stands were all constructed of a uniform pattern by the P.P.A., and were individually furnished and internally decorated by the various exhibitors. The credit for this part of the organisation must be given chiefly to Mr. F. Wakefield, who has worked with prodigious energy to make this part of the Congress a success, and who is to be congratulated on his efforts. Altogether, the Congress forms the most notable event in the history of the Association, and one which should strengthen and extend its future influence.

* * *

The Commercial Assistant. The budding operator, especially on the "commercial" side, is apt to prove himself unduly when he finds himself able to produce a technically satisfying negative with fair regularity. While the cleverest photographer does not always get a perfect negative, it must not be supposed that it is only a matter of obtaining accurate exposure and development. These can be so well standardised, and plates are so excellent, that only extremely adverse conditions should excuse a poor negative or print. The young photographer, like the public, thinks that to point the camera at a subject and to perform the functions of focussing and all the rest of it, is what the work of the photographer consists of. The hardened commercial operator knows different. He has to know how to persuade a group of grinning urchins that the wall just clear of the shop window is a much better background. He has to know that a silver cup will look like a cast-iron one if he takes it in a library full of sombre printed books. He has to cultivate a general knowledge of technical terms and points in all sorts of trades. The knack of being "all things to all men" is a very great asset to a commercial photographer.

Assistants and Travellers. It is no uncommon experience for a commercial traveller to be asked for names of suitable probables to fill a vacancy on the staff of a customer. While this form of labour exchange can be said to have much in its favour, there seems to be more than a passive neglect on the part of some employers to permit of meetings between their assistants and such representatives as call upon them. If it be the fear of losing a valued assistant that prompts this very general attitude, it suggests that the assistant has reason for a wish to change, but it may be said at once that the best assistants are those who have opportunities of learning what is going on in the profession. Many of the best travellers have been recruited from the profession, and in an informal stroll around the workrooms can sometimes bring forth suggestions that may be of much more far-reaching benefit to all concerned, that the question, say, of a fractional discount off a few gross of paper. We do not think that the fear of communicating trade methods which are thought to be unique need be a deterrent from thus bringing the technical trade traveller in touch with assistants in the workrooms. Photography has now become so exclusively the practice of well-known methods that it is inconceivable that a business may be injured by showing a firm's traveller all the ordinary details of its working.

* * *

Veiling on Lens Surfaces. We have noticed lately the prevalence of veiling on the surfaces of many high-class lenses, which are fitted to cameras offered for sale. These cameras and lenses are invariably shown in shop windows, and we feel that this veiling is caused principally by exposure to air and fumes, especially in the case of gas-lit premises. While direct sunlight cannot improve the surface of a lens, we are sure that it is not the primary cause of the veiling. It is, perhaps, unfortunate that good class lenses must be exhibited to the public in shop windows at all, as fumes, air, and dust in combination all help to deteriorate the surface in some way. Again, the necessity of constantly cleaning the lens surface from accumulation of dust is liable to cause slight scratching, which does not improve the brilliancy or polish of the lens. Naturally, the camera is not so effective a salesman when closed, so that it has to be shown to the public in its entirety. Some time ago, folding cardboard covers were supplied to dealers to be placed over the bellows of cameras, when exhibited in the shop window. This was a move in the right direction, but it did not offer any protection for the lens itself. The lens is undoubtedly the most vital part of the camera, and should be protected from the elements as well as from chance injury.

* * *

A Sales Lens Cap. We suggest, therefore, that each high-priced lens, and possibly those of lesser value, whether fitted to a camera or not, should be supplied to the dealer, with a loose cap, fitted with a clear glass front and made to cover the front combination completely. The ordinary cap is useless for the purpose, as it does not allow the lens to be seen without its removal. This cap could be made in either card or metal, the important point being that it should fit fairly tightly, and therefore exclude air and dust from the lens surface. The back combination of the lens is naturally protected by being inside the camera, and does not require any further covering, but the glass front of this protection cap would allow the prospective buyer to read the name of the lens maker and any other particulars, focus, stop value, etc., usually engraved on the front of the lens tube, so that no loss of advertisement would ensue. The cap would be of no use photographically, its only purpose being as a protection to the lens surface whilst the apparatus was in the dealer's possession. It could therefore be removed when a sale was effected, or if the dealer so wished could be supplied to the customer. The cost of such a lens protector would be quite trivial, and the lens would gain by being kept quite clean and free from chances of veiling.

UNSHARP NEGATIVES.

We have not in our mind such negatives as are of design unsharp or softly defined, but such as were intended to be perfectly sharp, and have failed to come up to expectations. Unsharpness may be due to one or more of many causes, some of which can be detected by simple inspection, while others are only manifest in the finished negative.

In tracing the cause of poor definition it is a good plan to start by examining the image upon the focussing screen, using a very sharp, well-printed page from a magazine or newspaper as a test object. The ground glass should be of the finest possible grain and, if new, should be rubbed with a little sweet oil or fat, as much as possible being polished off with tissue paper. A focussing eye-piece is needed by nearly every observer, unless possessed of extremely good eyesight at close quarters. With apparatus being in perfect condition, many cases of unsharpness are due entirely to the bad focussing. If it be found that it is impossible to get the smaller types on the page sharp enough to be read distinctly upon the ground glass, the defect known as spherical aberration is indicated. This is usually only present when the lens has a large aperture, and should disappear when the opening is reduced to $f/16$. This defect is sometimes present in high-class anastigmats of large aperture, say, $f/3$ to $f/4.5$, but is usually eliminated by stopping down to $f/6$, or thereabouts. If a reduction of aperture does not ensure sharpness, the trouble is probably due either to faulty centering of the lens components or to what is known as "bad figuring," that is to say, the curves are not truly spherical. It may also be due to stress having been put upon the glass by reason of a fall or other accident which has, sometimes invisibly, distorted the brass mounting. If the lens is of any value it is advisable to place it in the hands of a competent optician for overhauling, but if a cheap type of lens, it is better to discard it altogether, as the cost of correction, even if possible, would not be justified by the result.

If the image upon the ground glass appears to be perfectly sharp, a plate should be exposed and developed and, after drying, examined with a magnifier. That used for focussing is the most suitable. The reason for drying the negative before examination is to obviate the appearance of unsharpness caused by the swelling of the gelatine, which is considerable with some emulsions. If the image does not appear to be sharp, it may be due either to chromatic aberration in the lens or to want of registration between the ground glass and dark slide, and as the latter is the easiest to detect, it is as well to test for this first. This is done either by using a simple depth gauge made of a stout lath or flat ruler, having an ordinary screw fixed in the centre. The lath is laid across the ground glass frame and the screw turned until the point just touches the ground surface. It is then placed in the same position on the frame of the dark-slide, when the screw point should just touch the film of an old negative which has been placed in the slide. If there is any discrepancy, the ground-glass

screen should be packed up or sunk as needed. Each slide should be tested as, although externally similar, there may be a slight difference in their register. It should be noted that in slides which fall from the front, a difference in the thickness of the plates will sometimes be enough to affect the definition when a lens of large aperture is being used.

If the register be correct, chromatic aberration may be looked for. The simplest test for an unscientific worker is made by placing a large sheet or strip of printed paper at an angle of about 30 degs. to the axis of the lens. In the centre of the paper, a ring about an inch in diameter should be marked in pencil, and this point should be very carefully focussed on the exact centre of the plate. Upon exposing a plate, the lettering inside the ring will be perfectly sharp if the chromatic correction is all right, but if any portion outside the ring is sharper than that inside, it is not. It is rare to find this defect in high-class modern lenses, but if there be any suspicion of it the maker should be consulted, as it is to his interest as well as to that of the lens owner that it should be rectified.

An often unsuspected cause of unsharpness is wear in the camera fittings, which allow a slight change in the position of the back or front between focussing and exposure. For instance, if the rack adjustment be somewhat loose, it may slip a tooth or two while inserting the dark slide or drawing the shutter. Again, the clamping screws of the swing-back may not grip properly, allowing of a similar movement, while the front of the camera may be slightly displaced by the act of setting the shutter.

The tripod is not always to be relied upon; even an old and trusted stand will get a little shaky in the knees with long use and cause a slight tremble, not enough to give a double outline, but enough to spoil the definition.

When the greatest sharpness is necessary, care must be taken that the grain of the emulsion is fine enough to do justice to the lens. The selection may be made in a rough way by copying a piece of very sharp printed matter upon a slow lantern plate, and using this as a standard of comparison, with negatives made of the same subject, with the same lens upon the plates to be tested. With a pocket lens it can easily be seen whether the definition approaches that of the slow plate.

It must not, however, be assumed that the granularity of the image bears any definite relation to the speed of the emulsion, for lately great improvements have been made in rapid emulsions. For this reason it is desirable to make comparative tests with plates which may bear the same speed number.

THE P.P.A. CONGRESS.

The first two days of the Congress which have passed up to the time of our going to press have demonstrated its emphatic success, and have amply dissipated any doubts which some may have had of the success which would attend the experiment of a Congress in Piccadilly in September. The exhibition of portraiture, or rather "exhibitions," for there are several of them, must have surprised everyone who was not in the secrets of the organisers. The British section, running to 250 pictures, is undoubtedly the finest collection of professional portraiture which has ever been brought together, and, moreover, includes work by notable photographers who have not previously been seen in these shows. The technical and commercial section, although not large, contains a considerable variety of work serving to emphasise the importance and high standard of quality attaching to this branch of photography. Notable in it are the copies of paintings by Henry Dixon & Son and William E. Gray; architecture by R. G. Randall and E. J. F. Wilkinson; engineering subjects by Charles F. Dickinson; motor cars and other subjects by F. Wakefield, and photographs of wireless apparatus by D. Charles. There is also a small press section of approximately current news photographs, which, at any rate, serves to bring to notice the important part which news photography occupies in modern journalism.

In the foreign section of professional portraiture perhaps the exhibit which artistically is of the greatest interest is that of Emilio Sommariva. The French and Belgian division exhibits marvellously fine technique in many instances, particularly the prints by M. P. Apers, of Paris, himself a visitor to the Congress. The United States sends a very large section, and that contributed by Scandinavian photographers contains the work of leaders, such as Dr. Henry B. Goodwin and F. Flodin, both of whom are personally known to many photographers in this country.

Following the official opening of the Congress by Mr. Swan Watson, some interesting speeches, which we report below, were delivered by the delegates from Canada and the United States, Messrs. Kennedy and Aylett, from Toronto, and Mr. Pirie Macdonald, from New York. The president, in his address, drew a series of lessons from the works of great painters to be seen in our own and the Continental galleries, particularly in reference to the preference for the habitual instead of the passing expression in a sitter as a means of satisfactory likeness. He also referred to the absence of a positive smile in portraits of children by the great Masters, and further illustrated the different types of lighting, including some which are often thought to be quite recent discoveries, which are to be found in the portraits by the great painters.

As is shown from the programme, which has already been published, Congress members may have the busiest of weeks, if they take advantage of all the fixtures which have been provided. Many, no doubt, will choose here and there and combine the items which specially interest them with visits to the manufacturers' exhibits and to non-photographic recreation in London. The studios of the following photographers are being visited by courteous permission of the proprietors: Madame Yevonde, Messrs. Arthur Banfield, Angus Basil, Alexander Corbett, Reginald Haines, Lafayette, Ltd., Hana Studios, Ltd., and J. Russell & Sons. By the time the present issue is published the Congress will have almost come to its conclusion, so that reports of the lectures and meetings figuring in the latter part of it must be held over for appearance next week.

The following awards were made by the judges, the Earl of Carnarvon and Messrs. Furley Lewis, J. B. B. Wellington and H. W. Bennett:

British: Silver gilt—"Master of the Hounds" (No. 237), by Messdames Morter; Silver—"Punkey" (No. 164), by Herbert Lambert; Bronze—"Well known in our Village" (No. 181), by Miss Daisy Day. Foreign (excluding British Dominions and United States): Silver gilt—no award. Silver—Study (No. 449a) by M. Dante. Bronze—No. 471, by Shaun Wyndham.

Canada: Silver gilt—no award. Bronze—No. 725, by John Kennedy.

United States: Silver gilt—No. 591, by Richard Dooner. Bronze—No. 750, by J. Vanderpant.

Commercial: Bronze—Copy of painting "The Strawberry Girl," by Reynolds (No. 279), by William E. Gray.

Press: Silver medal—Princess Mary's Wedding (No. 254), by the "Daily Mail."

A special award of a silver medal was made by the judges to Signore Emilio Sommariva, of Milan, for the series of portraits (Nos. 313-343).

OPENING OF CONGRESS AND EXHIBITION.

The official opening of the International Exhibition took place at noon on Monday, September 11. The Right Hon. the Earl of Carnarvon was accompanied on the platform by Mr. Swan Watson (President of the Association), Mr. Alexander Corbett, and Mr. R. N. Speaight.

The Earl of Carnarvon said: It is with a little diffidence that I am here to-day to open this very important Exhibition. I had hoped to have seen a very distinguished person occupying this place. He would have been far better fitted than I am to perform the task assigned to me, although perhaps he might not have known as much about photography, for it has been a hobby of mine for many years. But, as you are aware, many people whom we should have liked to have had with us are away from London at this time of year, and therefore I hope you will be satisfied with me as a poor substitute.

For many years, ever since I was a boy at school, I have followed photography with keen interest. I well remember being given a small camera which contained a sensitising bath and everything complete. I cannot say that the results were very marvellous; certainly they would not rank with anything at all produced to-day, but to my youthful imagination they were perfectly enchanting. There have been more epochs than one in the history of photography since those days. One epoch was signalised by the introduction of dry plates, which made photography easier, simpler, and cleaner than it had ever been before. Another was marked by the advent of the Kodak and films, which made photography possible to everybody. And there has been a third period, during which the original ideal of pin-point sharpness, of painfully accurate reproduction, has been departed from, alike in landscapes and portraits, and we have arrived at a more artistic conception. From a glance at these exhibits I think you will gather that in this direction modern photography has made enormous strides. No longer have we the hard, matter-of-fact reproduction of years ago, but there is evidence of a genuine effort to produce something which pleases and which evidences the personal feeling of the producer and his taste in selection.

But I must not be led away by personal recollections, for I want to say a few words about this Association. Originally it was started by five leading photographers—I think in London—and I am glad to say that some of the five are present here to-day. Well, the Association grew and grew, and although for a period it did not grow perhaps quite as quickly as might have been desired, it has now reached a membership of over 1,200. I think that a great debt of gratitude is due to those original five. If it had not been for them it is possible that the movement would not have started, at all events it would not have started so soon. But the puny infant is now a strong man. Amongst the objects of the Association the protection of the photographer remains always paramount. It is ready also to assist all photographers. It is not an association merely for the benefit of Bond Street photographers—by which I do not mean that all the leading photographers belong to Bond Street, but the expression stands for the photographers who are at the tip-top—but it is ready to help even the gentleman who stands on the beach, armed with a sort of cannon, and photographs you for twopence, frame included! Unlike a great many associations, this one really does very hard work. The Council meets once a month, and sometimes sits for four hours. Its enterprise has been illustrated lately by its publication of a magazine. I feel that every support ought to be given to the Association by professional photographers. When you get a very large number of people of a single trade or profession banded together it is probable that their interests will be very well looked after.

As regards the Exhibition to-day, I dare not say very much, except that the examples are remarkably fine. What is perhaps a striking point is that while the Association has previously held exhibitions, this is the first International Exhibition on which it has ventured. We have exhibits here from practically all the countries of Europe, and from America and the Dominions. I do not think there could have been such a representative collection had it not been for the kindly offices of the Ambassadors in this and other countries. In the room in which we are met all the exhibits are British, and I think we may say that the British compares very well with the other sections. That must be a source of satisfaction to everybody here. Besides the exhibition on the walls, there is in the next room a trade exhibition, where you will find all the latest adjuncts necessary to the photographic art. The only thing I should like to add is that the best thanks of everybody are due to the committee which has had charge of the selection and hanging. They have done their work most excellently. I now declare the Exhibition open.

Mr. R. N. Speaight proposed a hearty vote of thanks to Lord Carnarvon for his kindness in opening the Exhibition. He had honoured the professional photographers, not only of Great Britain, but of all countries. Many thanks were due, as his Lordship had said, to the Ambassadors and Ministers resident in this country, and also to the secretaries of photographic societies abroad. The Earl had referred to the Association as now a fully grown man. Certainly it had reached its twenty-first birthday, but in the eyes of many people it was not yet old enough to walk alone, and there was considerable uncertainty when it started its steps this year without a guiding hand. He would not say that it had learned to walk, but certainly it had learned to stand alone, and if the present Exhibition proved the success it promised to be, they could look forward to far bigger things in the future. They were indebted to Lord Carnarvon for acting as one of the judges, and he hoped that when the time came for the pictures to be returned, a *résumé* of his Lordship's remarks would be sent with them, for that would do much to help professional photography forward.

Mr. Pirie Macdonald seconded the vote of thanks, on behalf of the newly-affiliated Professional Photographers' Society of America and also on behalf of the Canadian brethren. The Exhibition was part of the grand scheme which was in course of development to unite the English-speaking peoples of the world. The Exhibition was going to do much to make the American photographer feel that he was a part of that great united body which was going to carry a genuine civilisation throughout the world. They in America had a feeling of intense cordiality for Great Britain, in token of which he had been sent there as delegate. The invitation to America to exhibit in this British show was a sign that the British wanted the Americans to walk with them along the same road.

The vote of thanks was carried in Scottish fashion with three vigorous hand-clappings, and Lord Carnarvon, in acknowledgment, said that he was always ready in whatever small way he could to help the Association.

THE PRESIDENT'S WELCOME AND RECEPTION OF DELEGATES.

Addressing the members on Monday evening, the President, Mr. Swan Watson said:—It is my great pleasure to welcome you to the 1922 Congress of the Professional Photographers' Association of Great Britain and Ireland.

It is our twenty-first birthday—no ordinary occasion. Twenty-first birthdays are usually associated with newness of life and freshness of hope; the past has been our childhood, our training: it will soon be forgotten; the future opens out with widening possibilities.

Twenty-first birthdays are usually associated with congratulations. Here let me record:—From Rome, the Eternal City, Signore Bettini, Signore Bonaventura, and Cav. Felici send you their salutations. The same exultant spirit comes from Signore Socci of Florence, principal of the world-famed house of Alinari.

From Paris—Messieurs Benjamin, Manuel, Melcy, Nadar, and Reutlinger send you greetings and congratulations.

Ferdinand Flodin, of Stockholm, writes: "I regret exceed-

ingly not to be able to be present at your Congress, but extend to you, as its representative, my heartfelt wishes for a successful time." Dr. Goodwin, of the same Northern capital, wishes you a joyful time.

From our sister country, America, J. C. Abel—a photographic power in the United States—writes: "I wish you the very greatest success with your coming Congress, and I trust that the visit of Pirie Macdonald and the exhibition of American work alongside the British work will help to cement the friendly relations between our countries still further. Kindly extend to your members my very best wishes and expressions of goodwill, and tell them we shall certainly look for some of them over here next year and another great collection of British work." With such good wishes pursuing us, my friends, we ought to be happy.

On twenty-first birthdays we don't say much about the past. It is the future we look to. We could not have been without the past, and the year that is gone is perhaps a memorable one. I do not want to trespass on the Secretary's report, but two things stand out. The Association has become an incorporated society, with all the prestige of such a body, and last year was the genesis of our own journal—"The Record of Photography"—a magazine destined to help its professionals.

The future of professional photography to me has never seemed so great, notwithstanding that I am fully conscious of the great industrial unrest and lack of business. A professor of medicine said to me that every text-book of medicine that was ten years old was out of date. Photography is in much the same position.

Only, let us remember, let the younger generation be taught: we must keep moving, and it is this that will create respect for our profession. The future photographer must be well educated. If he can go to the university and take a degree before he starts, including in his subjects psychology, fine art, chemistry, light and optics, he will be a better photographer. Some artists are now doing this.

We cannot all do this, especially we who have just turned our twentieth year, but we can keep our ears close to the ground, our intellect continually on the alert and active, and our spare moments—if we have any—to the widening of our knowledge.

Last year has brought the Association the service of a secretary who devotes his whole time to its interest. Mr. Alfred Ellis is a gentleman of wide experience and of great worldly wisdom. What he does not know about the photographer's interests is not worth knowing.

The President's address was preceded by the introduction of guests from overseas in the persons of Mr. J. Kennedy and Mr. Charles Aylett, both of Toronto, and Mr. Pirie Macdonald, of the United States. An effective musical programme was arranged, whereby "The Maple Leaf" was sung in honour of the Canadians, and "My Country, 'tis of Thee," in honour of of the American. When, later, Mr. Pirie Macdonald handed a beautiful American flag into the custody of the Association "The Star-Spangled Banner" was sung.

Mr. Kennedy thanked the members for the reception accorded to him and his colleague. The Canadian delegation consisted of Mr. Aylett and himself and their ladies. It was not the fault of Mr. Reginald Haines that it did not consist of twenty-five or more, but the distance was great, and some were too busy to come, and the finances of others would not permit of it. In Canada they were told that London photographers were rather high and mighty people, but he and Mr. Aylett had found themselves quite at home. Their visit was the direct result of coming into contact with that "genial, chubby little member of the Council," Mr. Haines, who made many friends in America and Canada. During their visit to this country Mr. Haines also had acted as a delightful host, showing them everything in London that was worth seeing, and motoring them many miles in the country. They felt amply repaid for their visit already by seeing the beautiful work on the walls of the exhibition. He had attended American conventions for rather more than twenty-five years, and had never seen such a beautiful collection of professional work, though he had seen larger collections, for in America they were accustomed to "miles of it." He added a few words in appreciation of Mr. Macdonald, who, he said, had a genuine love of England, and did not "put it on" when he came over here. In fostering British sentiment in America during the war Mr. Macdonald had done a great work.

Mr. Aylett also expressed his gratitude for the reception which the Canadian visitors had been accorded, and brought the greetings of the Ontario Society of Photographers. He had already learnt so much from his stay in England that he wanted to get back and do some work. Rupert Brooke had said of England, that it was a land from which men of splendid hearts went out, but he thought it was a land where men of splendid hearts remained all the time.

Mr. Pirie Macdonald began by saying that he was not a bit nervous. The honour that had been done him was quite of a piece with all that he had been accustomed to expect from Englishmen. He had, nevertheless, a tremendous responsibility. It was seldom that a man had the opportunity of representing an association of two thousand people. He went on to refer to the feeling in America during the early part of the war. He himself was the son of a British father and a British mother, and fifty years ago, at the time he was a youngster, to live in the United States was not an easy thing for a person who spoke the English language with the clarity with which they were accustomed to speak it, as compared with the jargon of the American mob. He was made the mark of many a missile, and he had to fight his way through in some communities that were at that time full of hatred against England. He got through, not maimed at all, either in body or spirit. During the last fifty years there had been the inevitable growing together of a thing which was naturally one. During the war, in a profession which was made up of a large proportion of Germans—half of them perhaps of German birth—they arrived at any rate at a point where they were fifty per cent. for Britain. He himself paid no attention to a man's birth when he spoke during the war. He toured the country from one end to the other, spending thousands of dollars and many sleepless nights, in his effort to point out what to him was the only course for Americans to pursue.

Britons and Americans had the same language, and even among the Germans in America, in the second generation, they had learned to speak in English and not in German. Therefore they thought in English, and English had not that quality of elision, whereby some words might sound like one thing and mean quite another. The basis of the common life of both the British and the American people was the law that was started in their hearts even before the Magna Charta. It meant that these two peoples had the same sentiments regarding justice, the same ideas as to the separation of right from wrong. During the fifty years of which he had spoken, one veil after another had been lifted. There were other veils which still remained, but they too in time would be lifted. Destiny was a word to play with. It was used alike by the Bohemian and the "high-brow," each to his own purpose. But there was something in the word. It meant the end to which they must travel. Destiny was not something ready made; it was something they made for themselves. Destiny was always the child of desire. He had a feeling that there was a destiny for these two nations if they desired it—that is to say, if the individuals composing them desired it. For his own part, he desired above all things the unity of the English-speaking peoples of the world. If that was the desire of those to whom he spoke, there was a work which every one of them could do to bring it about.

Mr. Macdonald added that when the extension of the affiliated membership was made, so that each member of the Professional Photographers' Association in Great Britain was automatically made a member of the Photographers' Association of America, there came a feeling that there ought to be, in

British hands, a symbol whereby the friends on this side of the water might visualise the friends on the other. They had, therefore, sent by his hands their most revered emblem—a thing which occupied in their hearts the same place of reverence as the Union Jack in the hearts of the people of this country.

A large and beautiful example of the Stars and Stripes was then unfolded, amid loud applause, all those present standing.

Mr. Reginald Haines asked Mr. Macdonald to accept the thanks of the Association for this beautiful gift. The flag was beautifully wrought in itself, and yet far more beautiful because of the sentiment which clung to it. When, last year, he had the honour of conveying the Union Jack to Buffalo, he little thought that from so small a beginning, and with so insignificant an instrument, there would result such a thing as the presence of these overseas visitors at their own Congress. It was a great honour to have with them three men who had travelled over 7,000 miles to be present. He recited some of the memories of "Old Glory," which bound the American people together. There was no man they were better pleased to see on this side than Mr. Pirie Macdonald. He had won a foremost position, not only by his photographic work, but also by his virility, his personal magnetism, and his singular capacity for inspiring the people with whom he came in contact, whether on one side of the Atlantic or the other. The Americans believed that it was very necessary "to know the other man." He wished that that feeling, so evident at Buffalo, could be transplanted here. Both he and Mr. Macdonald happened to belong to a brotherhood—the Rotary Fellowship—one of whose leading ideas was fellowship not only between nations, but between men.

The President welcomed a French visitor, M. Apers, who was among them, and in a few words, spoken in French, M. Apers spoke of his enthusiastic admiration for the pictures exhibited, and his pleasure at being among British photographers.

Mr. Frank Brown then called upon the President to deliver his address from the Chair. Mr. Swan Watson, he said, was happy in his year of office by reason of the immense success of the Exhibition, and the presence of so many distinguished visitors.

The President prefaced his address with the remark that it was usual on a twenty-first birthday to bring gifts, and he would respectfully suggest that a very appropriate gift from the members to the Association would be for each of them to make his subscription a guinea instead of half a guinea. At the close of the addresss Mr. Frank Brown moved a hearty vote of thanks, which was seconded by Mr. Alexander Corbett, and carried with the singing of "For he's a jolly good fellow."

SOME EUROPEAN PORTRAITS WITH SOME TENDENCIES IN MODERN PORTRAITURE BY PHOTOGRAPHY.

For the rest of the evening, as most of us are engaged in portrait photography, I propose to show you some portraits by European artists. Afterwards I hope to show you some modern portraits by foreign photographers.

It seems to me, generally speaking, that the majority of painters have adopted one of two forms of lighting their portraits. First, they have placed their sitters where the shadow side of the face is furthest from them, the light being directed from the top and slightly from one side. This lighting, known as the 45 angle, is by far the most common and, in the majority of cases, gives the surest likeness. From the days that Cimabue painted his Madonna, Macassio his Adam and Eve, and Botticelli his Venus, down to the latest Academician, this has been the favourite light. In my judgment it is the first we ought to teach apprentices. When they have mastered this they can experiment with shadow lighting, always keeping likeness in their mind. It gives the centre of the face in light, the further side in shadow, and the side nearest the light just a little lower in tone than the centre of the face. Famous portraits are typical examples, e.g., Leonardo Da Vinci, that famous painter, chemist, poet, engineer, and wizard, by his own brush; Michael Angelo, the architect of the dome of St. Peter's at Rome, the painter of the Sistine Chapel, and noted sculptor, by his own brush; Angelo Doni, friend of Raphael, the same lighting, but a lighter background; Fornarina, the girl that Raphael loved.

Coming down the centuries into France, there is the portrait of Marie Antoinette by that gifted French artist Madame Vigée le Brun, note the pose of the hands, the line of the dress; the daughter of Vigée le Brun; Napoleon, by Delaroche, in which the position of the right arm and the downward pose of head and expression are to be noted. Then there are Nattier's Madame Henriette de France and our own George Frederick Watts, by himself.

The second form of lighting that artists have used extensively is that of painting the face with the shadow side nearest the painter. The principal light is directed from behind the sitter, with a subsidiary light in front. This means that the principal light is more or less on the outline, furthest from the painter. This lighting has been extremely popular through the centuries. It gives more light and shade, and perhaps more roundness. The early photographers erred on the side of too much shadow. This kind of lighting seems to be on the wane, both with painters and photographers. I may refer to the famous picture of Beatrice Cenci from the Barberini Palace, Rome, by Guido Reni; to Marco Polo, by Titian; to Raphael's Pope Julius, that terrific warrior Pope. In this portrait the eye is looking further down than the spectator; not many photographs are taken like that. In the portrait of Madame de Pompadour, by La Tour, you should notice the lowness of the point of view of the painter (or, as we should say, the camera), much below the face; also the leaves of the music, the arrangement of the articles on the table, the books at the foot of the table, and lastly the feet. Would you have posed them thus? Other examples of this lighting are Dr. Schomberg, by Gainsborough, in Tate Gallery, and Mrs. Siddons, by Sir Thomas Lawrence.

While most portraits throughout the centuries have been painted on these lines, there are one or two other systems which have been adopted by individual artists. There is a kind of lighting which is mostly from the top. As typical examples, perhaps the eminent scientists, Darwin and Huxley, may be cited. They are painted by the Hon. John Collier. This kind of lighting puts a certain amount of shadow on the whole face, and has a tendency to give a sense of gravity to the expression.

That great master of light and shade, Rembrandt, had methods all his own. To him shadow was of infinitely more value than light. In many of the portraits, which I have personally studied in the galleries on the Continent, I find that only about one-twelfth of the picture is in light; the other eleven-twelfths is in mystic shadow.

Notable examples of Rembrandt's art are the portrait of himself, from the Berlin Museum; the portrait of Sobieski; and Rembrandt, from the Louvre.

This form of lighting gives great strength of character, and it seems to me that just in proportion as shadow in daily life leaves its mark upon us more than success, so I think these portraits are more likely to outlive the changing fashions of lighter pictures or fancy lightings.

The kind of lighting in his Jewish Rabbi is possibly not suited for children. Many a time have I looked in the galleries for a child by Rembrandt, but have never found one. Even his young bride Saskia, and his girl with the broom are treated to shadow. It may be noted that he seldom lets any light run out of his picture.

His "The Syndicate of the Drapers," from the Rvks Museum, Amsterdam, taught me the value of a thick tapestry cloth. You get magnificent folds.

Poor Rembrandt! He knew what success was, even to overflowing. He also knew, at the last, the bitterness of failure. But these three hundred years have not diminished his power. To us he stands as a living inspiration. All his forms of lighting in his portraits are possible in photography. Remember, too, he knew nothing of the powers of electric light.

There is another kind of lighting found in some portraits in the galleries, which is charmingly elusive. It is, perhaps, an effect of lighting rather than a particular form. I refer to that kind of lighting in which one part of the face is thrown into shadow by hat or hand.

In the La Femme au Chapeau de Paille, by Peter Paul Reubens, the light is simply delightful, but difficult to do in photography. Note the light is on the shadow side of the cheek, an anticipation of spot lighting three hundred years ago; note it is all daylight.

The portrait of Madame Vigée le Brun, in the National Gallery, painted by herself, inspired by the last picture which she saw at Antwerp. It was she who said "To *paint* and to *live* are the same word to me." How many photographers present could paraphrase that?

In Sir Joshua Reynolds' portrait of himself, in the National Portrait Gallery, you should look at the soft shadow below the hand and on the light side of cheek.

Another portrait in the National Portrait Gallery, that of Thomas Philip, R.A., painted by himself 120 years ago (1802), there is a side light that is now fairly often seen in American portraits by photography. Last year I listened to an eminent photographer, who looking at one of these American portraits exclaimed: "Search all the European galleries and you will not find a light like that on any portrait."

To turn to modern portraiture. Sir William Orpen has painted some portraits in what may be termed a new kind of lighting, and, of course, he has been copied. But oh! how far superior is the master's touch. It is somewhat the same—though not quite the same—as what has become known in photography as spot lighting. It is that of a concentrated light being directed on to a particular part of the face, generally more definite than reflected light, generally too—though not always—on the shadow side. It is not intended to compete with the principal light, but in photography it often does. Sir William Orpen has courteously granted me permission to show you his portrait of Earl Haig.

Later I shall show you some examples of portraiture by photography in this light. Artificial lighting has given much power into the hands of the photographer, but I am not certain that it has given more powers of likeness. Said a Continental photographer to me: "Bring me any portrait from the galleries and I will light one in my studio the same." How many photographers could do that—or would even try—yet I believe this man could.

In the Pitti Gallery at Florence there are four rooms devoted to the portraits of artists. For the most part these are by the painters themselves. Here hang Michael Angelo, Leonardo, Titian, Raphael, Rubens, down to our own day—Millais, Watts, and Sargent. Many a time I have looked at these and wondered what some of these men were thinking about.

On re-visiting this gallery recently, what impressed me most was that on none of those faces was what might be called the "momentary" or "passing expression," produced by some thought entering the mind suddenly and illuminating the face. But in all those faces the expression was one which gave the impression of years of thought—that which made the character what it was.

Coming from the Pitti to the Louvre Gallery, and looking at four portraits of Rembrandt by himself, I found no hint of a thought created a minute before, but, on the faces, the fundamentals of the mind. At times it was a bit of biography; at other times a bit of history. How comes it that these painters chose to paint themselves so? Surely they must have thought the "habitual" was greater than the "passing."

The conviction has been growing upon me that we photographers have erred in aiming at the passing. Have we been endeavouring to get the "momentary" rather than the "habitual." I am disposed to think as a man advances in years, if he is a man of character, that we should give longer exposure and endeavour to get portrayed something of the inner man's mind, which cannot be got by an instantaneous exposure.

Take the instance of a young man. A marvellous change has come over these last years. No portrait of an immaculate Apollo with an irresistable expression is now wanted, but something learned, distinguished, brainy. A touch of ruggedness or severity in most instances will increase your order.

In consternation, one of my young lady assistants told me that there was a young man in who wanted to be taken like Oliver Cromwell. When he entered the studio I asked which portrait. Blushing slightly, he said, "I only don't want my warts removed."

The young lady, too, is now inclining to want a picture "just of herself," not a modernised Juno.

Babies, however, are different; they have comparatively little mind or character. They require to be taken more quickly; besides they may move.

One singular fact is that in examining the paintings of children in the principal galleries of Europe, I do not know of a single instance of a child painted smiling. One does get them interested with that interest that speaks of dawning intelligence, and this is almost divine. Even in the cherubs of Titian—Andrea del Sarto—there is no smile.

In the pictures which I now show I invite you to ask yourself whether the prevailing expression is the transitory one, which might fade before the exposure was over, or is it the habitual. These are Mona Lisa, by Leonardo da Vinci; Rembrandt, from Louvre; Titian; Philippino Lippi.

One morning last year I received a strange invitation—would I go and give an illustrated lecture to 150 men in gaol? Hesitatingly I replied that I doubted if anything I could say or show would interest them. The gentleman thought differently, and reminded me that I would be addressing, among others, some very well educated, and some quite as clever as myself. There was no room to doubt the latter remark, so I went. It was a strange experience, but it left me this impression among many others, that it was the habitual that was the true likeness of the man. The Governor paid me a great compliment on the impression I had made; this I took with the usual "cum grano salis."

In less than a week I was invited to another prison, to give the same lecture, this time to men and women. I went willingly to study the expressions. Again I scanned the faces, asking myself what was the true likeness of these people. Again I came to the conclusion it was the habitual, not the passing.

Here let me introduce to you, illustrating character and long exposure, a group. This had an exposure of two and a-half minutes, and here are two of D. O. Hill, who is reported to have given three minutes' exposure in the sun.

Close akin to the matter of expression is the question—Is it the regular or the irregular in features that gives the character? Most people would answer it is the regular—but is it?

We have all been trained, and have trained our apprentices, to take what was the best side of a man's face. If he had a small eye—put it into shadow. Had he a crooked nose—take the side that shows it least. Did his mouth run up at one side more than the other—to be sure and avoid that side, and so on; so we acted and so we taught.

But I have convinced myself recently that if you take a portrait of a man at what one calls popularly his best side

and one from the other side, and submit two proofs, very often he will order from the wrong-side portrait, for his friends think it is most like him.

A client of mine, some time ago, received three proofs, ordered a dozen each from two of the three negatives and took the third proof somewhat hesitatingly. In less than eleven months a repeat order was given for two dozen more, but from the one that only one copy was taken from; it was—we shall call it the wrong side. A month later the father of the man called and ordered twelve enlargements—quite a tidy order. This, of course, is an isolated case, but I have frequently this experience in a smaller degree.

Here I may refer to the portrait of Coventry Patmore, by Sargent, in the National Portrait Gallery. To look at it most of us would say that the defective eye is towards the light, yet the artist chose that side.

There is a story that Vandyke is said to have painted King Charles—who had only one eye—in profile. The picture was not considered a success. Then he painted him showing the defective eye, and every one said it was excellent likeness If it is a true story it illustrates my point.

Now I will show a few portraits and raise some questions about them.

Portrait of Nell Gwynn, by Sir Peter Lely. Is it ever successful in portraiture by photography to turn the head away from the camera and then turn the eyes back. One does it while listening, but in photography does it not look a little sly?

Here is a portrait of Henry James, the novelist. I would like you to look at it from two points. First there is a theory taught in art schools that there should either be one light in a half-length picture or three lights, one principal and the other two subordinate. Here there are only two—does the picture satisfy you. Note the position of the head on the canvas; if anything it seems low.

Now note the portrait of Sir Henry Taylor, by G. F. Watts. The head is placed much higher than the last; in fact, a little of the hair is actually cut off. Are both pictures right? In looking at a half-length of a man, can you tell me whether he is a tall or short man? The director of the Scottish National Galleries thought it was impossible. But is it?

Let me show you four pictures by the Spanish painter Velasquez. He has much to say to photographers. Here is Pope Innocent X., from the Doria Gallery, Rome. A celebrated Scotch portrait painter told me that he regarded this as one of the masterpieces of the world. When I saw it I agreed with him. Suppose a photographer takes a man with an expression like this—there is nothing to prevent it—will that picture retain its interest as long as this?

Here is Æsop with his book of fairy tales. Look at the attitude; look at the lighting; look at the expression. I cannot quite understand why Velasquez seems to emphasise the feet so often.

Here is Menippus, a wonderful drawing. Few of us photographers can take full lengths of men and abstain from weakness.

Here is the Spanish admiral, Pulido-Pareja, from the National Gallery. Observe the shadow cast from the figure.

Few painters repay the study of the photographer more than our Scotchman, our own Edinburgh man, Raeburn. Here is the portrait of the good man himself. Could you desire any photograph better? Look at the dignity. Look how nicely the left hand at the chin is shaded, though it is turned to the light.

Here is Lord Newton, Scotch judge. Look at the strength; note how the lower part of the figure is shadowed. Is that expression a passing one or the habitual one? A well-executed copy hangs in my home; though severe, I joy to live with it.

Few men would care to go down to posterity in red cap and dressing gown, but Professor Robison was a man of science, connected with our university, where this portrait hangs. Observe the placing of the figure, not the general rule, that you should have more room to front of the face than behind. Note the pose and shadowing of right hand.

MacDonnell of Glengarry, a Highland chief in his ancestral hall. Note the lighting, the shadow on the background, the light on the knee—the strongest in the picture—the expression of the mouth. You need not try to put your salmon rod upon the Garry without permission.

The Macnab, Chief of the Clan. Observe the placing of the figure—the distance this time in front of the figure, the height the camera would have been if it had been a photograph. The light on the leg is again strong. What character on the face! Is that a passing or habitual expression? You need not go on taking an odd shot at a grouse here, or his gillies will run you down.

Ladies and Gentlemen, I love these men; they are true Scots, with all their national instinct. I wish they had been my ancestors.

Robert Louis Stevenson, in his "Virginibus Purisque," thinks that Raeburn's women have not the same marks of character. There is a certain truth in this; still, it cannot be said of them all; a few of them could sum up most men.

We, as photographers, must act much quicker than painters. We have to sum up our subject, decide on the scheme—keeping, if possible the finished portrait in our mind—and photograph our client all in less time than the painter has for his first sitting. If, however, we reverently study how the painter arrives at his finished picture, the spirit of the painter may exchange with the spirit of the photographer, and each to the other's gain.

I now desire to show you a few modern portraits by photography by other than British photographers.

There are a few general tendencies in modern portraiture, not only in this country, not only in America, but in the nations of Europe. These indicate an activity of mental outlook for which there is nothing but praise.

They seem to be eccentricity or affectation—and so they may be to some—but they also may be the beginnings of some new aspect of truth. History is full of instances of heterodoxy in one age becoming the confirmed orthodox belief of the next, so that it behoves us to look at these new things with the open mind.

1. The first tendency is to try other methods of lighting than the more traditional ones.
2. To get away from the irritating detail which photography can so easily give.
3. To use reflected light, not as a softener to shadow, but as a subsidiary light.
4. The use of spot light.
5. To desire to avoid extreme sharpness in portraits, to portray more the mental likeness than the visual one.

Nathaniel Hawthorne, in 1858, records the remarkable story of a meeting with Browning in Florence. Browning spoke most rapturously of a portrait of Mrs. Browning which an Italian artist was painting for an American gentleman as a present to his wife. The success was perfect in two sittings. Browning had sat seventy-three times to an American painter. In the result every hair and speck was represented, yet this accumulation of minute truths did not, after all, amount to the true whole.

It was only an impression, yet Browning was more satisfied with this mental impression than with a visual one. When I chose my subject I had no idea that the Council would be so fortunate as to have a special lecture from Mr. Aylett on unusual light and soft focus.

Signore Bettini, of Rome, is an original worker. No photographs are just like his. Look at the lighting of these five portraits. Look at the light, the pose and background.

Signore Bonaventura, also from the Eternal City, works on different lines. He loves the mystery of shadow. He is one of Italy's forward workers.

Signore Socci is the principal of the house of Alinari, the house of technical excellence.

Here is a picture by the celebrated Vienna photographer, A. M. Scheim, and I also show some examples of the famous Berlin photographer, Nicola Perscheid. I here bear testimony to the unfailing courtesy with which all these gentlemen have acceded to my request to send me examples of their art.

Here is a most interesting subject—a lady taken with a portrait anastigmat lens and the same lady taken with a soft focus lens. Here is the celebrated Danish photographer, Peter Elfelt, of Copenhagen. Note the source of light and the background.

Now here is our old friend, who was at our last Congress and spoke so well, Ferdinand Flodin, of Stockholm, with all his warmth from a cold country. Now let me also show you some portraits by Dr. Goodwin. Those who saw Dr. Goodwin's show at the Royal last spring will not easily forget it. The work shows a great amount of versatility. Here is a head that has the classical spirit and would do credit to the Parthenon.

Now we come to Paris. No city shows more diversity of talent. Here let me say how all so willingly responded to my request for examples of their work. Here is the work of M. Benjamin. How strong it is! Here is the work of M. Meley; note its delicacy. Here is a charmingly posed picture by M. Manuel. Here are some celebrated people by M. Nadar, with a portrait of himself with a special message written on it. Here is the work of M. Reutlinger; how diverse they are, yet all good!

Now when I thought of this talk a couple of months ago I wrote to Mr. J. C. Abel, a power in the American photographic world, and asked if he could get me some examples of spot light and out-of-focus subjects. His response, like himself, was electric. His letter writing, even through the cold medium of ink, and still further cooled by the Atlantic thermometer, was warmth itself. It is a great disappointment not to have him here. He is a big-souled man; how he praised up our friend, Mr. Pirie Macdonald! I will not attempt more than simply to show you these; they illustrate some modern tendencies in portraiture.

The last picture I show you this evening is the portrait of Mr. A. H. Diehl, President of the American P.P.A. I invite you to stand as an indication of your warmth and brotherliness, not only as a token of respect to the gentleman himself, but to the large Society which he represents.

A. Swan Watson.

TRADE EXHIBITS AT THE CONGRESS.

The Akron Manufacturing Co. show specimens of their well-known dry-mounting presses and tissues. A special feature of the Akron press is the ball thrust which allows of easy movement of the pressure wheel. A new press, the "Akron Auxiliary," was demonstrated. This press has a new type of aluminium plate which is open all round, and will mount prints up to 15 × 12 on the ordinary plate-sunk mounts. The pressure is obtained by means of a compound lever acting on a flat spring. A 1,000-ft. roll of Akron dry-mounting tissue was also on view.

Messrs. Elliott & Sons, Ltd., made a special show of their new "Matt-Emulsion" plate. Negatives by prominent workers were arranged in cases illuminated by reflected light. Prints and enlargements from these negatives were upon the walls. The high quality of the enlargements clearly demonstrated the possibilities of the plate for this class of work. All prints and enlargements were upon "Verona," the Barnet warm black developing paper.

Messrs. Bartons' showed mounts and mounting papers in an unusually large and good variety. A new range of art boards were on view, in many surfaces and colours. Photo cases and folders were shown, especially appealing to the American market. Quadro frames were also prominent in brown, black, grey and gilt. This frame is inexpensive, and shows a high standard of artistic merit.

The old-established firm of S. H. Fry showed some exceedingly fine examples of trade enlarging. A wall panel was arranged with enlargements and prints of prominent personages.

The "Stipwell Retoucher" was a prominent feature at Messrs. Houghtons' stand. This retoucher is non-mechanical, and enables the worker to put his own personal control into the work. The "Stipwell" uses the ordinary pencil, to which a metal cap is affixed and attached to the end of a vibrating wire. The electrical vibrator is operated by a wet battery giving only 2½ volts. It is only necessary to guide the pencil over the work, the stipple effect being given by the vibrator. This prevents excessive exertion, and minimises retoucher's cramp. The price of the machine, viz., £5 complete, including battery and pencil, seems very reasonable for an efficient article. The upkeep of the Stipwell retoucher is said not to exceed 5s. per annum. The speed at which negative retouching by aid of this adjunct is possible, is very noticeable, the work in hand being completed in one-third of the usual time taken. Messrs. Houghtons, Ltd., were also showing an excellent range of mounts and albums, including the new architectural mount, and also a large display of dealers' utensils, demonstrating the wholesale capacity of the firm.

A new portrait paper was shown by Kappa Works, Ltd., and excellent prints, demonstrating the possibilities of this printing medium, were shown. Kappa is a developing paper with the speed of bromide, but the latitude of gaslight papers; no special developer is needed to obtain the warm, black tones; each worker using his own pet formula. This paper will be ready immediately after the Exhibition closes.

Kodak, Ltd., were showing portraits, by well-known professionals, on Kodak portrait film, and printed on "Etching Brown" paper. Film accessories and tanks were on view, and a well-made teak tank holding 18 half-plate or 16 1/1 plate films was shown. Visitors were recommended to call at Kodak House, Kingsway, where all the firm's specialties are being demonstrated.

Prints on Vitégas 7a cream and Vitégas Plat 12a were exhibited by Kosmos Photographics, Ltd. The latter paper has a true platinum effect, and the surface will take water colours. Novex plates were shown, and specimen negatives by prominent workers were on view. Prints upon the Kosmos collodion printing out paper were also shown.

At the stand of Peerless Photo Paper Co., Ltd., prints upon the special Peerless chloride paper were exhibited. This paper is eminently suitable for portraiture, the warm, black tone suiting the present-day style of work. The exhibited prints demonstrated the claim put forward by this firm in the direction of depth and luminosity of the shadows. Prints by a new colour process, in which no special alteration to camera or use of filters is necessary, were shown, the colour rendering being remarkable. This process has not yet been placed upon the market, but it is hoped soon to complete the necessary details.

The specialty of Mr. Dixon Scott's establishment is high-class enlarging and printing for the professional. Excellent specimens of this class of work were shown, and clearly demonstrated the personal attention which is given to all studio orders. Other departments catered for by this firm are commercial and ordinary developing and printing work.

Prominent amongst the exhibits of Wellington and Ward, Ltd., was the new "Q tone" paper and developer. The prints on this paper are of a beautiful warm black colour. The "Q tone" developer is now available for professional workers, being put up in cartons containing sufficient chemicals to make 84 ozs. of working strength developer. Prints and enlargements on all grades of Wellington papers were shown. A

separate stand was occupied with "Seltona" prints, and some fine results were shown, a large print showing the possibilities of double-toning by aid of a salt bath.

Mounts and albums were a specialty of Messrs. Witt and Westley's display. Hand-polished frames, of excellent quality and workmanship, were shown, the inlaid work being especially well done. Loose leaf albums, specimens of art boards and the "Weslem" dry mounting tissue were also on view. A notable feature of the stand was the panelled walls, with doors fitted, allowing the display of prints on three different surfaces.

Messrs. Chas. Zimmerman and Co. (Photographic), Ltd., showed specimen negatives on Agfa special fast studio plates, 500 H. and D. The possibilities of the Chromo Isolar plate were also demonstrated. The Isolar backing is between the film and the glass, and dissolves out in the developer. Agfa flash powder and lamps, and the one-solution mercuric intensifier were exhibited.

THE EXHIBITION OF THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

In order to print some notice of this exhibition before it closes, we have had to rely upon notes made in the turmoil and disorder of preparation, before the pictures could be identified with their authors in many cases. We saw enough, however, to speak quite confidently in general terms, although references to individual works, or groups of works, will be necessarily somewhat haphazard.

The pre-eminent impression of this show is of its importance and status. After all, the galleries of the Royal Institute of Painters are picture-galleries, and in that respect alone the move from Vincent Square is a circumstance which can claim congratulation. Piccadilly is the place for an exhibition that wishes to make an appeal to the public, whilst Vincent Square could never hope to attract visitors outside the trade. And it is to the outside public that the professional must first and last appeal. The visitor who is interested in the artistic advance of portrait photography will be more embarrassed than pleased with the dealers' stalls erected in the handsome large gallery, but then the exhibition is for the photographers as well as the photographed, and the former derive much help from the trade exhibits.

If only the public can be enticed, in fairly large numbers, to come and see, there can be no doubt that the Professional Photographers' Association will justify the plunge it has taken; if not in immediate profit on the venture, then certainly in the higher status it will gain for its work among people of taste and affluence.

As to the prints displayed there is not a great deal to choose between the exhibition and that of the London Salon, as far as portraiture pure and simple is concerned. For this year's P.P.A. display ranks practically as the Salon show, with a few professional show-cases emptied into it. This seems to argue that the professional's ground is firm, and that he has prospects. It has taken him a long time to come to the conclusion that success means artistic production; but now that he is working and spending money for that idea he may safely indulge in a little optimism. The struggle will be no less keen than of old, of course; but it will give brains and talent an equal chance with capitalised enterprise.

Another question that presents itself is whether this forward movement is likely to be strengthened or weakened by the inclusion of specimens that are not true portraiture. Aeroplane and other commercial photographs have their place, and landscapes may claim a modicum of ground in so far as it sometimes falls to the lot of a photographer to be asked for a view of a park or garden; but the ground is a narrow one. As to the nudes, must we assume that Mr. and Mrs. Park have a profitable clientèle for this genre? It seems to us that it would be expedient in future exhibitions to specialise with severe exclusiveness on likenesses of people's faces and clothed figures as they are likely to be wanted for ordinary purposes; always encouraging, of course, the utmost variety and resource upon legitimate lines. Theatrical work will be prolific enough in these directions, doubtless; but we have not yet got to the pitch of ideality seen in the Folies Bergères in the matter of the feminine *tout ensemble* to make the studies of Mr. and Mrs. Park, beautiful as they are, an adjunct even of theatrical portraiture.

One aim might be to show the resources of the studio equipment in the matter of settings, as G. M. Blake does, in the very happy arrangement of a lady in evening dress who stands in a panelled corner, with a window behind her. Another to show the ordinary sitter that beautiful prints are not necessarily due to beautiful faces, but necessarily to artistic insight of the photographer. People must be consistently taught—it will take years of course—to see the qualities in the treatment of such a head as that sent by Walter Scott, of a young man, which recalls all that is fine in great portraiture—simple lighting, strength of realisation, and personality, or the pictorial charm that mere garments can lend to a work when in good hands, as witness Chas. Borup's girl in a large hat and garments of delicious tones; likewise the furs in C. Wormold's print of a lady so clothed.

The room wherein these things hang is not too large for its purpose, and is beautifully lit. It includes excellent specimens from Lafayette, whose Mrs. Chas. Webb has a striking design, from R. N. Speaight, A. C. Banfield, Angus Basil, Estelle, W. F. Smart, Reginald Haines and others. There is not a single thing in this room that is below the standard of work at an exhibition in Russell Square or Pall Mall.

Other rooms are devoted to foreign countries. We have noted a series of small dark prints with light heads which are effective, but evidently a mannerism of their producer in Italy.

A truly German subject by F. Fiedler is that of a skeleton with its arm round the waist of a semi-nude woman. From Eugene Smith comes the surprise of a portrait of Sir Hy. Irving, seated.

The Dutch selection does not, on the whole, show any very distinctive work, whilst from France the print that pleases us most is a tinted transfer of a nicely posed and placed lady. The effect is very pleasing in this particular example, but others, treated in the same way, show how much of the style depends upon chance for real success. They are by G. L. Manuel Frères. The Swedish show is a good one, and the prints from America include well-known work from Pirie Macdonald and others.

Unfortunately the exhibition is only open for five days, the last being to-day, Friday.

F. C. Tilney.

Stafford Photographic Society.—This society has been re-formed under the presidency of Mr. Sydney T. Davies. Meetings are held every Monday at 5, Foregate Street, commencing at 8 p.m. The secretary is Mr. E. C. G. Webb, 17, Tithe Barn Road, Stafford.

Camera House Journal.—The September issue of Messrs. Butcher's house organ contains particulars of the latest introductions in the shape of home cinema and lantern outfits, and of enlarging lanterns.

PORTRAITURE AT THE LONDON SALON OF PHOTOGRAPHY.

It is probably due to the steady and persistent advance in facilities of all kinds that the general level of photographic prints made with a view to exhibition grows higher year by year. But it is just as evident a fact that the few extraordinarily good things do not get better and better every year; and this is proof that efficient apparatus and material gives everybody a chance, but, of itself, cannot secure the transcendant achievement. Apparatus and materials—largely fool-proof—are developed by the manufacturers to get certain effects, with the result that these various effects are pretty widely adopted, and soon reach the stage of the commonplace. Distinction becomes, therefore, more and more difficult on the technical side; it is, perhaps, only possible on the artistic side.

The general improvement in technique is a blessing in more ways than one; for besides raising the standard of work generally it has discouraged a little the idea that faking is a *sine qua non* of work that claims to be artistic. The Salon exhibition was never so free from faking of all kind, nor so full of beautiful prints "straightly" produced. Distinction to-day lies in the direction of fine design, character, lighting, and convincing realisation—things which cannot be got at the dealers. The struggle now is not for technics but for æsthetics.

On the art side of photographic portraiture there is illimitable room for improvement. A vast number of successful things are still the outcome of lucky chance, of some supreme effort that appears to be incapable of repetition. At any rate, there seems another theory to account for the fact that photographers rarely go consistently on from good to better. Out of an immense quantity of portraits at Pall Mall there are very few of which it can be said that their authors never did a better. But the truth also remains that in the generality there is a sounder, more genuine feeling for art abroad than there used to be.

Here and there one sees distinct evidence that the photographer has been inspired by some art method of expressing the charm of ordinary natural phenomena. The best instance of this is perhaps in "Pamela Smith" (40), by Marcus Adams, where the light and shade are obviously the theme of the design. The thing seems planned just as an eighteenth-century engraver would have planned it, for the beauty of the masses of light and shade as they are relieved upon an open background of sky, a mere strip of foreground affording something for the little maid to stand on. In such works we may assume that the technics of photography are a matter of course; but the art idea is a matter of choice and pursuit. This, by the way, is an entirely different thing from the mere unfeeling mimicry of art methods and media; nor do we imply that artistic photography cannot break its own new ground in the search for beauty that the old art methods could never have arrived at. But the latter kind will belong to the technics of photography rather than to the bulb-presser himself, who can hardly be expected to find new principles of beauty unknown to the artists of the past.

Those who prepare exhibitions have to consider factors which would have no weight in a studio. The whole show has to present a striking and attractive appearance, and this means that large prints get preferential treatment, and a decided look-out is kept for any that "stand out" when on the wall—a qualification which usually boils down to a boldly-marked "pattern" and clean cut relief of light and shade. It is in reality these qualities that we admire in Yvonne Park's "La Boheme" (11), Herbert Lambert's "Dame Ethel Smyth" (96) or H. v. Wadenoyen's "Miss Una O'Connor" (120). In the case of the first and last, the subtle beauty of the faces is scarcely noticed, much less enjoyed, until one has broken away from the masses of black in which they are buried. One certainly cannot see, properly, both these respective parts at the same distance and with the same visual adjustment.

May it not be questioned whether this kind of selection is of any advantage except to "the Gate"? Does it not encourage the manufacture of great, strong, prints that would be almost insufferable on the walls of modern houses? At the Salon the small and delicate things that do happen to be selected are usually placed upon the screens, where they get neither their fair share of light nor attention. There is no denying that the R.W.S. Gallery presents a very distinguished appearance as hung by the London Salon officials, but the fact remains that it is not the best friend to the kind of print that professional photographers sell most of. The worthy officials would perhaps reply that their show is for the amateur pictorialist, but as a matter of fact the visitor will find the exhibits nearly all portraiture, and where the portraits are not by recognised professionals, they are by the amateurs who are graduating for the profession.

The amateur, or the chrysalid professional, as the case may be, nevertheless takes a front-rank place. The names of Mesdames D and R Morter are new to us, and we must assume that as their leading work here is also shown at the P.P.A. exhibition at the R.I., they are not amateurs. In any case, we are glad to congratulate them upon two remarkably successful works. The first is "Master of the Hounds" (2), a lady, in the dress of the chase, and holding a crop in both hands. The pose is very spontaneous, natural and quiet, yet by no means ordinary. A little rakishness is given by the tilt of the hat over one eye. The other work is called "Altum Silentium" (70), and depicts a woman under stress of high and silent emotion, expressed not only in the tenseness of the facial muscles but in the rigidity of the arms and wrists. Both these prints are of admirable quality, and of the kind that is not best appreciated from the opposite side of the room.

Another worker who comes to the front this year is Lionel Wood. He sends a most engaging portrait of a young girl with an expression that is spontaneous and instantaneous—two qualities that were ever sought for by the masters of old and only secured by the very best of them. Here is a matter in which photography has broken new ground, but has not given it much intensive culture. The work by Mr. Wood is "Miss Hawthorne Wood" (23), whose parted lips will win for her many admirers. Charles Borup seems to have asserted himself also. His best works are "Mrs. Thomas Foster" (238) and "Molly Mortimer" (279), a very charming little girl cuddling a cat. We understand that it is a portrait of Mr. F. J. Mortimer's daughter. The other work is perhaps more original, and though very flat in its modelling, it is a most attractive print, and possibly one of which the style would prove popular for the kind of subject dealt with. Perhaps we should also include among the few who have reached their high-water mark in this show the name of Yevonde, who has had the discernment to adopt a formal and deliberately simple treatment for the style of sitter shown in "Eleanor Alderson-Smith" (223). The lady has clear, sybil-like eyes that are deep, calm, and steady in their gaze; her hair is smooth and symmetrically dressed, the lines of her face pure and classic. Yevonde has fittingly placed her before us at full-face, and has not permitted any trace of "expression" to mar the static formality of the effect. We wish she had extended this wise choice to the restless background.

After two or three years of portraiture of the dramatic or

A sheet of drawings found within the last few days between Pall Mall East and the Princes Galleries, Piccadilly, has come into our possession. We cannot think with what object the artist has made what appear to be perverted versions of notable works of pictorial photography, but at the risk of infringing his copyright, and thinking that perhaps others may like to share the irresponsible fun which appears to have been his only motive, we have reproduced his sheet exactly as it is.

dynamic kind, it is agreeable to find that there is a tendency now towards the simple in pose and effect, and that where there is a subject of smooth, strong lines and pure form the influence upon the photographer has not been lost. Examples of this feeling for classic form are seen in C. Scarabello's "Irene" (184), a beautiful head and bust, on which the very folds of the garment recall the qualities of sculpture; in Louis Fleckenstein's "Cecilia" (168), a native of some sort, but a representation nevertheless on the classic lines of largeness of style and generalisation, with a perfect gradation of light over all; and in "A Girl's Head" (283), by N. Sviatscheff. The nobility of style that characterises this class of work relies, it will be seen, upon the realisation of roundness and the play of light under a simple scheme of illumination. The modelling will be full, the light and shade well contrasted, and the forms severe, without those other charms of elaboration, intricacy, ornaments, sparkle, variety of texture, and surrounding incident.

In the opposite direction we have works like Yvonne Park's "Queen Elizabeth—impersonated by Miss Laura Cowie" (84), which is simply a mass of elaborate forms and glitter; the two red prints by A. F. Kales, "Margaret de la Motte" (109) and "Portrait in Red Chalk" (115), neither of which are more than touchy kind of sketches, with no suggestion of roundness; Charles Taylor's "L'Apache" (128), an absolute complexity; even the charming "Ann Forest" (135), which is all but a silhouette; or the very effective "Sheila" (263), a front-face head in a circle by Monte Luke.

We have remarked that the workers from whom, in the past, we have had pictures that touched the top degree of current work have not in this collection surpassed their former efforts. Let it not be thought, however, that they have fallen appreciably below the standard expected of them. Herbert Lambert's "Stephen" (29), a handsome youth in a "sweater," is a fine piece of work of that kind that is an ornament in a gallery or an immense dining-room; it would be a little overpowering in a small room. Pirie Macdonald's "J. Leeming Walker" (57) we have already admired at Russell Square. Its great characteristics are the smile and the monocle. A. Keith Dannatt sends more of his psychological essays in unhappy humanity. "Portrait Study" (123) is a picture of anxiety and trouble, and, like his "Etaples Types" (53), is a presentment unredeemed by the pathos he gave us last year in these studies. The large print sent by C. Pollard Crowther, "Russell Thorndike as Peer Gynt" (174), misses nothing of that skill Mr. Crowther displays in getting the last ounce out of his model, but in this case the work has been flattened by the dark all-over tint in which the subject is submerged. W. Crooke's "H. S. Gamley, R.S.A." (240), is at that standard of efficiency beyond which it seems impossible for Mr. Crooke to advance. The same may be said for H. Vandyk's "Bourgamestre Max" (261).

"Joseph Pennell" (408), by R. T. Dooner, arrested our notice at Westminster recently, and we are glad that it has found a place here, for it is a splendid example of an harmonious scheme of tones, besides being an exquisite piece of portraiture. The Earl of Carnarvon, in "Portrait" (293), though not, perhaps, surpassing himself, gives us a clever and delightful picture of a lady with a gleaming headdress and her face in shadow, a work which will certainly confirm his reputation.

We may venture a word or two of criticism upon a print or two well worthy of examination. What a pity that P. Chaumoff allowed the hard, black contour of the back of "Rodin" (13) to come in at all! The figure would have been much better placed if the trimming knife had cut right through the sculptor's figure. Would it not have improved H. v. Wadenoyen's "J. Brandon Thomas" (54) if it had been smaller in scale for the paper, and thus truncated fewer of the forms? And could not L. Fleckenstein's admirable "Louise Vandahof" (45) have been a little less yellow?

A strong exhibitor of pre-war days has returned to the arena, and we are glad to welcome Furley Lewis, with his "John Galsworthy, Esq." (43), a work that is replete with the style and charm of old. Another reappearance is that of Reginald Craigie, who once held the tiller of this ship of rebels when it adventured on waters uncharted by the R.P.S. He exhibits "A Portrait" (277) of a gentleman, in profile.

We cannot in fairness to high merit leave this review without recommending to the visitor's notice the following few works: "Joan—daughter of Julius Harrison" (119), by Herbert Lambert, for the delightful torsion of the little maid's pose; "J. Craig Annan, Esq." (155), by N. E. Luboshez, for its marvellous rightness everywhere—the poetry of the ordinary (this applies to the sitter's clothes, not to his personality); and the same worker's "Portrait" (183), whose "bright smile haunts us still"; another smiler, a brigand, by Mrs. Ambrose Ralli, for its masterful management of white and black, called "At Corinth" (209); Rd. N. Speaight's "Study of a Child" (256), for its object-lesson in harmony of line, "The Rt. Hon. Viscount Grey" (267), by E. D. Young, for its convincing vitality and three-dimensional merits, and "The Poacher" (291), by G. H. High, for its admirable spacing.

To speak of more would simply be to extend this notice into a mere catalogue of things all remarkable for some quality or other.

F. C. TILNEY.

FORTHCOMING EXHIBITIONS.

September 9 to October 7.—London Salon of Photography. Particulars from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 11 to 15.—Professional Photographers' Association, Prince's Galleries, Piccadilly, London, W. (Trade and Professional). Hon. Secretary, Richard N. Speaight, 157, New Bond Street, London, W.1. Also foreign invitation loan exhibition of professional portraiture. Hon. Secretary, Marcus Adams, 43, Dover Street, London, W.1.

September 18 to October 28.—Royal Photographic Society Annual Exhibition. Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

October 18 to 21.—Rotherham Photographic Society. Latest date for entries October 4. Hon. Secretary, S. G. Liversidge, Orissa, Gerard Road, Rotherham.

October 18 to 28.—Portsmouth Camera Club. Latest dates: Entry forms, October 11; exhibits, October 16. Particulars from the Hon. Secretary, C. C. Davies, 25, Stubbington Avenue, North End, Portsmouth.

1923.

March 2 to 31.—Pittsburgh Salon of Photography. Latest date, February 5. Secretary, Charles K. Archer, 1,412, Carnegie Building, Pittsburgh, Pa., U.S.A.

March 13 to 16.—Exeter and West of England Photographic Exhibition. Particulars from the Hon. Secretary, Frederic G. Tutton, 9, Union Road, Pennsylvania, Exeter.

THE FREE SITTING.—The way in which members of the public regard the system of offering sittings (and portraits) for nothing, is shown by the following paragraph by the London correspondent of the "Glasgow Herald." He writes:— "I have just met an author on his way from Bond Street, where he had been graciously "giving a sitting" for "camera studies" to a well-known firm of photographers. The request that he should do so, he tells me, reaches him from one or other of the big photographers every year—and has done so for the past 20 years and more. Yet he is not a popular novelist, and his countenance has not appeared in the press above three or four times in all those years. He suggests that the photographers must work their way through some popular book of reference during the slack seasons, and that without any nice discrimination as to the popularity of those whom they invite to be taken."

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

THE NEW PRESIDENT.

By the election to the presidency of Mr. Alexander Corbett, the Professional Photographers' Association honours one who has been connected with it from the day of its establishment, and throughout the twenty-one years of its existence has been one of its heartiest supporters. Mr. Corbett began his career as a professional photographer thirty years ago with Mr. Alfred Ellis (Ellis and Walery) in Baker Street, and during his early days in that firm was one of the pioneers in studio portraiture by artificial light. Some years ago he established a studio of his own in Orchard Street on the site which is now occupied by the extension of Messrs. Selfridge's building. It was a very fortunate choice for a new business, since the entrance way (which was all the display which Mr. Corbett could obtain) was sandwiched between two large

Portrait by Richard N. Speaight.

MR. ALEXANDER CORBETT,
President Professional Photographers' Association, 1922-23.

drapers' shops, so that the constant procession of feminine shoppers automatically had the portraiture of Mr. Corbett brought in front of their noses. Portraits of many notable society people, among them H.R.H. The Princess Royal, brought Mr. Corbett into further notice as a photographer of talent, and thus on being compelled to find new premises for his business within a comparatively short time of its establishment he was able to transfer it with success to the present premises about midway along Baker Street, where his studios contain a very modern equipment of electric light by which a great deal of his work is done.

Mr. Corbett has been a member of the Council of the P.P.A. since 1911, and may perhaps be described as one of its most independent members, since in several matters he has emphatically dissented from the opinions of the majority. Unlike many photographers in the West-end of London, he has always set his face against the practice of the indiscriminate offer of free sittings. With scarcely an exception, all the portraiture in his business is commissioned by the customer; and it is worth while to refer to this fact, because it shows that this policy is not inconsistent with a considerable revenue, by arrangement with the sitters, in the shape of reproduction fees from the newspapers.

Mr. Corbett takes a strong interest in the local affairs of the district of London in which his business is carried on, and for the past three years has been a member of the Marylebone Borough Council. The new President of the P.P.A. is thus one of its oldest members who unites in himself a long and successful career, artistically and professionally. He has devoted himself to his art, and, in answer to our question, had to admit that his only recreation was—photography. Members of the P.P.A. may depend with confidence that his election is a wise choice of president to continue the forward movement in the P.P.A. which the last twelve months have marked.

"HARD" AND "SOFT" PLATES.

SOME little time ago a good deal was said and written about "grades" of development papers. For some years past the majority of photographers have taken a sort of "take it for granted" attitude that bromide paper was soft, and gaslight paper was hard or contrasty. That both makes included both grades was not generally admitted. As a matter of fact, most bromide paper was rather soft at one time, but some makes were more contrasty than others For some time now, however, it has been possible to get the same make in a number of grades, while the two or three grades of gaslight paper are, or should be, well known. A number of articles and some controversy on the subject were calculated to clear up any doubt on a most important point, but even now one hears experienced hands referring to negatives that are suitable to bromide and others that require gaslight, observations that are quite meaningless. And even manufacturers advertise papers in "grades" of "rough," "smooth," "glossy," etc., a practice which leaves us in doubt as to what a "grade" really is after all.

A particular make of bromide paper can be had in any surface in a series of grades ranging from soft to exceptionally hard. As the grade titles suggest, these papers will deal with a series of widely different negatives, ranging from the hardest to the flattest. While this may encourage slackness in negative making, it is nevertheless a boon to the man who has to deal with other people's negatives, and the use of a series of grades, or even two grades, explains the fundamentals of soft and contrasty emulsions better than any number of words can.

A definite choice of grades, always a feature of gaslight paper, more recently applicable to bromides, is now possible with plates. A soft grade of their Eclipse plate has been marketed by the Imperial Co.

The demand for soft plates is parallel to that for hard and soft papers, but the two cases are not exactly parallel in every way. One can get hard or soft results from any plate emulsion by careful handling; the same does not apply to papers. And the speed of a plate very often indicates the most likely character of a negative made by normal treatment. There may or may not be scientific reasons for this, but in practice it is generally so. Therefore it would seem the grades of plates are not so necessary. But there is scope for a plate which will readily give one a fairly definite contrast without undue deliberation in handling, and regardless of speed. This is evidenced by amateurs' films, which are—by reason of standard development—at the mercy of the manufacturer as to contrast. Negatives taken on X's British film are different altogether to others taken under identical conditions on Z's American or Y's German spools. This means that the amateur who does his own printing, and believes in one kind of paper, must stick to one make of film to avoid trouble. I remember a case that happened with a professional friend who was fond of soft bromide paper and would not try anything else. It was in the early days of the R.S. Lightning Plate. He took up this plate on account of its speed, but could never get bright prints from the negatives. I advised him to develop them longer—the negatives—but as he used a dish and was naturally careless about light, this resulted more in fog than anything else. So I advised getting a more brilliant paper, but that he would not do. Then I said that it would be as well to go back to the R.S. Rapids which he had been using before, and on which he always got contrasty negatives. He did so, with the desired results, but had to sacrifice speed This was no fault of the fast plate; it was merely that it *readily* gave soft negatives, and my friend was more adapted to use something that *readily* gave hard negatives. There were no grades then.

To be able to use a plate that is addicted to giving a certain result, and will not give the opposite with deliberate handling, and to do that without using a speed which may or may not be

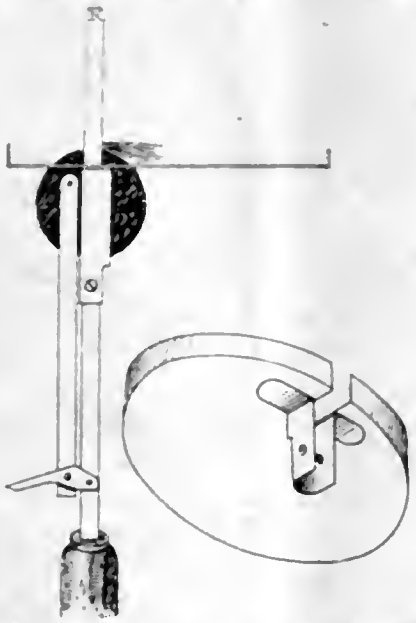
right is yet another power put into the photographer's hands. A fast plate which can be obtained in soft or ordinary grades is attractive. For example, indoor portraiture, especially when the wall paper is dark or the sunshine is getting in, is apt to produce harsh negatives no matter how careful we are. A decidedly soft plate is useful here. The same case arises with commercial work, for control of the light in machine shops and buildings is impossible as a rule, and it is as likely to be harsh or not. In fact, with any exposure, the scene may warrant a decidedly soft or hard emulsion, just as any negative may warrant a decidedly hard of soft paper; with this difference, of course, that plate emulsions have greater latitude than the others, and a plate can be developed to any one of a large number of "gammas" without spoiling it as a negative. The beauty of the choice of emulsions in this case lies in the predetermined character of the negative, which will be hard or soft according to the grade used—unless definite steps are taken to prevent it.—TIDERMIT.

Assistants' Notes.

Notes by and for assistants will be considered for this column. Payment for accepted contributions is made on the first of the month following publication.

A Flash-Lamp Igniter.

MUCH has been written, and many types of apparatus invented, with the idea of helping the professional as well as the amateur in flashlight photography. There is no doubt, however, that complete success depends largely upon the efficiency of the flash-lamp used and its ability to work each and every time it is called upon to do so. At the present time a large number of automatic gaslighters are appearing on the market, some of them being very efficient, with little or no mechanism to get out of order. One of these instruments, costing only sixpence, has been



adapted as a flashlamp igniter, and has proved an eminent success. To turn this lighter into an efficient flashlamp requires but little mechanical skill, but should it be found necessary, a tinsmith would make the required adjustments at a very small charge.

First obtain a cocoa-tin lid of about 3 or 4 inches diameter, and with a pair of scissors cut out a strip along the diameter nearly one inch long and a quarter of an inch wide. Now take a thin strip of tin or brass 2 inches by 1¼ inches, and bend it along its length, making a groove of U-section sufficiently wide to allow the lighter to rest in it comfortably. The groove is now cut down about 1¼ inches and opened out, making a double bracket, as shown in the illustration. This bracket is now soldered to the tin lid, the open end corresponding with the piece cut out. The whole arrangement is then fitted to the gaslighter, and adjusted so that the sparks from the lighter are level with the lid. A small hole is now drilled through both bracket and lighter, and through this a screw with a nut on the end is inserted. This will keep the flashpan firmly fixed in position. It can now be readily seen that the finished article is easily held above the head of the operator and the camera, and sparks continuously let off with very little trouble, an important asset in flashlight photography. As in all flashlamps, it is advisable to heap the flash powder near the source of ignition, this being the only precaution necessary to render the lamp successful in its working. The total cost of this instrument need not exceed 1s. 6d.—S. C. GORDON.

A Levelled Draining-Board.

IN fitting up a dark-room it is frequently considered essential to give considerable space to sinks. Unless a good deal of large-sized work is to be handled, and neither space or cost is of great moment, this can be easily overdone. A draining-board of ample area, provided it really drains into the sink and not on to the floor, is less costly than a large sink, and more comfortable to work upon. Developing, toning, and so on, can be done just as well upon the board by the simple expedient of screwing on it lengthwise strips of wood about an inch thick, and tapered to the same slope as the draining-board, but reversed so as to produce a level top, while spilt liquid runs away underneath. Such a board is quickly washed down and mopped dry when it serves as a bench for many purposes.—D. C.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications August 28 to September 2:—

FILMS. No. 23,360. Photographic films. Gevaert Photo-Producten N.V.

APPARATUS. No. 23,524. Apparatus for development, fixing, washing, etc., of photographic films, etc. C. H. Kruger.

PRINTING. No. 23,816. Photographic printing devices. B. Wehrli.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

HOODS FOR CAMERAS.—No. 183,626 (May 13, 1921). According to the present invention there is a collapsible hood having a flap hinged at or near to the outer end, such flap being fitted with a lens, so that when the hood is in position on the camera, the flap can be arranged to permit the image on the focussing screen to be viewed through the lens, and when the hood is removed from the camera, the flap can be turned about its hinge into or within the hood to allow the hood to be collapsed into a flattened form.

The hood may have a portion of substantially rectangular cross section for fitting on to or into the existing focussing hood of the camera and a tapered portion extending rearwardly therefrom, at or near to the end of which tapered portion, the flap, fitted with the lens, is hinged.

A hood, constructed in accordance with the invention, is shown in the accompanying drawings, in which fig. 1 is a perspective view of the hood in the open position; fig. 2 is a perspective view of the hood in the closed or folded position; fig. 3 is a longitudinal cross section of the hood in the open position; figs. 4 and 5 are end elevations of the hood, in the open and partly folded or closed positions respectively; and fig. 6 is a diagrammatic view of the hood applied to the existing hood of a camera.

In carrying out the invention according to one mode by way of example, as shown in the drawings, an open-ended hood 1 of rectangular cross section, tapering from a point 2 a suitable distance from one end 3, to the opposite end 4, is provided with collapsible or foldable side walls 5. The top 6 and bottom 7

of the hood may be constructed of pasteboard, cardboard, millboard, or any suitable material, and the side walls 5 may be made collapsible or foldable by constructing them of flexible material such as leather or linen, or they may be formed of comparatively rigid material such as pasteboard, cardboard, etc., and each divided along the horizontal centre line into two parts, and the parts hinged together.

It is advisable, when the side walls are constructed of flexible material, to form a permanent crease 8 along the horizontal

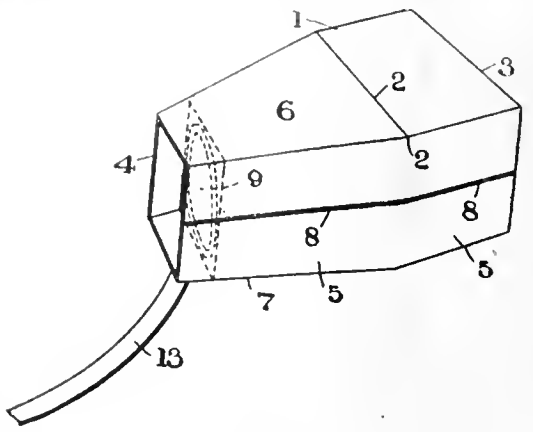


Fig. 1.

centre lines to ensure neat folding without crumpling or wrinkling of the walls. A rectangular flap 9 provided at the middle with a suitable lens 10, is transversely disposed within the tapered end 4 of the hood 1 and is hinged at its upper edge 11 to the top of the hood.

A convenient method of mounting the lens 10 in the flap is to arrange it in the opening between two circular frames 12 riveted

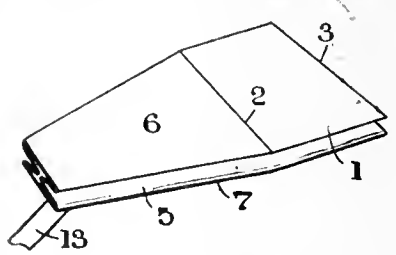

Fig. 2.

one on each side of the flap. The depth and width of the flap correspond with the internal depth and width of the hood at the point at which the flap 9 is fitted, so that when in the vertical position it closes the hood at the tapered end.

A tab, ribbon, or cord 13 is connected to the lower edge of the flap, and is passed through a slot or hole 14 formed in the bottom 7 of the hood. The flap is hinged to the top of the hood

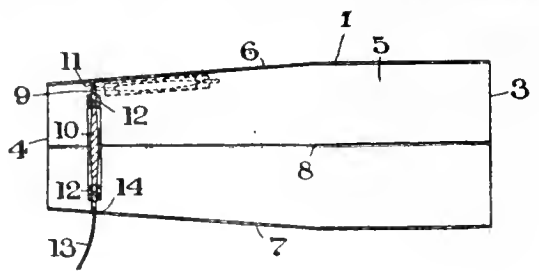

Fig. 3.

at a point a short distance in from the outer extremity of the tapered end 4, but, if desired, may be hinged at each extremity.

In use, the hood is opened out and the larger end 3 is fitted into, or, as shown in fig. 6, on to, the existing focussing hood 15 of the camera 16, the ribbon or string 13 being pulled to draw the flap 9 into a vertical position, so that it closes the tapered end of the hood, as illustrated in that figure. The larger end 3 of the hood should fit fairly tightly in or on the existing hood 15, to enable the one to be held in position in or on the other.

The operator can now view the image on the focussing screen,

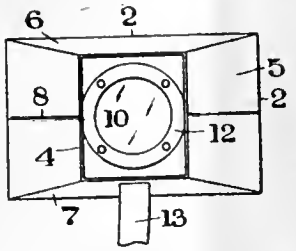

Fig. 4.

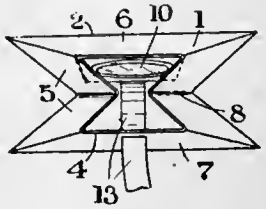

Fig. 5.

through the lens in the flap 9, thus enabling him to compose his picture and to carry out the focussing operations.

When not required for use, the hood is removed from the camera and the top and bottom are pressed together, whereupon the side walls collapse or fold inwardly towards one another along the horizontal centre lines, the hinged flap moving upwardly into

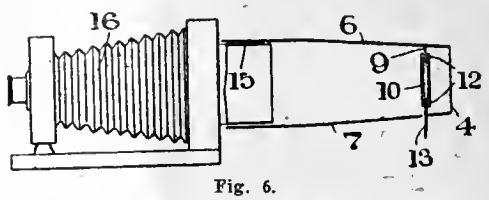

Fig. 6.

a horizontal position, indicated in dotted lines in fig. 3, so that the hood finally assumes a compact flattened form as shown in fig. 2, convenient for carrying in the pocket.—Thomas Peacock and Newman and Guardia, Ltd., 17 and 18, Rathbone Place, London, W.

The following complete specificatione are open to public inspection before acceptance :—

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

THE KEY TO SUCCESS (BULLDOG-WORLD DESIGN).—No. B425,574. Photographic papers. Kappa Works, Ltd., Mogden Lane, Isleworth, Middlesex, baryters and manufacturers of photographic papers. April 27, 1922.

GLASGOW AND WEST OF SCOTLAND SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.—Although there is, as a rule, a lull during the summer months in the activities of photographic societies, this society is very active just now in carrying out the necessary arrangements for holding a photographic exhibition. The McLellan galleries have been engaged for the event for the week commencing October 2, 1922, and there has been a ready response by professional photographers in the City for space at the exhibition. The Lord Provost of Glasgow has consented formally to open it on Monday, October 2, and it is anticipated that there will be a large and interested gathering on the occasion. Tea will be supplied, and the comfort of friends present attended to in other directions. Mr. C. Pollard Crowther, F.R.P.S., of London, is also expected to be present at the opening, and has kindly consented to deliver addresses on certain evenings during the week. The exhibition arrangements are in the hands of a sub-committee consisting of Messrs. J. R. Brinkley (President), Archibald Fairbairn, Q. R. Whyte, J. G. Mainds, R. Shankland, and the Secretary of the Society, W. A. Callander, Solicitor, 100, West Regent Street, Glasgow.

New Materials.

IMPERIAL ROLL FILM.—That a film bearing the name of the Imperial Dry Plate Company should be of the highest quality is a proposition that scarcely calls for proof or confirmation. The numerous users of Imperial plates in all parts of the world will at once assume that an Imperial film is of the best, and they will not be disappointed. Nevertheless, we have taken the opportunity to expose a few of the spools, kindly sent to us by the Imperial Company, and under the ordinary conditions of exposure in a cheap film camera, obtained negatives which left nothing to be desired. The film is wound on an all-metal spool, and each spool is wrapped in a waterproof paper before insertion in the green cartons, which give a distinctive appearance to the product in the dealer's window. For development the Imperial pyro-soda formula is recommended, the films developing readily and obtaining good vigour and contrast in about three minutes. Spools are supplied in a range of 17 sizes, from 4 x 5 cm. up to postcard. From the long list of cameras, spools for which are supplied, there must be very few film cameras on the market which cannot now be fitted with Imperial film.

BORAX M.-Q. DEVELOPER.—This type of developer for obtaining warm black tones on bromide paper is growing in popularity, the prints obtained by its use being most pleasing in colour. Under the title of "Q tone" developer, Messrs. Wellington & Ward, Ltd., have placed upon the market a carton containing sufficient chemicals for compounding 80 ozs. of the developer ready for use. The chemicals are contained in two packets, a glass tube, and a paper bag. The contents of these are to be dissolved in 40 ozs. of warm water each; the solutions are then mixed together and the developer is ready for use. It can, however, be diluted with an equal volume of water before use if required. The developer is recommended for use with all grades of Wellington papers, including S.C.P. (Gaslight) B.B. and the special "Q tone" paper. We have recently had the opportunity of testing this developer, and find that fine warm black tones are obtained on most makes of bromide papers, the best results, however are obtained on Wellington "Q tone" paper. The carton containing sufficient chemicals, to make 80 ozs. of solution is retailed at 2s.

FRAMES FOR PORTRAITS.—We have recently had the pleasure of looking at many of the patterns of frames and mouldings therefor made by the Bernard Manufacturing Co., 115, Victoria Street, Westminster, London, S.W.1. The Bernard Co. has been fortunate in combining within its management long experience in the making of artistic wood mouldings and a knowledge of the styles and types of moulding which commend themselves to portrait photographers of reputation. The result is that the goods which they supply can be most emphatically recommended to the notice of photographic studios. They comprise a very great variety. Among them are gilt mouldings from the largest, suitable for large portraits in oils, to the narrow reeds appropriate to prints of quite moderate size. Their range of mouldings in fumed oak is equally large, but perhaps the most attractive and original of these uniformly tasteful goods are the mouldings of antique pattern and colour in gilt and the series of similar smaller mouldings in imitation art metal and wood. To select only one or two actual specimens from a large number, Nos. 5,285, 6,322, 4,663 and 3,896, will especially please those who wish to offer their customers distinctive frames of the beautiful colour and designs, such as were used in the eighteenth century. A more modern note is struck by No. 362 in gilt, silver or copper, whilst among the wood frames No. 5,274, of tortoiseshell pattern, is exceedingly pleasing. The Bernard Co. offer to send for 1s. (the cost of carriage) a set of about three dozen specimens of moulding, mounted on a stout board for hanging on the wall, and representing many times this number of mouldings differing from the specimens in size, colour, etc. Also the company makes a special feature of supplying frames in any size whatever. They have no stock sizes, but will supply frames of any size, complete with glass and backs, precisely at the listed prices of the mouldings. Thus the photographer has simply to measure up the length of moulding required in a frame of the size he wants, multiply by the number of frames, and can then quickly calculate the cost from the Bernard Co.'s list. Goods are sent by the company carriage paid. As regards the frames themselves, we should refer to their exceedingly good workmanship and finish. Special attention has been given to the fitting and polishing of the backs, which in some patterns are of wood and in others of card, and to the strength and neatness of the mitring. With these various points of quality and service to their credit, including dispatch of goods within a day of receipt of order, we are not surprised to hear that the Bernard Co. have rapidly obtained on their books the names of leading professional photographers throughout the United Kingdom.

New Apparatus.

The Focuslite Spotlight. Made by Cinema Traders, Ltd., 26, Church Street, Soho, London, W.1.

THIS lighting accessory for the portrait studio consists of a substantially made metal lamp body, containing a high-power lamp, mounted behind a condenser, and in the rear of which is fitted an optically ground mangin mirror reflector. This reflector so increases the power of the light that approximately 4 candle-power per watt is obtained. The lamp and reflector are adjusted by means of clamping screws, thus allowing a perfectly central light source to be obtained. The lamp body is supported in a U-shaped frame,

which enables the light to be swung up or down through a large angle and therefore directed to any part of the studio. The stand is also swivelling, thus allowing lateral adjustments to be made. By an ingenious device it is possible to project a beam of light of any size, from a few inches to 20 ft. in diameter, by simply sliding a knob fitted under the lantern which moves the lamp and reflector backward and forward. This is a great advantage, as a direct spot or flood of light can be used as desired.

The Focuslite is as useful in the daylight studio as it is in the one where artificial lighting is used, since it is a great aid to daylight for illuminating dark corners, portions of dress, etc. Rembrandt like effects can easily be obtained by placing this lamp in the correct position to illuminate the sitter.

A special matt screen is supplied to fit in front of the lantern for diffusing and a tinted screen, also supplied, tones down the beam to approximate daylight. Amongst the special uses of this lamp in studio work is the production of firelight studies, for which the lantern is placed near the floor, while for spot illumination and backlighting it is invaluable. The lamp can also be used for illuminating articles for copying, as with the diffusing screen in position, a perfectly even lighting is obtained.

The lamp is mounted upon a strong, well made stand, running on casters, and is thus available for instant removal to any part of the studio. The apparatus is easily packed for transport if necessary, and for use is connected by a plug to the ordinary house lighting circuit. No resistance or alterations in the wiring or fittings are necessary.

The Focuslite Spotlight is supplied in two sizes, viz., 1,000 candle-power and 1,500 candle power, the price of the first being £8 15s. and of the second £9 5s. These prices include everything necessary for immediate use. We have had an opportunity of seeing this lamp in operation, and have no hesitation in recommending it for general studio use to our readers.

£3,000 COMPETITION.—The organisers of the competition in which £3,000 is being awarded for photographs made on dry-plates have issued a *de luxe* booklet of excellent reproductions in photogravure of photographs which received awards in the first part of the competition. The booklet shows the interest and artistic quality which characterised the work to which prizes have been awarded. In connection with the second part of the competition, closing at the end of the present year, a booklet has also been published describing the simple equipment which is sufficient for taking part in the competition and giving some hints on the profit which may come to those who take up photography under this stimulus. Both booklets may be obtained on application to the headquarters of the competition, 4, Oxford Street, London, W.1.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, SEPTEMBER 18.

Southampton C.C. Demonstration and Exhibition of Colour Photography.

TUESDAY, SEPTEMBER 19.

Bournemouth C.C. "Some Experiments with Desensitol and Colour Sensitiveness of Plates." W. Dieselhurst.
Hackney Phot. Soc. Canterbury Cathedral. S. D. Miller.
Manchester Amateur P.S. Exhibition of the "Amateur Photographer and Photography" Prize Prints.

WEDNESDAY, SEPTEMBER 20.

Bradford P.S. Outing. Visit to Birkshall Gas Works (Laisterdyke).
Dennistoun Amateur P.A. Final Stages of Winter Syllabus.
Exeter Camera Club. Outing to Bystock.
Rochdale Amateur P.S. Exhibition in Studio of Members' Prints from Rambles.

THURSDAY, SEPTEMBER 21.

The Royal Photographic Society (Pictorial Group). "Sunlight and Other Matters." Hugo van Wadenoyen, F.R.P.S.
Hackney Phot. Soc. Ickenham to Denham.

SATURDAY, SEPTEMBER 23.

Hackney Phot. Soc. City Outing. H. E. Wood.
Rochdale Amateur Phot. Soc. Outing to Ealees and Hollingworth.
South Glasgow C.C. Outing to Callander.
Willesden Phot. Soc. Outing to Bankside.

CROYDON CAMERA CLUB.

Mr. J. W. Walker read a short paper on the "Marion Record Iso Plate," to which he has recently been giving a thorough test for varied out-of-door work.

Braced by an unrivalled reputation for disaster, the lecturer should have courted and experienced nothing but failure. Nevertheless, excepting early errors due to over-exposure, success was attained, judging by the many excellent prints shown from negatives made on this ultra-fast brand, primarily designed for portraiture in the studio.

The rapidity of the Record plate, he said, is almost beyond belief, and in case of doubt it is always safer to halve the estimated exposure than to double it, as is the practice with some workers with plates of moderate speed.

Very little latitude existed in the direction of over-exposure, whilst the contrary prevailed with under-exposure. In fact, it seemed difficult to under-expose Record plates, and extremely easy to ruin the negative with even moderate over-exposure.

On an average out-of-door subject in diffused summer light, 1-140th sec. at f/6.8 with a K1 filter in use gave ample light-action, the filter increasing exposure about twice. For a narrow street scene, 1-100th sec. at f/8, without filter, would be found about right. These speeds were actual, not reputed.

Among his friends, all who had used the plate for portraiture and interior work had praised it highly; others who had employed it for landscape work were not invariably enthusiastic, a general complaint being the inability to secure sufficient density. He had also experienced this occasionally, Naturally, with a plate of such extreme speed it was not all jam, and from start to finish great care in all manipulations had to be exercised. The Record plate undoubtedly put a new power in the hands of the photographer, and rendered a tripod superfluous in outdoor work.

In the discussion Mr. Harpur said the Record plate was the fastest plate he had dropped upon "so far as related to exposure," and he was now using it for landscape work. Mr. Salt hoped any beginners present would not follow Mr. Harpur's example. Plates of such extreme speed were invaluable for special purposes, but in the majority of cases photographers needlessly handicapped themselves by using them.

Mr. Hibbert pointed out that lack of density was often due to insufficient development, which with these plates frequently had to be prolonged. He recommended a little bromide in the developer. In answer to questions, Mr. Walker said granularity in the negative appeared pronounced, but was not observable in contact prints and hardly apparent in enlargements. In cases of known over-exposure it was often possible to save the negative by adding to every ounce of developer 30 or 40 drops of bromide. "Any particular strength?" gently inquired a member. "Ten per cent.," answered Mr Walker, adding a pleasing reference to intelligences expressed as a minus quantity.

News and Notes.

EXETER CAMERA CLUB.—The Exeter and West of England photographic exhibition will be held from March 13 to 16, 1923, under the auspices of this club, the secretary of which is Mr. Frederic G. Tutton, 9, Union Road, Pennsylvania, Exeter.

LAMBERT WESTON & SONS, LTD.—By an error on the part of the advertising agents, the address of Messrs. Lambert Weston & Sons, Ltd., appearing in the advertisement of Messrs. Ilford, Ltd., in our issue of last week, page ix., was given as 30, instead of 39, Brompton Square, S.W.

MR. S. GRIMSHAW, the well-known exponent of the Bromoil process, had joined the staff of Messrs. Kosmos Photographics, Ltd., Letchworth, Herts. He will be available for lectures and demonstrations upon the process during the coming season to photographic societies.

THE PROFESSIONAL PHOTOGRAPHER.—The September issue of the Kodak Company's magazine contains an illustrated interview with Mr. Arthur J. Winter, of Preston, accompanied by reproductions of his work in portraiture. There are also examples of the portrait work of Mr. Eugene R. Hutchinson, of Chicago.

HOUGHTONS' PROFESSIONAL BULLETIN.—The September issue describes new mounts and mottoes suitable for photographs as Christmas presents, and announces a new book "Studio Advertising," which has been written by Messrs. Houghtons' publicity manager, and is shortly to be published, price 2s. 6d.

PRESS PHOTOGRAPHERS' SALARIES.—"The Journalist," the organ of the National Union of Journalists, states that "after negotiations lasting several months the Union has made a new agreement as to salaries and conditions with the Proprietors' Association of Press Photographic Agencies." The text will be published in two or three weeks' time.

SUMMER TIME.—In consequence of the numerous inquiries which have been addressed to him, the Home Secretary desires to give notice that, in accordance with the Order in Council of March 15, 1922, Summer Time will not cease until 3.0 a.m. (Summer Time) in the morning of Sunday, October 8, when clocks will be put back to 2 a.m. The shorter period of Summer Time prescribed by the Summer Time Act, 1922, does not operate this year.

THE P.P.A. RECORD.—The third issue of the official monthly journal of the Professional Photographers' Association, shows that our contemporary is getting into its stride in regard to typographical setting as well as in respect to the arrangement of its contents, which in this issue are chiefly devoted to the current Congress. Mr. Hana gives the first draft of a scale of prices for commercial photography, and we note also the starting of a key to current photographic literature, consisting of brief indications of articles of interest to the professional photographer, published in the British and foreign photographic press.

INSTRUCTION IN PROCESS.—The prospectus of the day and evening classes in photo-engraving, held at the L.C.C. School, Bolt Court, Fleet Street, has just been published for the session, which opens on September 25. The school, as many of our readers know, provides a full course of training in the practical methods of half-tone block making, zinco and three-colour, flat-bed and rotary photogravure, and photo-lithography. The school is admirably equipped with all the apparatus for practice of these processes upon the commercial scale, instruction comprises, in each branch, lectures and practical work, and, in addition, there is a course of lectures on the principles of photo-mechanical methods by the principal of the school, Mr. A. J. Bull, to whom application should be made for the prospectus and for advice in taking up instruction in any given branch of work.

PHOTO-MAPPING MANHATTAN ISLAND.—Several of the American illustrated papers have published reproductions of a remarkable photographic mosaic map of Manhattan Island. "Popular Mechanics" gives a reproduction of the picture, also an account of how it was taken, and from the account we clip the following details:—"A hundred exposures taken at an altitude of nearly two miles resulted in a map, 8½ ft. long and 28 in. wide, showing more than 32 square miles of New York City, with every object, even to the pedestrians, plainly portrayed. The machine that made this possible is a large camera, weighing 36 lb., which uses a film similar to that of any ordinary camera, though very much larger, and having an electric timing device that regulates the exposures in proper relation to the speed of the aeroplane, from

which the camera is operated. The shutter exposes the film in 1-150th second—such a short period that the exposure is entirely unaffected by the movement of the aeroplane. The new camera is equipped with an automatic device for regulating the intervals between exposures in accordance with the speed of the aeroplane and by means of another innovation the roll film is held without vibration."

Correspondence.

*** *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

*** *We do not undertake responsibility for the opinions expressed by our correspondents.*

THE BEGINNER IN PHOTOGRAPHIC SOCIETIES.

To the Editors.

Gentlemen,—Most of the photographic societies are now waking into activity again, and the point is arising what to do with the beginners who will undoubtedly wish to join. If beginners are accepted for membership they should naturally be given instruction in the elements of photography, and helped in every way. This is a difficult proposition, and almost every secretary will say, "How troublesome it is to get members who are good workers, to instruct these beginners." My own point is that the beginner should not be allowed to join a photographic society until he has a good knowledge of exposure and development, and can produce a good printing negative. All photographic societies exist with the purpose of furthering the popularity and usefulness of photography, and if they are to be burdened with a batch of beginners each year then progress will be stopped.

I should propose that the absolute beginner get his early instruction from one of the numerous schools which exist in the London area, and then when he can produce a certificate from the instructor of such school that he has had at least one season's instruction he may be allowed to join the society. This would ensure all members of the society having a certain degree of photographic intelligence, and lecturers would not then have to answer the silly questions which are often asked them.

Yours faithfully,

A. V. W.

SYSTEM IN HALF-TONE OPERATING.

To the Editors.

Gentlemen,—I hoped that I had finished with the very long correspondence on the above subject, at least for the time being, but Mr. Sukumar Ray's letter needs a reply, so I must carry on.

As regards the much-discussed article by the late Mr. U. Ray, I think that it is an example of how the full intentions of an author sometimes fail to get home to the reader. As my disagreement with the penumbral theory as exemplified by his geometrical projection opens up a wide field for argument, I hope I may be permitted to defer this to a later period, when I may follow up the present discussion by again presenting some of my own conclusions on the subject of the theory of half-tone dot formation.

As to Mr. S. Ray's experience contradicting my own, there is nothing surprising in that. There are so many possible inconstants, and working conditions are so variable, that approximately the same results can be obtained in a variety of ways, which is quite sufficient to ensure that I should find many to disagree with me. In fact, I did not expect any agreement, because I know that much of my system is contrary to accepted practice. That does not alter the fact, however, that the results that I have described are being obtained daily by the methods I have advocated. When I discover any system that is simpler or more certain I shall not hesitate to change over.

The type of negative that I aim at is one that will print upon metal with a standard exposure and correctly represent the subject, or such variation as may be necessary, and give the etcher the minimum of trouble, and, above all, satisfy the customer. This is the only type of negative that interests me.

I am very pleased to note the results of Messrs. Turner and Hallam's experiments in "flashing" as described at the "Royal" recently. They are entirely in accordance with my own experience that the very small flash stops, as advocated in some quarters, are entirely unnecessary. I wonder if they could be induced to give a clear exposition of what they understand as the penumbral theory of dot formation?—Yours faithfully,

E. A. Bierman, F.R.P.S.

Birmingham, September 11, 1922.

SILVERING MIRRORS.

To the Editors.

Gentlemen,—We have just read in No. 3,251, issued August 25, of the "British Journal of Photography," page 509, that mirror silvering by the formic-aldehyde process has been studied in 1912 by Mr. Everett King.

This process was studied by Messrs. Lumière Bros., in 1894, and described in the "Journal de Physique Théorique et Appliquée," page 29.

Later on, in 1904, Messrs. Lumière made a slight change in their process, and the new formulæ have been regularly published in the "Agenda Lumière," ever since 1904. We may add that at the Lyons astronomic observatory, the mirrors for the elbow equatorial and the siderostat are being regularly silvered by the Lumière process.—We remain, Yours faithfully,

Lumière & Jougla.

Lyons, September 8.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 6-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

C. H. W.—You can manage half-length and bust portraits in the room you describe, but it is too short for full-lengths, the focal length needed for these being only equal to the longest side of the plate (see table on page 566 of the current "B.J. Almanac"). You will require, at least, 2,000 c.p. for professional work, the exposure with 400 c.p. being much too long. We should recommend you to have one large lamp fixed upon a movable standard so that you could get some variety in the lighting.

J. L.—The only substance which will serve to ignite coal gas is spongy platinum black, a special finely-divided form of platinum metal. Owing to the high price of platinum this material is very expensive, but apart from that we do not think it would be of practical use for your purpose, since the gas will take quite a material time to ignite, and, moreover, the platinum black gradually loses its power of ignition. We advise you to abandon this device, and use some form of by-pass for the gas actuated by the pressure back of the printer.

H. B.—(1) The body of the enlarger can be used as an enclosure for the source of light. (2) The condenser should be removed, or, better, replaced by a sheet of ground glass. (3) Certain patterns of strip printer can be adapted for use on the back of the printing box. (4) You should use some of the hard grades (see advertisements) of bromide paper, which have recently been introduced. (5) Either developer may be used, but considering your requirements we think M.Q. would be preferable. (6) It is usual to obtain permission, since a photographer has no legal right to exhibit a portrait in his showcase which has been made to a customer's order.

L. H.—It is evident that the copyright in the views is your property, and you appear to have assigned to Mr. A. the sole rights to sell prints, presumably in postcard form. Your transaction with Mr. B. does not appear to be very well defined, but if, as stated, it was understood that Mr. B. was granted the right only of reproducing the two subjects in a book, then clearly the issue by Mr. B. of the two subjects as postcards is an infringement of your copyright. This is how the matter stands as regards copyright law. As regards breach of contract, the matter is rather more complicated, and we think that Mr. A. is quite justified in his annoyance, and is entitled to remedies against yourselves for permitting the reproduction of the two subjects as postcards by Mr. B. It seems to us that the crux of the dispute is the precise arrangement which you made with Mr. B., but it seems doubtful whether this can be definitely established on either side if it came to any legal action.

G. K.—For enlarging on bromide paper we should think a single good, inverted, incandescent burner, such as the "Howellite," of Messrs. J. J. Griffin & Sons, Kemble Street, Kingsway, London, W.C.2, would be sufficiently powerful for fairly quick-printing negatives, but as yours appear to be of more than average density it would, perhaps, be necessary to have four. The objection to so many is the considerable heat, but in a vertical enlarger you should be able to arrange a good-sized light box and also ventilation above it so that the enlarging room does not become unduly heated. With four burners, two thicknesses of ground glass placed about one inch above the negative should give sufficient diffusion of light. One thickness of ground glass and one of opal would be better, but the opal cuts out a great deal more light, and if you can do without it, so much the better for the exposure with your dense negatives. For enlarging on gaslight papers, we do not think the light of even four burners would be nearly powerful enough.

S. A. J.—To strip a wet collodion negative proceed as follows:—When the negative is thoroughly dry and cool, flow over with thin solution of rubber in benzole, 2 parts pure rubber to 100 parts benzole, or ordinary cycle tyre repairing solution thinned down to about the consistency of collodion will do. When this is dry, the negative is flowed over with "leather" collodion. This is prepared by adding a small quantity of castor oil to plain collodion. A good formula is:—Celloidin, ½ oz.; ether, 5 ozs.; alcohol, 5 ozs.; castor oil, ½ oz. When the collodion on the negative is dry (and the drying can be hastened by heat) the negative is cut round the edges with a knife and placed in a dish of cold water. The film should soon begin to loosen at the edges; if it does not a little acetic acid (up to 10 per cent.) may be added to the water. The film is now transferred to a piece of paper, and thence to the new support. If the negative is to be reversed it is transferred to another piece of paper before being placed on its final support.

Q. T.—You have been using the wrong developer for warm tones on the Q-Tone paper. There are separate developers for cold and warm tones, and although the amounts of water, metol and hydroquinone are the same the other chemicals differ, as you will see in the formulæ which we give side by side:—

	Cold Tones.	Warm Tones.
Metol	80 grs.	80 grs.
Hydroquinone	80 ,,	80 ,,
Soda sulphite (crys.) ...	2,400 ,,	800 ,,
Soda carbonate (crys.) ...	2,400 ,,	—
Borax (powdered)	—	800 ,,
Potass. bromide	20 ,,	2 ,,
Water	80 ozs.	80 ozs.

Development should be conducted for a standard time at a standard temperature, so as to ensure uniform results. Two minutes at 65 deg. Fahr. will be found the most suitable. It is worthy of note that with this paper brief exposure and long development decreases contrast, while longer exposure with brief development gives vigour. After development a rinse of a few seconds is all that is necessary, and the prints should then be fixed in hypo 4 ozs., water 20 ozs. for ten minutes.

R. B. W.—(1) It is impossible to say without trying whether the formula can be made up with very much less water than the 20 ozs. From the look of it we should think it would be possible to use, say, 10 ozs. of water, but when a developer of approximately this formula is made so concentrated, some of the chemicals are liable to separate out in cold weather, and if that happens they do not redissolve again completely when the solution is warmed, so that the balance of the developer is upset. (2) We think it is only ordinary experience that a developer made up with caustic soda does not work quite as well with many gaslight papers as one made up with soda carbonate, owing to the greater energising power of the caustic alkali. Usually we should prefer a carbonated developer for gaslight papers. (3) You could add soda carbonate to the caustic, or replace part of the caustic alkali by soda carbonate. It is entirely a matter of experiment by trial with different quantities of the two alkalies. (4) Potass metabisulphite will improve the keeping qualities of almost any developer, but it renders the solution slightly less alkaline and makes it, therefore, less energetic, *i.e.*, slower in action. (5) The only two books which can be recommended—and both are now rather out of date—are the "Chemistry of Photography," by Meldola, Macmillian, 6s., and "Photo-Miniature," No. 149, possibly obtainable from Houghtons, or from the publishers, Tennant & Ward, 103, Park Avenue, New York.

T. T.—I think there is no reasonable doubt that, in the circumstances which you describe, you have acquired a legal title to the copyright in the photographs, since it is evidently impossible to show that you were ordered by anybody to do the work, or expected payment from anybody. In these circumstances the reproductions of the photographs are infringements of the copyrights, and both of the newspapers have not any good defence in the plea that they thought the copyright belonged to the —— family and that, therefore, they could use them without making payment to anybody. It was their business to satisfy themselves on that point before they reproduced them. One newspaper has written quite a reasonable letter, and while it is absurd for them to say that the fee of 10s. 6d. is charged only for photographs of royalty, there is some ground for their contention that small provincial papers, such as theirs, do not regularly pay the fee of 10s. 6d. per photograph. We believe that 5s. per photograph is a very usual fee for such papers. But, on the other hand, they are both of them now in the position of having reproduced without the permission of the author, and while we do not recommend that undue advantage should be taken of this fact, it might very well be pointed out to them that under the Copyright Act you have good ground for taking action in the County Court for recovery of your fees. As no doubt you know, the only defence which can be put up is that the infringers did not know and had no reasonable ground for suspecting that there was any copyright in the photographs. Obviously in the case of such recent portraits no one connected with publishing could suppose that copyright had become non-existent. We think if you point out these facts to the two newspapers you will have no difficulty in coming to terms with them.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3255. Vol. LXIX. FRIDAY, SEPTEMBER 22, 1922. Price Fourpence.

Contents.

SUMMARY.

The proceedings of the Congress of the Professional Photographers' Association are further reported in this issue. The co-operative advertising of photographic portraits was the subject of two papers, one by Captain F. H. Wright, of the London Press Exchange, and the other by Mr. Hopton Hadley. The great success which has attended the advertising of other products by this method was instanced, and Captain Wright outlined a working scheme on the basis of the number of profeasional photographers in the United Kingdom. (P. 572.)

Mr. Pirie Macdonald, of New York, delivered one of his stirring addresses. It was a vigorous appeal for photographers to rank themselves with their sitters in intellectual interests and also to work for the realisation of their own ideals in portraiture. (P. 574.)

Mr. Herbert Lambert delivered an excellent address on the harm which was being done to photographers as a whole by want of confidence among themselves, particularly in the provincial towns. (P. 579.)

Mr. Frank Brown dwelt upon some of the unscrupulous methods employed in obtaining business. (P. 580.)

At the meeting to which assistants were invited, Mr. George Hana strongly expressed his hope that means would be found of bringing them in some form within the Association. (P. 578.)

Visits were paid to the National Gallery, National Portrait Gallery, and to the process works of the Amalgamated Press. (P. 581.)

A reproduction of the group of Congress members, photographed by Mr. W. B. Chaplin (Russell and Sons) on the East Terrace of Windsor Castle, will be found on page 576. A key to the portraits in this group will be published next week.

The sixty-seventh annual exhibition of the Royal Photographic Society is now open at 35, Russell Square. Mr. Solomon J. Solomon, in performing the opening ceremony, spoke most appreciatively of the pictorial effort in photography, and particularly commended certain exhibits. (P. 567.)

Mr. F. C. Tilney contributes a review of the portraits in the R.P.S. show, in which this class of subject is more largely accompanied by landscape than at the Salon. (P. 568.)

Landscape and genre subjects at the London Salon are reviewed in a further paper by Mr. Tilney. (P. 570.)

In a leading article we refer to the sources of profit which still remain very partially utilised in connection with the amateur's snapshots. Apart from developing and printing, which may be very profitable, or the reverse, according to circumstances, there is an untapped field in the supply of the best possible reproductions of small snapshots. (P. 566.)

At the Croydon Camera Club last week, Dr. D'Arcy Power lectured on the making of pastel drawings upon a two-colour photographic print obtained by toning. (P. 583.)

Some practical points on the use and fitting of an antinous release to a hand-camera are the subject of a paragraph on page 566.

The circular or oval shape may at times be chosen for a portrait, as was often done by the great painters. (P. 565.)

EX CATHEDRA.

The P.P.A. Congress. Last week's Congress of the Professional Photographers' Association has passed, leaving a host of pleasurable memories in the minds of the 291 members who attended it and a mass of reports of its proceedings, the whole of which, at the time of writing, we are afraid cannot be included in the present enlarged issue of the "B.J." Perhaps the subject which aroused most attention was that of co-operative advertising, which formed the subject of the addresses by Captain F. H. Wright and Mr. Hopton Hadley. It is a large project, one which has already been discussed in our pages during the early part of the present year, and also one which the P.P.A., if and when it comes to deal with it, must necessarily approach in a broad spirit. We will postpone further reference to it to a later issue, when our professional readers will have had the opportunity of studying the two papers which appear on another page this week. The assistants' evening was also a function embodying a less definite scheme, yet one which we hope will contribute towards linking assistants in photographic studios more closely with photographers as a body than has hitherto been the case. To these references to what has been a notable week, we must add a word, by way of warm appreciation, on the debt which the Association owes to its secretary, Mr. Alfred Ellis, upon whose shoulders a large part of the work of organisation has fallen. Without hurry or flurry, and with the genial diplomacy which is his, Mr. Ellis has carried the responsibility for an enterprise which was somewhat ambitious and which encountered numerous difficulties. He handsomely deserves the thanks of the Association.

* * *

Print Trimming. In these days of artistic, or perhaps in many cases "arty," photography, those who practise it seem very much afraid of departing from the rectangular form for their pictures. This is rather a pity, for very often the composition or balance of a portrait can be greatly improved by trimming it to an oval or even to a circular shape. It is not a bad plan to have on hand a few zinc ovals and circles in the sizes mostly used, and to try the effect of these upon prints which do not seem to be quite what is wanted. Photographers need not fear to use these forms, for many of the greatest painters have been glad to avail themselves of them. The circular Madonna of Raphael is an outstanding example. An actual square or a rectangle of nearly equal sides is also taboo with many workers, but in some cases it is just the right shape for the subject. Fortunately, we are free from the fetters of stock-sized mounts which called for standard sizes and shapes in prints. Now, an oval or a circle or a square may be mounted without the once indispensable line or plate mark.

The Antinous Release. With the approach of autumn, and the decline in the strength of the light, users of small cameras would do well to make sure that the apparatus they use is fitted with convenient and satisfactory means of giving time exposures when it is used on a stand. Cameras of quarter-plate size and over are invariably provided with some kind of flexible release, either ball and tube or antinous wire; but one meets very many of the smaller type where the only means of operating the shutter is a small trigger. Now, this is all very well for snapshot work, but when time exposures are attempted, the danger of introducing blur into the negative by movement of the front, or of the whole camera, is very great. Lack of stability between camera back and front makes these trigger-operated time exposures next to impossible with several types of small instruments, and one wonders why the antinous release does not become a universally adopted fitting for them. Most shutters are provided with a hole into which one can be screwed. In buying an antinous release, care should be taken not to get too short a one, as this kind produces almost as much camera movement as operating the shutter by trigger. They are made small, so as to fold up with the camera, but if a subject is worth the trouble of erecting a tripod, or selecting a suitable firm base, the slight extra work of taking a release from the camera case, and screwing it into position, will not be felt. Another point worthy of mention is that, in use, the antinous release should be kept as straight as possible. It can be held so bent that, in firing the shutter, it imparts considerable shake to the camera.

MONEY FROM SNAPSHOTS.

It is impossible to estimate, with anything like accuracy, the percentage of the population who use cameras of some sort or other. At most of our holiday resorts about half the visitors seem to be victims of the snapshot habit, and if this proportion is not maintained all over the country, it is a certainty that there are few families outside the poorest districts which do not contain one or more amateur photographers.

In past years the professional photographer looked upon the amateur as his natural enemy, or perhaps rather as a noxious weed which ought to be eradicated, and drove him into the arms of the chemist or other dealer from whom he had purchased his materials. This was in many cases due to the fact that the amateur had to do his own developing and printing, and discovered that a little profit could often be made by selling his productions usually at a ridiculously low price. This epoch has, however, passed away, and only a very small percentage of amateurs do their own finishing, and fewer still make any money out of their hobby. Therefore it will be seen that our title does not apply to any revenue accruing to the makers of the negatives, but to that which may be directed into their own coffers by intelligent professionals.

Every photographer must judge for himself whether it is to his advantage to take up ordinary film development and printing. If enough of this can be secured to put in a proper "amateur finishing" plant of tanks, printing boxes and film and print-drying machines, and also to engage special assistants, the work is worth doing, if the prices be not unduly cut, but the portrait photographer with a small staff and no special appliances will be well advised to leave it alone. It is in quite another direction that he must look, that is to say, in the production of the finest possible results from amateurs' negatives, and that at highly remunerative rates.

When we consider the amount that is spent upon such hobbies as golf, fishing, motoring and even gardening, it is perfectly clear that the money is there to be spent upon photography, if it can be shown that the results will justify the outlay. One who has had a long experience in this direction has testified to the business which has been done in oil paintings—business, running into three figures from amateur originals—of albums filled with enlargements, sets of lantern slides, often coloured, and many other branches of work.

The orders which reached photographers during and after the war should have shown them the value of the snapshot as a starting print. In how many cases was the only portrait of a son, brother or husband a little crumpled bromide print often scratched and worn? It would be carried about, before the knowledge that it could be reproduced in a permanent and glorified form occurred to the owners.

Some few words of advice or suggestion may be useful to those who have never given this matter their attention. The work must be approached with the intention of doing the very best that can be done in the circumstances, or it will be useless to expect to obtain a good price for it. First-class technical skill is necessary and the services of a really good finisher are essential, the first to carry out the work in the most suitable medium, and the second to give it the appearance of a good original photograph.

An example of a job actually executed is worth more than any amount of generalities which are apt to lack convincing power, so the following details are given. A rather poor V.P.K. print of a deceased officer is brought in and the photographer is asked if he can copy it. He agrees to do so, and inquires as to the size required. To this the reply is, "As large as possible," the price being left unsettled, as the customer appears prosperous. A copy negative is made rather larger than the original, and enlarged without retouching to 12 inches in height, a diffusing screen being placed in front of the lens. After mounting, the print is rubbed over with an oil medium and given a thin coating of warm black oil pigment, mixed with the same medium, all over the surface. This is roughly applied with a hog-hair brush and distributed with a pad of cotton wool. Without allowing this to become too dry the high-lights are wiped out with a soft rag, and the shadows, where necessary, strengthened with more pigment applied in the same way. Fine details are now put in with a sable brush, and finally, as the background is rather ugly, it is darkened with the pigment until a harmonious appearance results. It now resembles a good mezzotint, or, as one amateur said, a "fine Bromoil." At any rate, it was not considered dear at the five guineas which was charged, and, moreover, a dozen cabinet copies in platinum formed an agreeable supplement from the photographer's point of view.

If the photographer be a good business man, but lacks facilities for doing such work, he should secure the order and place it with a *first-rate* trade house, and pass on his instructions to make the best possible job. Even this will leave him with a profit of 100 or even 200 per cent. upon his outlay. It goes without saying that one or two specimens showing the original and the copy are very helpful in getting orders for this work. The old professional print and copy do not carry conviction like the snapshot.

ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.

The house at 35, Russell Square was opened on Monday last for the sixty-seventh annual exhibition of the Royal Photographic Society. During the vacation the premises have been thoroughly renovated, and some changes made which, we think (although it does not appear to be the general opinion) are decided improvements. Volumes of periodical publications, which previously had been almost inaccessible in the room on the ground floor to the rear of the library, have been transferred to the library and accommodated in a large lot of shelving placed between the two windows and dividing this part of the room into two bays. Although the room is thereby somewhat darkened, it acquires a real library atmosphere, and the convenience of having every book in the Society's possession close at hand is one which is surely an advantage to the members. Moreover, the transference has enabled the rear room to be completely cleared, and this year it accommodates the Nature photography section of the exhibition, which is there well hung and quite well lighted.

The pictorial section is undoubtedly the best which has been brought together since the Society has held its exhibitions in its own house. This is perhaps due to the rigorous selection. Only 154 prints are shown. We think the Society is right in making the inclusion of an exhibit a real distinction as the result of a close weeding out of the inferior. The technical sections this year are also of greater interest. The Autochromes are lighted by direct electric light instead of by the mirror system previously employed, and there is a large display of lantern slides, perhaps rather too large a one, for the exhibit would have been somewhat more effective had the transparencies been separated by intervening dark spaces.

A full programme of lectures will be delivered during the period of the exhibition, each Tuesday and Friday evening at 8 p.m. To-night, Friday, September 22, the fixture is an exhibition of Affiliation competition lantern slides. Mr. Dudley Johnston will personally deliver the criticisms which he had prepared in course of making the awards. On Tuesday next Mr. Johnston will deliver a lantern lecture, entitled, "From Alp to Apennine." Among other lectures are those on Lourdes by Mr. T. H. B. Scott, on Carcassone by Dr. Atkin Swan, and on Aerial Photography by Major F. C. V. Laws. The exhibition remains open daily from 11 a.m. to 9 p.m. (Sundays excepted) until Saturday, October 28. Admission is free.

The technical section this year is both larger and of greater interest than in the case of the previous three or four exhibitions. Owing to the great pressure upon our space this week, caused by the reports of the Congress of the Professional Photographers' Association, reference to this part of the R.P.S. show must be postponed to a later issue.

Below, Mr. F. C. Tilney reviews the pictorial section which, it will be seen, he specially commends for the balance between different classes of work which has resulted from the choice of the selecting committee.

MR. SOLOMON J. SOLOMON, R.A., ON ART IN PHOTOGRAPHY.

The exhibition of the Royal Photographic Society was opened on Saturday afternoon by Mr. Solomon J. Solomon, R.A., President of the Royal Society of British Artists. Mr. W. L. F. Wastell, the President, who was in the chair, mentioned that the first of the Society's sixty-seven annual exhibitions was held under the Presidency of Sir Charles Eastlake, who was also President of the Royal Academy. Mr. Solomon stood for all that was highest and best in English art, and on behalf of the Council and members he offered him a very hearty welcome. In his own opinion the exhibition was the best and most complete ever held in the Society's rooms. He paid a tribute to those who had undertaken the vast amount of work entailed in its organisation and preparation. Special arrangements had been made for showing the lantern slides and colour transparencies to the best advantage; there was better separation of sections, and an improvement in the lighting of the main gallery. On the general question on which Mr. Solomon might speak, it was his opinion that fundamentally the photographer and the artist had almost everything in common. They lived in the same world, looked up at the same sky, reverenced the same truth, and loved the same beauty, and each strove in his own way and by his own methods to express it to others.

Mr. Solomon spoke gracefully and encouragingly on the relationship between artistic photography and the craft of the professional painter. Both, he said, were out to make pictures. The essential laws of composition, including grace of line, balanced grouping, decorative spacing, and massing of light and shade, influenced the discriminating photographer as they did the painter. Photography did much to raise the general level of taste in this country. There were several ways in which the painter was indebted to photography, apart altogether from the use of it which was made by the incompetent draughtsman. For one thing, it increased the knowledge of anatomy, and made possible the accurate study of the quick movements of animals and birds. Painters and sculptors even in high places sometimes made their horses, for instance, perform anatomically impossible feats, and the public, and perhaps the critic also, passed this by unheeded because crusty tradition was a "die-hard," and new-found truth made slow headway when the scientific outlook was lacking. Photography also availed to quicken the art student's perception of corresponding tone values, which in photography, of course, were simplified to monochrome. The Dutch masters and a few of the Spanish excelled in their appreciation of these subtleties. Then, in these days of alarums and excursions, when it was often forgotten that the function of art was to grace life and not to astonish the native, photography, by holding up the mirror to Nature, should have a salutary influence. Ironically enough, "stunts" were encouraged by the critics as a protest against the "photographic outlook." He would like the critics to come to that exhibition and define what the "photographic outlook" was. After all, art was founded on Nature, and photography would always give the facts, however they might be recorded *à travers témperament*. Such was the glamour of passing fashions that only the other day he had to say to a young Academy student, "Remember that for you your eye is the lens of a camera." Ten years ago that remark would have hall-marked him as a hopeless Philistine.

Mr. Solomon then reviewed some exhibits in the galleries. He congratulated the organisers upon their catholicity. There was something to satisfy the most exigent of art lovers, and something to interest the scientist. Among the latter he instanced the photographs of giraffes in their natural environment, showing their actions in a manner which could never be seen in any Zoo in Europe. Among the pictorial works he was astonished at the number of convincing compositions. Members of the public had a good deal of prejudice against hanging photographs on their walls other than those which they had taken themselves; but the most cultured person need not fear to hang pictures like these in the best parts of his house. He referred particularly to Mr. Luboshey's portrait of Sir Henry Trueman Wood, which was to him an astonishing piece of work, giving even in monochrome a vivid suggestion of the colour and texture of the flesh and hair. It reminded him of a good Orchardson portrait, and Orchardson was one of the finest of our portrait painters. Among the colour transparencies he found evidence of much progress.

Some flower studies struck him as almost perfect, and so did a stereoscopic picture of gems, which made his mouth water. The colour prints he found to be charming productions, better, he thought, with their mere suggestion of colour, than if they had the complete colour of the transparencies. Altogether he agreed that there was a very close relationship between the painter and the artistic photographer. "We use the brush and you a machine, but you use the machine like a fiddler his fiddle, with great mastery, and the rest is a matter of taste."

A vote of thanks to Mr. Solomon was proposed and seconded by the two Vice-Presidents, Mr. Dudley Johnston and Mr. T. H. B. Scott respectively, and Mr. Solomon, after thanking the audience, virtually promised to lecture before the Society in the course of the session.

THE PICTORIAL SECTION.

Every year and in every department the Royal Photographic Society's Show grows better and better. This rather overworn formula is remarkably fitting in this case; for the R.P.S. has been most assuredly emerging for the last three or four years from the cloud under which it mourned so long in the past. It is, by sheer fortitude and high endeavour, living down the prejudice and misrepresentation which, Heaven only knows why, fell to its lot; and in spite of the disqualification of having no proper picture gallery in which to hold its shows, it continues to attract the work of the very best workers at home and abroad. Its indefatigable well-wishers labour for it with astounding enthusiasm and self-sacrifice, and this alone is what tells in the long run. They have this year made further improvements in the lighting by ingeniously screening the ceiling and frieze from the free light of the handsome lamps recently installed. This plan does much to mitigate the glare in the glasses covering the pictures. Nevertheless, the quality of the works and the comfort of visitors would be still more assured by omitting the glasses from the top line of prints, which are, after all, quite out of reach of any risk against which the glasses are a safeguard.

The Portraits.

Unlike our friends in Pall Mall, the Selecting Committee have not plumped for portraiture, but have limited it to less than 20 per cent. of the whole pictorial display, and of these Pirie MacDonald claims four. They are four very good ones, and though seen in this gallery quite recently, are as fresh and dominating as ever. They are "Frank Lawrence" (142), "William Rockhill Nelson" (145), "His Grace the Archbishop of York" (148), and "Dr. Frank Crane" (152). Near them hangs another of about the same scale by J. Van der Pant, who calls it simply "Man" (154). It is virile and artistic, and although on more ordinary lines than those of Mr. MacDonald, keeps its place beside them very well. Herbert Lambert also shows four, of which the most striking in artistry is perhaps the little girl "Mary" (67). The dark hair of the child supplies all the weight there is in the tonal scheme, and is well placed in the field; the dress is but a thought lighter than the background, but that subtle difference in tone makes the print a thing of beauty. "Arnold Bax" (10) looks to have more gentleness of soul than one could have imagined in the producer of those fearless dissonances which characterise a modernist's music. "Oliver" (100) is a quite young baby, nude, taken at about lifesize—a scale which seems a trifle beyond the occasion. Marcus Adams also gives us four prints—a most affecting collusion, evidently, amongst these professional magnates—"Patricia Mary" (56) is a dainty picture of a maiden in columbine skirts. "Love Sisters" (59) a perfectly beautiful idea in posing, shows two semi-nude children, one fair, the other and elder, dark, whose arm reaches round her younger sister. The lines of this little group have been studied to some purpose, and it is difficult to see how they could be improved. The quality of the print is likewise exquisite. The "Eldest Son of F. J. Loveday, Esq." (66), is still a youngster, and seems to be rather taken with the semi-nude idea. "Zara the Piper" (63) is a little girl, in a classic robe this time, seated against a plain piece of wall between two curtains. The pattern of her figure, with its uplifted arms holding a Greek flute, comes with a gentle strength of tone against this light background, in itself glowing and beautiful by reason of the gradation it holds.

Another work which stands out as being due to conscious artistic intention and effort is Miss Kate Smith's delightful "Florinda's Fan" (1). Light, airy, graceful and charming, this is deservedly put where it meets the visitor's first gaze. The posing has that touch of affectation which the subject demands. The corner of the fan melts into the light tone of the background, and in other ways there is a charming "come and go" of the tones at all parts without loss of reasonable solidity. H. van Wadenoyen, Junior, admirably fills the space in "The Quizzing Glass" (7), a gentleman standing and reading a document through a small monocle. A little less novel, but excellent nevertheless, is his "Portrait of Miss C." (2). Mention ought to be made of a capital portrait of a dog called "Winton" (3), by Mrs. G. Bontor. "The Squire's Daughter" (8) is interesting almost entirely on account of its being the work of two ladies, D. and R. Morter, who have made a most creditable show at the Salon. Had it not been for that fact, the present print would have challenged no comparison with the better work, "The Master of the Fox Hounds," who is the identical squire's daughter. However, the print has quality, and on its own merits deserves its place here. "Unseemly Mirth" (12) is a better proof of its authors' power of characterisation. It is a picture of a guffawing serving maid, and although hardly a thing of beauty, is distinctly an attractive print. The severity of the style adopted by Chas. Borup for his "Mrs. Frank Bailey" (16) is evidence of a chastened taste, not belied by the utterly different and very captivating "Little Sweetheart" (71), who looks smilingly over her shoulder like a little Lady Hamilton. Another rather severely handled portrait is "The Tartan Shawl" (9), by E. Drummond Young, a lady seated full-face. It is carried out with technicality above reproach. "Miss Cynthia Fane" (19) is Lionel Wood's only portrait here, but it is an uncommonly good one, with a fine pose and expression and first-rate quality.

Of the work of N. E. Luboshey it would be unreasonable to say that we never have enough, because there is no one who is so consistently working hard and doing the best work. In view of his amazingly successful X-ray work here, it is all the more surprising to find that he can take his place with ease in the front rank of artistic portraiture. We must submit then to his preference for the scientific section, realising that his ewe lamb in portraiture is better than any example of his exhibited elsewhere, and possibly his best of all. 'Sir Henry Trueman Wood" (21A) is a work that will be regarded as a classic in days to come. It is instinct with style and feeling. That it is triumphant technically goes without saying, and whether it be a matter of modelling, textures, quality, or character, ample satisfaction and increasing appreciation result.

J. Furley Lewis, who has done, it seems, with the life of a recluse, shows a most animated portrait of an engineer at work over his plans, and looking up with an air of apologetic powerlessness to lay down his pencil. The title is "'New Works,' L. and N.W.R., Euston (Richard Cooper, Esq., M.Inst.C.E.)," (50). Another lively and eminently capable portrait is that of "P. R. Salmon, Esq., F.R.P.S." (52), by Halksworth Wheeler. "Jim" (79), by Miss Doris Galloway, is dull but otherwise fine. But Miss M. Curwen's head of a middle-aged lady, whom one would have to get up early in the morning to "best," is particularly lively in its tones and expression. Miss Curwen calls it "The 'Daily'" (83), and has used commendable judgment in

getting her effect of the household terror by presenting her face in all but life-size, trimmed close, so that the "close-up" effect gives the impulse to surrender on all points. Another good type is Chas. Wormald's beautiful print entitled, very aptly, "From Boy to Youth—and so to Manhood" (87). The merging of shadow into background is a fine touch. Ralph Jones achieves a velvety dark quality in "Peggy" (140), and Gilbert N. Futcher, A. C. Jacobs, and A. Howard Garmston each send work of a high order.

Figure Subjects.

Almost a silhouette in the shaded rags seen against a blazing sky, "Watching the Flock" (17) is a very forcible piece of out-door genre. The old beggar-man who shades his eyes with his hand is a picturesque character, but the chief merit of this work lies in the sensation Mrs. A. Ralli gives one of merciless sunshine. Two men looking over a document together (45) offers an unhackneyed theme in posing, and Gilbert N. Futcher has made a good thing of his theme.

Dancers and athletes are still enjoying their day. They come as a connecting link between the stark nude and the fancy costume subject. The best, from the artistic standpoint, that we have yet seen is certainly the work of Drtikol, of Prague. "Kupferova as Dancing Star" (141) and "Kupferova as Egyptian Dancing Star" (112) are the cumbersome titles of two very luscious prints. But the first-named is far and away the better. It exhibits two figures of women—a Circassian and an Ethiopian, presumably, both beautifully posed with regard to relationship of tone, made possible by the white and dark skins of the ladies. The high light on the fair woman's torso is a superb culmination. Everywhere the shadows are marvellously translucent, though very dark, and the whole thing is harmonious, limpid, and rich. To look from this print to the "Athlete" (129), sent by Bertram Park, is to realise how much the beauty of photographic pictures is discounted by sharp contrast of a light figure against a dark background without any play of transitional tone. His "Study" (125) is the figure of an artist's model playing panpipes against one of the columns of the Earl of Carnarvon's now well-known classic summer-house. L. J. Steele exhibits the same thing except that he places the lady the other side of the column and alters the pose slightly in "La Sirène" (75). The beauty of these pictures is the physical beauty of the model, which is considerable. Nudes on a larger scale and without a setting of any sort are sent by C. Pollard Crowther and Dr. R. S. Lovejoy. These again have a great similarity in motive; both are "crouching," both turned the same way: but whereas the "Nude" (96) of Dr. Lovejoy fills the space of the print with a good sense of design, Mr. Crowther's "A Pose" (28) leaves much space that looks empty. In other respects his study will give more delight, for it is lit with skill and faultless taste, and it has the smooth, velvety texture that is a legitimate attraction of such a subject. The other has no modelling at all, but is a broad, big treatment which in its way is fine. A semi-nude boy between his mother's knees is another arresting print by Drtikol, called "Mother" (151). It has a fine design, not unlike a famous Madonna of Raphael, and, indeed, since there is a suggestion of a halo round the mother's head, we may take it that the idea implicated is a devotional one. No words can over-praise the splendid posing and fine choice of types in this remarkable work of art. We finish this section of work by a reference to Angus Basil's "Young Dancers" (46), a young man and woman in a pose recalling Russian ballet. The print has much quality.

F. C. Tilney.

TRADE EXHIBITS.

The vestibule and stairways at the Society's house are occupied, as in previous years, by wall displays by leading manufacturing firms. Messrs. J. H. Dallmeyer, Ltd., show some striking enlargements of sports and Nature subjects obtained with their large aperture lenses, and two delightful portraits by Mr. Herbert Lambert taken in soft-focus by the Dallmeyer objective.

The Autotypo Co. make their customary effective display of the technical and pictorial merits of carbon prints in the shape of results by the ordinary carbon process and by Carbro. There are several pairs of specimens of the latter process showing the remarkable quality of the Carbro in comparison with the bromide print from which it is made.

Messrs. John J. Griffin & Sons have some beautiful professional portraiture printed on their "Noctona" and "Goldona" papers: their contributors are Messrs. Charles Borup, Reginald Haines and Nixon E. Payne.

Messrs. Wellington & Ward present a very striking display of prints and enlargements representing the pre-eminent qualities of their bromide and gaslight papers, in particular the B.B. brown-black papers and the recently introduced Q-tone varieties. Seltona likewise figures here as a Wellington product consequent on the recent acquisition of the Leto Co. by the Elstree firm. Negatives, in every instance, are on one or other of the Wellington plates.

Messrs. Amalgamated Photographic Manufacturers, Ltd., show a striking collection of examples of work made with the plates and papers manufactured by their constituent companies by Mr. C. P. Crowther.

The exhibit of the Kodak Co. consists entirely of the highly pictorial portraiture of Mr. Hugo van Wadenoyen, in the shape of prints on "Kodura Etching Brown" from negatives on Eastman Portrait film. There is a further display by the Kodak Co., on the staircase leading to the first floor of the house. This consists of prints on Kodak "Royal" bromide paper from negatives made by Mr. N. E. Luboshez on the Eastman Portrait film at a demonstration of portraiture by artificial light given to the Society last winter. It is a series of fine portraits in the making of which no retouching has been done on either the negatives or the enlargements.

Messrs. Robbins, Manistre, the London Camera Exchange Co., Ltd., show the latest issue of their catalogue of second-hand apparatus.

On the staircase connecting the first and second floors of the house Messrs. Taylor, Taylor and Hobson show a remarkably fine series of enlargements from negatives taken with the renowned Cooke lenses. These are of sports subjects in rapid movement, football, diving, and motor-cycles, and demonstrate by their great scale of enlargement the remarkably fine definition of the original negatives.

Death of Mr. W. G. Lewis.—We regret to see the announcement of the death of Mr. W. G. Lewis, of Bristol, at the great age of 78. Mr. Lewis spent his early youth under Horatio Nelson King, the Court photographer to Queen Victoria, and himself was later appointed photographer to the Prince of Monaco. For many years he carried on his business in Seymour Street, his name being well known throughout the West of England. He had four sons, all of whom are photographers in various parts of the British Isles (one being Mr. H. R. Lewis, head of the "Bristol Times and Mirror" photographic staff) and two daughters.

Held Over.—Owing to great pressure upon our space this week by the reports of the P.P.A. Congress and Royal Photographic Society's exhibition, many paragraphs, letters, and answers to correspondents are unavoidably held over.

PICTORIAL WORK AT THE LONDON SALON.

In several respects one feels a haunting conviction that this year, at any rate, the Salon is making a little halt in the unquestionable advance it has achieved since it rose, phœnix-like, from the ashes of the old Linked Ring. Amateurs of landscape and subject-picture seem to be marking time, and there are no recruits to speak of. Perhaps the passing of the subject-picture or anything with a strong literary interest, is not so much to be deplored; since genre or anecdote is apt to lead the photographer away on to the quagmire of picture-building and faking. That is a pastime requiring supreme taste, skill, and knowledge as safeguards against artistic death; and not everyone is a Polak or a Guido Rey. But even Mr. Polak has at last done with his series of old Dutch Masters, with which he distinguished himself.

When landscape is considered, one must openly deplore the fact that the newest ground of artistic exercise, in which photography had set a firm foot, should begin to show signs of a waning attraction. One looks around the gallery only to see in great preponderance heads and figures that can only legitimately be classed as portraiture of that kind which is practised for commercial ends. It will soon be a misnomer to apply the term amateur photography to the London Salon Exhibition. Nor is the R.P.S. very different in this respect; since its recent one-man shows have been very much of the professional show-case order. What, then, is happening to the amateur? Enquiry elicits the information that the proportion of portraiture to other classes of work at the Salon, is practically the proportion of the entries. The fault, therefore, if we agree that it is one, is the amateur's own. He is giving place to the professional. Nobody doubts that the professional wants, and should get, all the encouragement he can on artistic lines; and if he is alert enough to get it by enterprise, good luck to him. That the effort is genuine is apparent in the fact that his "body" is arranging personally conducted tours of the national picture-galleries; and that is the most hopeful sign in trade since photography became a trade. But where, again, are the amateurs; they, whose souls are supposed to be above all thought and consideration of interestedness; who form clubs and societies for the encouragement of their art, the acme of which is an incentive to pot-hunting, amongst themselves and the dealers they support? To them, apparently, the picture-galleries do not appeal, at least I never, but once, heard of a camera club going to a picture-gallery, and that was only a private and informal gathering of two or three.

However, those who are still faithful to lofty ideals should be honoured; and it is my privilege to direct attention to their works.

One of the earliest exhibitors among amateurs is certainly Alex. Keighley. He has steadfastly persevered in a determined course of pleasing himself, and as his judgment is trustworthy, the process has been vindicated. His work this year shows none of the laboriousness that in former examples seemed to be necessary to produce a print. "The Castle Hill" (30) is free from obvious retouching, and is no less full of the romantic feeling that we look for in Mr. Keighley's works than the laboured prints have been. This one is a view of a ravine through which a gleaming river runs, and on whose sides grow the cypress trees. The sky is cloudy. Are not Mr. Keighley's skies usually cloudy? At any rate that of "The Turnip Field" (85) is effective because it has character and makes the picture. This is one of the finest subjects he has ever exhibited here. "The Fishermen's Shrine" (88) has the smooth quality of a mezzotint, and is but one degree less delightful than "The Turnip Field." "The Church Steps" (294) seems to be in want of more contrast in the tones; it is an enticing subject.

F. J. Mortimer sends, in my humble opinion, the finest landscape work he has yet shown, in "Storm Clearing Off" (71). It is in a beautifully light key, which is exceptional in Mr. Mortimer's sea work, yet the tones are rich. It has a grand and dramatic sky; the water in the bay is a turmoil of heaving weight; and the rocks are full of construction and detail, which is a change from the usual black lumps of under-exposure that coast scenes usually offer. "Solitude" (191) is the characteristic Mortimer of sea and clouds; but impressive and poetical.

J. H. Anderson does not surpass himself; that would not be easy; but he stirs our interest more than usual by some new and splendid subject-matter. I have often wondered when photographers were going to discover the unearthing of St. Magnus by the disappearance of the "Pearl" buildings, and who would be the first to do it; and, lo! it is J. H. A. His "Changing London" (126) is a clever piece of selection, made from the river level. The big barges beneath the bridge are admirable foreground stuff. The whole thing is rich in tone, and so fine in design as to make the true Cockney's heart flutter with pride. The other version, "Changing London" (129), shows the clearing before the church, and makes an equally effective picture though not so traditionally pictorial. It is dark, of course—these photogravures always are—but there is a delicious sparkle in its depths, and the handsome church tower is looking its best. I do not know how the monument got out of the vertical; but I know it has recovered now, for I saw it on Sunday last. Visitors should note, also, the sound art of "Riverside Works, Hammersmith" (146), and the technically accomplished "London Terminus" (149) with its sunlit crowd, also by Mr. Anderson.

Whilst speaking of London, mention should be made of Hector Murchison's very noble "Construction—London's New Town Hall" (39), fortunately photographed before the anti-climax tiled roof literally "put the lid on" what might have been a dignified structure. Mr. Murchison, taking a leaf from the book of Muirhead Bone, shows us the charm of scaffolding, and secures one of his finest subjects. The antithesis in subject matter is chosen by Charles Job, who deals with the past glories of the Renaissance. "In the Garden of the Villa D'Este" (46) cannot be called a new find, since it is the most be-painted of any of the Italian gardens, and deservedly so. Mr. Job does, however, get a rather new point of view in confining himself to the stairs and vases, with which he makes a picture magnificent in design, and adds to it all the delights of colour, texture, and historical romance. Similar qualities exist in P. Dubreuil's "Dream's Garden" (412), which looks like the cascade of St. Cloud.

London, again, has inspired W. H. Reece and Ward Muir. The first shows Hyde Park Corner, with a true atmosphere in "London Landscape—A Rainy Day" (58), and the latter "Cannon Street Station" (59), with true daylight, and a new view (for which many thanks) from the river level. A rainy day in Venice is something new in pictures, and Chas. A. Davies intensifies the effect by his fuzzy treatment of "The Piazza San Marco" (233). In S. Bridgen's imposing view of "The National Gallery" (282) natural effect is dominated by pictorial effect. He has given the dear old place the majesty it possessed before it was overtopped by the gaunt hotels on the south of the Square; it is an eminently happy selection.

Natural effect in landscape is not a strong feature of the show this year, but a notable example is set by J. Arthur Lomax in "Sunlit Yard" (18), which really dazzles by the glare on the white walls. A. C. Banfield uses a similar theme, but with a less intense effect, in "A Corner of the Farmyard" (35). F. O. Libby's "Nocturne" (64) is a blue-tinted print in which respect, as in its general design, it is obviously a sincere form of flattery of Whistler. His more photographic theme, "The Curving Way" (94) is perhaps more commendable on this account, though it is decidedly fuzzy. This gentle- is evidently a favourite with the Selecting Committee, having ten specimens of his work on these walls. An extremely fine effect is depicted in a landscape by W. J. Clutterbuck, who

ennobles it with the impressive title of "Winkles" (65). On the other hand "Le Val D'Estang' (117) is a high-sounding phrase that fits exactly the romantic and imposing mountain scene sent by M. O. Dell.

Photographs of landscape owe their finest laurels to natural effects. However fine the composition, a touch of weather, let it be hail, rain, or shine, gives it a content which has a universal appeal. The argument is borne out by J. M. Whitehead's "Rain on the Hill" (280), "The Mosque—Moonlight" (112), by F. de la Mare Norris, Dr. R. S. Lovejoy's "Nocturne—by the Sea" (144), with its moonlight on the water (I say nothing of the empty silhouettes of the foreground trees), and his even more subtle "New England Nocturne" (188) with the exquisitely true tones of moonlight on snowy roofs. Bertram Cox's "Storm at Brentford" (246), the remarkably fine and simple weather-piece by J. A. Lomax, which he calls "Cloudy—probably some rain" (250), which is one of the few great landscapes here, Dr. R. E. Evans's "The Shadow of Night" (288), and "The South Downs" (295), by Chas. Job, with its magnificent sky. All such works, showing observation and love of Nature, profit by the quality of variety of tone brought about by their respective motifs, even when it is the gentle effect of lighted windows, as in the successful "Evening" (60) of Oskar Teiwes.

A few prints give that mysterious dignity which always impresses a spectator, such as the immensity of the iron vessel in Mrs. Milson's "In the Graving Dock" (407); the big trees in Bertram Cox's "Evening Shadows" (201), a picture truly in the great style; and the castled hill in "Bamboro'" (272), by J. McKissack, who has perhaps over-corrected his sky at the expense of luminosity. His "Wassemot" (38) is beautifully simple in its massing, and of exceptionally nice quality, but the subject is a little elusive—plain walls, a flight of steps and some dark blocks of stone upon which a woman stands—a highly artistic picture of nothing in particular, which everybody would like to possess. This is art for art's sake.

It is interesting to turn to the opposite method and see what charm of laciness H. Felton gets in his very pretty and elaborate "Sunshine and a Bridge" (251), or L. Misonne in his soft and almost too melting misty pastures. There is no doubt, however, that the mistiest, "Lumière Frisante" (202) is the best in some respects, for it is a truly observed light effect, and a charming subject of trees beside a little brook and figures on the path. A much firmer tone supplies the remarkable quality of T. H. B. Scott's "Bruges" (207), whilst in "The Towpath, Guildford" (199), by A. C. Banfield, we get the full strength emphasising the lines of a low bridge which are the motive of the design. Another river or canal scene by T. B. Blow, "A Relic of the Past" (252) is very engaging. Nor should "The Seine at Caudebec" (340), by Chas. H. L. Emanuel, be missed, which with "Honfleur—Low Tide" (342) will widen the scope of his work in public estimation. "In Lowestoft Harbour" (362), by G. Brown, should be recommended also for its splendid subject; likewise John Keene's "Polperro Harbour" (414), in which one thin sail puts the finishing touch to a good composition.

Fred Judge sends three of his beautiful oil transfers, "Holy Loch" (388), "The Pavilion—Night" (389), and "Moretonhampstead" (390), but he has not yet surpassed his first efforts in this method.

It is nice to see that C. Puyo contributes again. His works are "Le Bain" (44), "La Fontaine" (118), both of which are highly pictorial, especially the latter with its stone pine or cedar overspreading the well-head. The third "Vers la Source" (72) is perhaps less taking, pictorially, and some may think that M. Puyo's sharp and incisive lines, and clear cut tones, are overdone in this case. But I think this idea would be due to the environment of photographic tone, so frequently sodden, lifeless, and monotonous. M. Puyo works like an etcher. He delights in healthy "snap" and accent; and his method in no way sacrifices quality or luminosity; for the sky in "Vers la Source" is brilliant. Herbert Bairstow works much in the same style, and, as it happens, his "Sand Dunes" (260) is similar to the last in subject except that there is no Algerian water-carrier in it. But Mr. Bairstow has, perhaps, even more quality. He supplies a *liaison* between the needle-stroke etching-quality of the grass-tufts and the open light spaces. Thus he is able to bring his tones more naturally to the culmination of the brilliant glare of the sand, without missing any of the grip of the light and dark accents.

Francis Jay has always specialised in the nude, as an accessory in landscape, and here he repeats the process, having reduced his figures almost to disappearing point; so that "The Mermaids' Rock" (26) and "Styx" (166) are in reality landscapes, proper; and fine, wild rock scenes they are. But we are not without the nude as she is photographed, thanks to the Earl of Carnarvon, Nickolas Muray, C. A. Bromley, and others. The most fleshily nude is a print in red, which looks like a beautiful drawing, by C. Scarabello, "Nude Study" (50). The noble Earl's "Spring" (124) is a figure with an astral envelope, due to a soft-focus lens, which also makes the sunlight amongst the bushes very flecky and globular. But when one compares the identical subject at the P.P.A. shown by Bertram Park, done in a "tight' method, there is something to be said for his lordship's lens.

A few other figure studies demand attention and appreciation, particularly Mrs. Barton's original baby on its mother's lap, "Shadow Play" (145); J. Capstack's capital character piece "Alphonso Wing" (164); N. Muray's beady-eyed "Ruth Draper" (175), which mesmerises one; the splendid posing and arrangement of Lionel Wood's "Friends of the Footlights" (255) and G. Lynde's lady with downcast eyes called "Portrait" (258).

In genre work Janet Allan and Agnes Martin work in a clean, precise manner, and get truth and interest into their figures. They send "Scandal" (137) and "Fortune Telling" (257). Lewis A. Banfield shows an old Indian gentleman apparently carving his toes, "The Concentration of Sunda Singh" (221) "Le Lever des Petits" (329) is an animated interior, by A. Bologna, that reminds one of Van Ostade, and A. F. Kales places a figure of a musketeer very effectively in an archway in "The Cardinal's Guard" (384), though the livery is surely that of Louis XIII. not of Richelieu. A little earlier in history comes his "Lady of the Tower" (109), a mediæval person on a long, winding, outside stairway. A wonderful study of creeping light and depth of perspective in the shaded parts comes from Louis Fleckenstein. The figure here is that of a native standing "In the Patio" (181). Other outdoor figure subjects are three clever snap-shot enlargements by G. F. Prior, a market group "Idle Moments" (165), an ex-servicemen's band, "London Street Harmony" (214) and "Farringdon Road" (266), men at a book-stall. A splendid mob of orientals is sent by Capt. G. J. O'Brien, called "The Moharram" (313), and one of the best stage photographs I remember to have seen is Miss F. Vandamm's very clever "Columbine, Little Theatre" (353)

Architectural interiors scarcely exist, but J. R. H. Weaver saves the situation with his wonderful view "In Avila Cathedral" (110) which perhaps loses a little poetry by a too searching presentment of every feature.

Engr.-Comdr. E. J. Mowlam still supplies reminders of the war with his various battleship subjects, and even still-life is represented by two examples, Ranald Rigby's "Old Pewter" (12) and C. Lederle's "Fruit" (212). They both have fine quality, but the latter has the extra distinction of overcoming gravitation.

F. C. TILNEY.

A SOCIETY FOR STOCKTON.—A movement is on foot to establish a photographic society at Stockton At a well-attended meeting held last week, Mr. T. W. Kelley, president of the Cleveland Camera Club, delivered an address, and a provisional committee was appointed. Further meetings are to be held at the Adult School, Dovecot Street.

THE P.P.A. CONGRESS.

In the present issue we publish a further report of the proceedings of the Professional Photographers' Association's Congress which ended last Saturday with an advance private view of the exhibition of the Royal Photographic Society. Perhaps the fixture which was of chief importance from the practical standpoint was the demonstration of "Unusual Portraiture" by Mr. Charles Aylett, of Toronto, despite the fact that he had to work under conditions and with apparatus to which he was not accustomed. A report of this demonstration is unavoidably held over until next week. A short address by Mr. Herbert Lambert, of Bath, on the Wednesday afternoon underlined a point on which we have often written, namely, that many photographers who jealously guard what they think is a valuable secret are cherishing something which is universally known. Mr. Lambert mentioned that a photographer in a little town revealed to him, under the most solemn pledges of secrecy, that he had hit upon a wonderful new thing. The "new thing" proved to be Eastman Portrait film. Mr. Frank Brown referred to some of the unscrupulous practices which were adopted by some photographers in their efforts to obtain business on the strength of the reputation of established studios.

Mr. Pirie Macdonald's address on the Wednesday evening was a vigorous appeal for a wider interest in the intellectual pursuits of the time on the part of photographers and for a greater determination to realise their own ideals in their work.

The assistants' evening was a successful function, at which Mr. George Hana expressed the hope and his own desire that a way should be found to bring assistants within the Association. The president made all feel at home.

CO-OPERATIVE ADVERTISING.

At the meeting on the afternoon of Wednesday, September 13, Captain F. H. Wright, of the London Press Exchange, addressed the members on "The Co-operative Advertising of Portrait Photography." He said:—

Co-operative Advertising—What is it? What has it accomplished? Can it be used to promote professional portraiture? These are the three questions I propose to deal with as shortly and effectively as possible.

Co-operative advertising is the application of the principle of co-operation to the force of publicity. We all know the usefulness and power of modern advertising. It is part of modern life, and we are conscious of its suggestive influence all around us. A great authority on the power of publicity (Lord Burnham) said the other day: "Advertising is the key industry of the universe. It opens every door. It leads through the street to the market place, through the market place to the home. It is the fine literature of trade, and the illumination of business."

Now in America, many years ago, it was realised that there was in many industries a great deal of educational work that could only be done by the industry as a whole rather than by its individual members. The recognition of this fact led to the start of all those great co-operative campaigns, amounting to nearly 200, which are now carried on in the United States.

The fundamental idea behind a co-operative campaign is "the greatest good for the greatest number."

It calls upon the individual members of an industry to co-operate together, each contributing his share to a common fund for the good of the whole industry, to achieve a common purpose which, as individuals, they could not hope to do—indeed, in many cases, could not afford to do.

Most of these co-operative campaigns have been initiated to enlarge the market and increase the demand for some product. I will mention only a few—Apples, peaches, raisins, walnuts, oranges, lemons, grape fruit, cheese, eggs, milk and cranberries; manufactured goods include millinery, macaroni, woollen fabrics, linen, gas, granite, bread, bricks, books, bicycles, paint, linoleum, and even the coffin makers have banded themselves together—not, of course, with the benevolent object of increasing the use of coffins, but to educate the public to a right appreciation of the sympathetic and delicate service performed by the undertaker in the trying time of family bereavement.

This advertising of an idea or a service rendered by one portion of the community to another is no new thing in America. It carries with it a social service of the highest order. We find the printers educating their craftsmen to produce better printing, and the public to appreciate their efforts. The optical people have urged the importance of the care of eyesight. The paint manufacturers, with their "Save the surface" campaign, furnish a splendid example of educative advertising—the whole industry grouping themselves together for the purpose of teaching the community the protective value of paint. Bankers have organised themselves together for the purpose of inculcating the habit of thrift. For instance, our own Government are now spending thousands of pounds in just reminding people to buy Savings Certificates—thus proving the necessity of reminding people to do the most obvious things: and during the war it was found necessary to spend money in reminding people to serve their country in the time of great danger.

These illustrations—which I could elaborate indefinitely, had I the time—will give you some idea of the wide field covered by co-operative advertising. I cannot recall a single case where co-operative effort has been attended by anything but the most overwhelming success. The Californian Fruit Exchange—which was the pioneer of this form of advertising in the States—has nearly trebled the consumption of oranges since the start of the campaign. The consumption of walnuts has been doubled every three years, bringing them into steady use through every month in the year. And so on through the whole range of products so advertised.

Now to come nearer home. The first great co-operative campaign undertaken in this country was that great co-operative effort for which the British Commercial Gas Association was formed.

In a commercial way the problem of the gas undertakings of London and the provinces was not unlike your own professional problem to-day. Before the war the gas undertakings were making as much gas as the public appeared to want. They could not afford to advertise individually because the area any one company could serve was limited strictly by the area covered by its gas mains.

Further, it seemed impossible to increase the consumption of so necessary a product as gas. People used as much as they required and no more. If they wanted more it was there for them to use. They didn't want more. Nevertheless, the gas undertakings the country over formed the British Commercial Gas Association for the purpose of advertising the uses and advantages of gas for domestic and industrial lighting, heating, cooking and power.

It was a bold experiment, in which the organisation of the London Press Exchange played a leading part. Could you find any product more difficult to advertise than gas?—it seems doubtful, but it was done. And what has been the result? In spite of the fact that almost every new house that is built is wired for electricity, the consumption of gas is steadily rising. In 1918—far from a prosperous year, you will remember—the normal increase in the consumption of gas was accelerated by no less than 13 per cent.—an enormous figure for a commodity like gas.

Take the case of the Scotch tweed industry. Here an association of forty manufacturers of genuine Scotch tweed formed themselves into the Scottish Woollen Trade Mark Association, and advertised the merits of genuine Scotch tweeds, made in Scotland, of pure new wool. It was an attempt on the part of these manufacturers to protect their industry from the competition of English and foreign tweed manufacturers who had imitated the traditional Scotch patterns, but not their quality. There is no need for me to go now into the inner workings of these trades or their methods. It is enough to say that the advertising has been astonishingly successful. So successful that Scotch tweeds have become definitely the fashionable thing to wear for the past two seasons. You have never seen so many Scotch tweed suits and overcoats and women's coats and skirts worn before.

Again, this year, largely through the instrumentality of the London Press Exchange, the British-Grown Tomato Industry embarked upon a considerable advertising campaign to increase the consumption of tomatoes. Again it is a prosaic commodity that was advertised. Let me tell you that one single advertisement in that campaign produced no less than 14,000 requests from the public for tomato recipe books.

Post-war conditions have brought new problems, and individual members of industries have found themselves faced with entirely

new difficulties—shifting values, restricted trade, and in some cases the total disappearance of hitherto profitable markets. Where the problems are common to the industry as a whole, the remedy is to be found in co-operative action by all the members of the industry. More especially is this so where the object is to enlarge the market and to create new consumers. It is not surprising that in many industries leaders who have courage and wideness of vision find themselves turning to co-operative action for the purpose of solving the pressing problem of the age. If the war has taught us nothing else, it has taught us to recognise our interdependence upon each other, and the value of unselfish co-operation for the common good.

However, enough has been said of the value of co-operative effort as applied to advertising, and the question arises—Can you make use of it in your profession—is it wise or right that you should do so?

What is your problem? It is that not enough people are having their portraits taken. It is a big question, and on its solution depends the prosperity of your profession as a whole. Yet the answer is of the simplest, and can be put into very few words. It is that people simply do not think about it, and no one ever reminds them. And they are hardly to be blamed for forgetting it.

Life is now so complex, so many are our necessities and needful luxuries, so insistent are the cries to buy, to buy—that it is not so strange that it should only occur to the average person once in ten years to have a portrait taken by a professional photographer. At the moment I can only think of one time in the life of the average individual when he is seriously reminded of the necessity of portraits—and then it is brought home to him in a rather melancholy way—when he realises for the first time that someone dear to him has passed over without leaving behind him a solitary portrait of himself.

I suggest to you that if the public were steadily and consistently reminded, not of individual photographers, but of the desirability of having their portraits taken, I think you would find you have solved your problem in a simple and dignified way. The advertising must of necessity be collective—must be done skilfully, with dignity and restraint; that is the only way advertising can be employed by your profession.

And now you will want to know something of the cost of the right type of campaign for your purpose.

At a fair estimate, there are 8,000 professional photographers in the country. There may be ten, but we will accept the lower figure of 8,000. Supposing only a portion of that number have sufficient courage and breadth of vision to perceive the possibilities of this scheme: say 4,000 professional photographers from whom we may confidently expect contributions. Naturally the big man with a big connection or following should contribute more than his smaller brother, since he will be likely to derive greater benefit from the advertising. It is proposed, therefore, that the contributions should be either £2 10s., or £5, per head, per year, according to whether the rateable value of the contributor's premises exceeds or falls below a certain arbitrary figure to be fixed later. We may suppose that of that 4,000 contributors, 75 per cent. will fall below the figure mentioned. That would give us 3,000 contributions of £2 10s. and 1,000 contributions of £5, making a total advertising fund of £12,500. Large as this amount may appear to be, it is none too much to carry out such a campaign as you will require.

Then you will say: All this will be to the great benefit of manufacturers of photographic materials. Well, gentlemen, the manufacturer is first and foremost a business man. And when you, as the authors and controllers of this scheme, approach him and invite him to give his help, I believe it will be forthcoming, and in no half-hearted fashion either. If the manufacturer, by according to such a campaign liberal help, is going to make success certain beyond all doubt, he will do it and do it quickly. I will give you an instance. In America the Kodak Co. have been themselves conducting a campaign in the Press on similar lines to the one we have suggested in our booklet. It has been a great success, and local professional photographers all over the States have taken advantage of the national scheme by linking up with it their own localised advertising.

Consequently, it is inconceivable to me that there is any doubt that you would have the strongest support from the manufacturers of this country.

In conclusion, may I suggest the best method which our long experience has taught us is the right one to employ in the starting of a co-operative campaign by an association?

First of all, you should, as an association, at the largest meeting possible pass a resolution in favour of a co-operative advertising campaign; that a scheme be adopted, and the funds raised forthwith. This being agreed to by the meeting, you should, then and there, appoint a small publicity committee of businesslike men, investing them with all necessary powers and authority to proceed with the launching of the scheme.

It is necessary and advisable at the start to appoint the best firm of advertising agents that you can find for the purpose of carrying through your scheme. It is essential that your advertising should be planned by a firm with great experience of co-operative campaigns—one which is accustomed to bearing in mind the fact that the interests of a whole profession are concerned, and that the funds to be administered by the Publicity Committee are in a sense public funds, and must be expended with wisdom and discretion and with due regard to economy: in other words—in the best interests of every member contributing to the fund. I might also add here that if the advertising firm has, in addition, a knowledge of the photographic business and the advertising of photography, it will be of undoubted advantage in working the campaign. For instance, the London Press Exchange, in its long association, extending over twenty years, with Messrs. Kodak, Ltd., as advertising agents, have naturally gained a knowledge and experience which would prove of inestimable benefit to you in the prosecution of your own campaign.

There is just one more point I should like to touch on, because it is always the subject of a question in the starting of these campaigns, and that is, what do the advertising agents make out of it? The remuneration which the agent receives is a fixed commission paid by all the newspapers and billposting contractors throughout the country, and is only paid to properly accredited agents—it is never paid to anyone else. For this remuneration, we do all the work of planning and carrying through the campaign, and indeed, do a great deal of the heavy organisation work necessary in starting a co-operative campaign. In the first years of a campaign we have found, as a rule, that the amount of work we are called upon to do is usually out of all proportion to the remuneration received. This does not trouble us, for, convinced of the essential soundness of the scheme, we are content to take the long view and await the development which comes later for a fair return for our early labours. The administration expenses of a campaign such as yours will be infinitesimal, and so far as the advertising is concerned you can assure your members that every penny subscribed for that purpose will be so used.

If you decide to embark upon a campaign for the good of your profession, I prophesy that, providing it is conducted properly, you will reap a well-deserved success. You possess the knowledge, the enthusiasm, and indeed, the profession as a whole is imbued, to my mind, with a rare and precious vitality; and were it not so, such an exhibition as this could never have been brought into being.

One outstanding result of this campaign is inevitable. It will have the result of immensely strengthening this Association and increasing its membership, and as the campaign develops and the advertising appears, the co-operative effort so displayed will not only create an added bond of fellowship between you as members, but the advertising itself will be a source of pride to all the craftsmen who stand behind you and who play a part, however humble, in the production of the works of art and beauty which are so essential a part of our social life.

In the discussion which followed Captain Wright's paper, the Chairman suggested that the matter be left to the Council to consider and report.

A member pointed out that as subscriptions would be optional, those who did not contribute would equally reap the advantage.

Mr. T. Bell, in reply to the Chairman, said that the number of photographers in the United Kingdom was somewhere between 8,000 and 10,000.

Mr. Marcus Adams suggested that those in the room who were willing to subscribe £5 a year should hold up the hand. He also suggested, as a means of discriminating between the big man and the little man, that 10s. a year be subscribed for each assistant employed.

Captain Wright, in reply, said that the suggestion with regard to the non-contributing people who received an equal benefit cropped up every time. There was nothing in it at all. Here was a clear-cut proposition which was going to be for the good of the whole

industry. The people who did not come in could quite well be ignored. These people would gain financially, but they would lose morally. In every trade and profession there were a sufficient number of clear-sighted and unselfish men of vision who were prepared to start such a scheme and make it go.

After some discussion as to the value which any resolution of the meeting might have, the simple proposition that the scheme be referred to the Council, who would report upon it to the members in due course, was put from the chair and carried by a show of hands, apparently without dissent.

On the Friday afternoon, after the Statutory General Meeting, a lecture was delivered by Mr. Hopton Hadley, also on the subject of "Co-operative Advertising." The President occupied the chair.

Mr. Hadley said that he preferred to call his address by the title, "A Scheme for Bigger Business for British Photographers." Now that the Association had attained its majority there was man's work ahead of it. Everyone was aware of the fact that conditions of business had greatly altered, and these changed conditions called for changed methods. He would suggest as a motto of the new era, "Each for all, and all for each." No particular individual could do very much to extend the public appreciation of professional photography, but, in combination, work could be done which would be really full of results. He alluded to some wonderful work which had been done by co-operative advertising to create prosperity in other trades. The first example was that of the Californian fruit growers; the raisin growers alone in California this year were spending many thousands of pounds in advertising the season's crop in the United States. The co-operative effort of the Irish linen manufacturers had had a very successful issue, and he believed the same was true of the Scotch tweed manufacturers, the tomato growers, and others. In the States a florist conceived a very effective slogan: "Say it with flowers," and out of that simple and poetic expression quite a large concerted movement among florists had developed.

The profession of photography existed not on sentiment alone, but on self-esteem, and to bring about the proper psychological attitude on the part of the public called for co-operative movement; it was more than one photographer could do. The wonderful thing about co-operative advertising was its small individual cost. The tomato growers secured their results with a contribution of one-twelfth of a penny per pound sold. The method of raising the money was the main problem, and he was indebted to Mr. Marcus Adams for the practical suggestion that there should be a contribution of ½ or 1 per cent. on all one's trade purchases. Having agreed upon that part of the programme, why should not the manufacturers be got to contribute a like sum? This would make the ½ per cent. into 1 per cent., or the 1 per cent. into 2 per cent. A fund of £4,000 or £5,000 would do wonderful work. The splendid press notices of the present exhibition were a kind of foretaste of what might be achieved. A part of the programme might be to have provincial exhibitions of the works already shown in London. He had noticed a reference in the Press to "the new fashion in photography." Whatever the new fashion might be, it was helpful to them as professional men. A new fashion should be created each year if possible. Shakespeare spoke of the seven ages of man, but how much would each person present that day appreciate a series of photographs of himself taken at more frequent intervals than those separating the seven ages! He also suggested active measures to create business in connection with the Christmas festival. Why not a co-operative effort to introduce the custom of photographic Christmas cards? A few well-chosen papers as the media for advertisements would work astonishing results. He mentioned especially the illustrated daily and Sunday papers, which were read so largely by women. A regular Press campaign, supported by judicious and timely paragraphs, might be instituted, and connected up with bulletins in the studio window. His purpose that day was simply to familiarise his audience with the idea of co-operative advertising for the individual and the common good.

Mr. A. Barrett asked whether Mr. Hadley considered that all exhibitors should notify their local Press of their exhibits; also whether it would be possible for him to work out some kind of scheme for the consideration of the Council, the scheme to include various advertising methods, through the Press and by means of the shop window.

Mr. Mills asked whether it was really possible to raise sufficient money to advertise to any appreciable extent. The lecturer had mentioned the possibility of getting up a photographic boom at Christmas time, but what was wanted was some means of enlivening business in the spring and early summer.

Mr. A. Bennett asked whether the lecturer favoured hoarding advertisements?

Mr. Hadley, in reply, said that he thought the exhibitor who did not try to get it mentioned in his local Press that he had had pictures accepted for a London exhibition was wanting in enterprise. As a rule, the local Press was only too pleased to publish the fact that a townsman had obtained any distinction. He wished to make it plain that if this co-operative movement were entered upon by the Council, specimen advertisements, window bulletins, and show cards would be first submitted to them. Nothing would be done without the Council's approval. Mr. Mills had questioned whether it was possible to raise a sufficient sum of money. But even a small amount would do for a beginning, and as experience was gained, and results became evident, larger amounts would be secured. There was a possibility of getting larger donations from wealthier members of the profession or from the manufacturers. One effect of the scheme would be largely to increase the membership of the Association, and to double the membership would be no small result; but beyond this, there would be very large increase of individual business. Advertising was unlike any other kind of seed-sowing, for it could be sown to harvest at any time one pleased. As for hoardings, he was not in favour of them. They were the special medium for goods that were sold at every small shop, and photographers needed to create, by more subtle methods, a public appreciation of their work.

A hearty vote of thanks was accorded to Mr. Hadley.

ADDRESS BY MR. PIRIE MACDONALD, OF NEW YORK.

On the Wednesday evening of the Congress Week the chair was taken by Mr. R. N. Speaight, who, in introducing Mr. Pirie Macdonald, said that his work as a photographer of men was world-famous. But although his work was of the highest artistic character, he also held to his record the highest number of awards ever given for technical photography in the United States, if not in the whole world. That was the backbone, the speaker believed, of Mr. Macdonald's great success.

Mr. Pirie Macdonald, who was enthusiastically received, said: I am glad to have so sympathetic an introduction. A while ago a man introduced me who knew nothing about me, and he handed out a reel of stuff which made me realise how difficult it would be to impersonate my reputation. (Laughter.) But our friend, Speaight, has been kind, and has put me down as what I am—just a workman. I have no other claim to any celebrity whatever, except that of a workman.

In talking to you to-night I want you to realise that I am talking to those who are of my own kind. I am talking to the middle-class of our people. I am talking to you not as Britishers, but as though I were talking to a set of Americans of the kind that I have sprung from, with the idea of trying to give you a bit of the result of the experience of life that I have had. And I am not going to preach.

I have a strong feeling that only a short time ago we were going very wrong, that we all found ourselves deeply involved in business —desperately involved in business. And we were people who were making a claim before the world as artists, and the business was occupying all our attention. Time was when, all through photography, with you as well as with us, we found ourselves so involved in the necessity for money that we were doing many things in an abominable way. It was due largely to the fact that we—the whole world—had grown to a rut where we had lost the essential facts of freedom. We in America, and you in England, were in exactly the same boat. We got to the place where we did not ask friends at night in to have a snack; we were not content with a little beer, some cheese, and a pipe. No; it would not do. It was a condition of mind, and if by chance what I happen to say does not fit *you* in detail, change it to your own key. Dinner was at eight o'clock, and we had to put on "glad rags." If we did not, our neighbours would feel that we were not quite fit. And we got so that wine was necessary instead of beer. We got to a point where we taught our cooks, and, when we should have been glad if they had known how to broil a chop properly, to do things with French names. Instead of plain water on our tables we had Perrier or Apollinaris. We got to a place where, unless we sported a car—I am not speaking of owning a car, but of sporting a car—we were not quite fit to associate with people who did. And many of us were not able to afford the car we sported. Then we went on, and, you know it as well as I, in England we went on to hotels that were filled with German waiters, instead of stopping at

the little, old wayside houses where we used to get a meal off the joint for two-and-six. Oh, no, we had to go to these palace hotels because they were the proper place for a motor-car to draw up against. So we found the whole thing going on and on, and harder and harder, and faster and faster, and the trouble was, you know, that we were doing things we were not quite fitted for. (Applause.)

The real and essential trouble with this life that we had been leading was that, as professional men, it made us do things we should not have done. The overhead and the upkeep of our houses were greater than we had capacity for handling. There are here men who are captains of industry, and I am not talking to them; I am talking just to the ordinary type of man that I myself have come from. Many of you, like me, had originally only a bit of talent, and we found that as we enlarged our establishment it was necessary to work faster and harder. After a while, because we had this larger establishment, we had to do things that seemed not quite legitimate in order to keep the place filled. We had to work all the time. And that meant that we were turning out things that did not have the love in them. That is what I mean, and when you do not have time to stop and put love in what you do, you don't have freedom. The only reason I am here to-night is to give you the idea that there is more in freedom than there is in anything else on earth. I think that photography needs an awakening to the fact that many of us are not free to do what we want to do. There are many of us that have not had the chance to do the work that is worth while. There is many a man here who knows that since he has become successful in the eyes of the world he has had no time to hear music as he wanted to. There is many a man in this room who has never been in that marvellous storehouse of the treasures of the world that you have in Trafalgar Square. There are men in New York who have never been in the Metropolitan Museum of Art. Many photographers who buy gas for two motor-cars never feed their souls. They are doing degrading work. They are not doing things that have the divine in them. It reminds me of a sign that was on the wall of the little tailor's shop near the railway station: "Leave your clothes for pressing on the way to business, and call for them on the way home." (Laughter.) That man merely expressed the whole tendency of the time. The absurdity of it did not strike him. He merely wanted to get into the minds of passers-by the fact that they were in a dence of a hurry, and that he was the man to assist them. That same kind of absurdity has gone on in our places. We have been doing exactly that kind of fool-stuff because we have been crowded overhead, and because down underneath we were dissipating our money, which meant our energy.

Then came the war. The most carefully devised schemes for the continuance of this foolery of ours were shut up and gone. In an instant society was re-arranged. People dropped out who had been long on our level, and other people came and stopped for a minute or two on that level, and either stayed with us or went on to where they are now making themselves absurd. But one thing the war did in the way of good—and it did very little—(hear, hear)—for we find that international law is in ruins; but one thing good that it did was to give us a chance to stop and review the thing coldly. We were divested of our business, of our usual interests and habits, and the opportunity to pursue them. Some people stopped; other people merely bated their breath for a minute or two until the tide came in, and then they started in on the same thing again. What we should have got out of that pause was to take that which was good that we had in this former life of ours, and leave behind those things that failed.

The worst blunder of the pre-war days was the assumption that education was merely a means towards material prosperity, that anything that was worth acquiring should be capable of being turned into pounds, shillings, and pence. It was the worst blunder we made. I do not want you to get the idea that I believe all these creature comforts to be traps of the devil. But I do mean that the price you have to pay for them is sometimes too high.

There are two kinds of photographers. The first are those who really know how to do things, who have the basis of technique, the culture, and the capacity, and the second are the "bag of tricks" men who have only a few little stunts. You can expect one of the latter to want to turn his tricks into pounds, shillings, and pence, like a showman. But it is the other kind of men I am talking to. It is the other kind of men who are in danger to-day of getting under the ceiling that is too low for them, and always having to bend their neck to the requirements. The trouble was that, owing to the necessity of the case, our education became a something that was not real, that was not cultural; it became too thin. It got so that portraitists in their hurry would mistake characteristics for character—if you know what I mean. The genuineness which prompts a man to make great portraits was taken away by his desire to keep his head financially above water.

It looks quite a lurid sort of picture in retrospect. The trouble was that people, instead of wanting to know the hearts and brains of men, were always asking for some knowledge about a photographic process that could be turned into money. Instead of wanting to know what the man was, in order that they might be able to put down that which was essential and true, they found only time to look at the outside of his face, and if they could make a good map of that and could sell it, it answered. You know that that is far from being the best that we can do.

You will say, "Well, what about it?" Only this: we have got the chance of beginning over again, and before things become too involved again, before business gets too big again, before we overreach ourselves again, to get time to acquire culture, to get time to live up to our own ideals, and not those of our neighbours. I could shriek that at you, not the ideals of our neighbours, *but the ideals that are our own.* (Applause.) How are we going to do it? It means, of course, starting at the bottom and cutting down living expenses in order that we may be simpler. That does not mean just going home and taking it out of the wife. (Laughter.) That is not fair; it is not the thing to do. You have to play fifty-fifty with the old girl! It is a thing that has to do with your soul; it is not a matter of money merely, not a matter of saving some more money, or of preventing some money going. No; it is something that is to bring about ultimately your freedom, and you have got to have a square deal at home. And she will help you. It means the reduction of the extravagant end of your studies. I am speaking only of those things which you are incapable of actually handling and seeing yourself. It means the keeping down of "overhead," so that you get the time to think. How many of you, I wonder, really do take off a bit of time in which to do the kind of work, whether it will sell or not, that will satisfy your own soul. I am spending more time away from my business than I used to do because I am getting older, and I have other things. It happened that I was out in the woods and left alone for three days while my friend and the guides went down the river. I was thinking over and writing the headings of this talk—thinking it over link by link—and when I came to this, "Did you ever take time to do the thing you prefer to do, make the picture you want to make?" I replied, "Yes, I do, or why should I presume to talk to other people about doing it?" But the joke was this: I have got a kiddie, the dearest thing that lives to me, and I have not been taking the time off that I should have given to her. If you have got kiddies, give them half-an-hour a day. See them, learn to know them, and get the honey there is out of life! (Applause.)

Take the time to do those things you prefer to do, to read what you prefer to read. The majority of photographers, unfortunately, have not read—and are always apologising for the fact that they have not had time to read the things they ought to read; and I want to call your attention to the fact that we, inasmuch as we handle all types of men, have at times to handle people who have read, and you cannot expect to get from those people what you ought to get unless you are their peer in culture—unless you know the kind of things that they are accustomed to think. You cannot divide such a man from his own class and particularise him, you cannot know him unless you have read the kind of stuff he is accustomed to read. There have been people who have been born with more of the silver spoon than we have, whose start in life was on a plane above ours, and who, accordingly, have gone farther; and it is our job to be up there with them, so that we can meet them eye to eye and weigh them. If we are not able to weigh them and put them where they belong, how are we going to justify taking the money for the portraits we *allege* we are making of them? I was talking to half a dozen photographers here the other day, and I asked them if by chance they had read what to me is the most wonderful piece of compilation and reduction that has been written during this century—H. G. Wells's *Outline of History*—and I found that not one had read it. I was sorry, because it is a book worth reading. It is a book worth reading, because it will put you on a footing so that there will be understanding, and when other people talk about things you will not have to mumble and pretend you understand it. I wonder how many of you have read Barrie's *Courage*, the address delivered at St. Andrew's, on May 22. Few, I presume. But it is a gem that is rare, and other people are going to know about it. In any event, if you have not read it you cannot engage them on that subject, and it is a little thing that is so well worth reading that if by chance another man has read it, and you

MEMBERS OF THE CONGRESS OF THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION, HELD SEPTEMBER 11 TO 16.

PHOTOGRAPH TAKEN ON SEPTEMBER 14 ON THE EAST TERRACE, WINDSOR CASTLE, BY SPECIAL PERMISSION OF H.M. THE KING.

A Key and List of Names identifying the members in this group are in preparation, and will appear in next week's "British Journal."

have read it also, you will be able to get the fire in his eye. How many of you have read that nasty book, Upton Sinclair's *Main Street*? It is sordid as any book ever was, but it is a book that everybody in England should read, because it has its parallel in England to the sordidness which it describes in America. It is not the America you would meet if you went there, but it is worth reading.

Of course, this is not a matter of reading some specific things: it is a question of keeping yourselves intellectually alive and abreast of events and of the thoughts of men. If we are to stand as we should before our clients and meet them on the level; because you cannot make pictures from far underneath, and have them without distortion—you have got to put yourselves up, and the only plea I am making to-night is that you do not let yourselves slip back into that life the ideals of which are merely competition with your neighbour in the matter of showing that you have got money. Compete with yourself. Give your family a chance. Let them know that the next generation has got to be a family that meets higher people than you can possibly meet by right of intellect. I am not speaking of birth or fortune. The true British democracy is of the mind and of the heart. After all, what I have said is only a plea for absolutely genuine moral earnestness. You cannot reach the goal all at once, but you can go a bit of the way if you only desire it hard enough. Your destiny is the child of your desire, but bear in mind that the father of destiny is always the will. If you don't desire it hard enough to go and do it then desire is merely a picture and a fiction.

Over in New York they are building a cathedral—a presumptuous thing to do in New York. But they are building a cathedral that some day, with the mellowness of time, and through the richness of human offering, will be a great temple. The story is told of a man who went up and saw the masons at work, and he said to one of them, "What are you doing?" The reply was, "I am cutting stone and getting ten dollars a day for it." He went to another man, "What are you doing?" "I am cutting stone for ten dollars a day, and only eight hours' work." And he went to a third man. "Well, friend, what are you doing?" "Me?" was the reply. "*I am building a cathedral.*" (Applause.) I feel that it is worth while to build cathedrals. When it comes to a new way of turning sixpence into half-a-crown, there are people who are much better able to tell you about it than I am. I have been fortunate enough, in spite of myself, to accumulate some money. I have been at it, it is true, nearly forty years, from the day I worked my fingers to the bone cleaning my floors and thus saving the price of a charwoman, which was two "bob" a day. I have got a little 3B Dallmeyer lens in the safe at home. It cost 84 dollars, and I bought it thirty years ago or more. That money came through doing that charwoman's work before I opened my shop in the morning; it was my own shop, I was on my own. While I had been working for other people I had been accustomed to smoke a twopenny ha'penny cigar after supper. I cut that out because I wanted the lens. I wanted the lens because I believed it was going to help me better to interpret. To me to-day that lens is a sacred symbol. It meant sacrifice. But this kind of thing does not end merely in sacrifice. It carries one along a road which has in it much elation. All through my life, whether people bought them or not, I have made in the set of the proofs a something that was the best I knew how to make, and you would be surprised to know how many of those better things people did buy. (Applause.) I was surprised, too. I said to myself, "These are things that are going to be bizarre to the people to whom I am selling pictures. Even if the man himself likes them, his wife will not." But the world is tremendously good. It does appreciate us much more than we imagine that it will.

So I kept on crowding myself all the time, and never leaving for an instant the idea that the man behind his face was the man I had to learn to know; the man behind his face was the man I had to be able to invite to the outside so that I might put him down, that his friends and his family might have him when the evil day came. One of the keen satisfactions I have is to know that all through the war, when our youngsters came to New York, they received wires from their homes in distant parts of the States, "Go to Pirie Macdonald before you leave." And they did come to me. I had then sufficiently devoted myself to the idea of getting that which was behind a man's face that these poor youngsters, some of them sick and nervous, some of them rigid with determination to do that which they knew in their souls they were affrighted to do, were read by me, and I was able to unfold better those kiddies than if I had not so worked. I felt that all my previous labour was paid for when I was able to do that. That was one of the few things in my life which really did pay. Widows and mothers have since come in in black, and I have never found it necessary to put my elbow before my eyes. I have gone out to meet them, knowing that I did all that I knew how to do that day. (Applause.) I might have done it better the day before or the day after, or another man might have done it better. But, friends, I want to leave with you only this. There is a job for you to do. British photography, American photography equally need an elevation. It is not a question of a trade council which was going arbitrarily to bind a man that he must not sell under three guineas a dozen. No; the elevation is to come from within yourselves. I want to leave with you the idea that you are to do each day—every day—the best that you know how to do that day. Thank you. (Loud applause.)

The chairman said that it was his business to finish Mr. Macdonald's lecture. Mr. Macdonald had shown them only one side of his life. He was known to them as a great genius, but he was also a great friend. Last year he (the speaker) made the confession to Mr. Macdonald that he was not doing the work he wanted to do, that there was something in it which was mechanical. And this great man, while on holiday, with little time to spare, devoted three and a half hours to the instruction of a brother photographer. He did not just talk; he actually took off his coat. During that three and a half hours he taught him what he had never learned before. When Mr. Macdonald came over this year he exacted a promise from him (Mr. Speaght). It was that once a month he should make a picture which did not mean bread and butter to him, that this should represent the very best that he could do; and then, by the time of the next exhibition, he would have eleven or twelve pictures made at his leisure, of which he could be really proud.

Mr. Swan Watson, in proposing a vote of thanks to the lecturer, said that while he could not agree with some of the things (not relating to photography) which Mr. Macdonald had said, he had felt the lecture to be most inspiring. He had touched upon the innermost things in their hearts. He had reminded him of Huxley, who wrote in his notebook on his child's birthday, "I will do the best scientific work from this day, no matter whether I may be recognised or not." Mr. Macdonald had touched on the question of the photographer's education. He believed that the future photographer must be a better educated man. Possibly in the future a photographer would send his son (intended for the same profession) to a university to study psychology, fine art, method, chemistry, and optics. Even those of them who were past the age at which they could expect to enter for a university degree could keep their minds active and add every day to their deeper knowledge. He had himself attended this year a class in optics and chemistry, taught by a man much younger than himself, and he had never had a more enjoyable time.

Miss Brownlee, of Bristol, seconded the vote of thanks in a graceful little speech. None of them could have listened to Mr. Macdonald, she said, without being moved, and they would all go out, not only better photographers, but better men and women for what they had heard that evening.

The vote of thanks was enthusiastically accorded, and, in reply, Mr. Macdonald said that this vote of thanks was in a line with the kindness he had always received in Britain. He believed that they were beginning an era of glorious years—glorious in the degree in which they made them glorious.

A PHOTOGRAPHER AND HIS ASSISTANTS.

Mr. C. P. Crowther's lecture, "The Man Behind the Camera," to the Congress on Tuesday in last week resolved itself into an amusing interchange of argument and badinage between himself, the Chairman (Mr. Marcus Adams), and members of the audience on the ethics of the use of the master's name on productions which were mainly the work of his assistants. Mr. Crowther began by exclaiming strongly for individualism, which meant, he said, the absolute overthrow of tradition. In his characterisation of various one-man photographers he made one or two members of the audience blush, and one (Mr. Herbert Lambert) even run away, at his rather thickly sugared compliments with regard to their individualistic work. Of Mr. Furley Lewis (who was present) he said that the lovely nature of the man came out in his work and in his life. He was a man for whom nobody in the world had an ill word, and he was the supreme example of a one-man photographer, who did everything himself, even to carrying the prints to the post. Mr. Crowther urged that photographers who exhibited should send to the exhibitions only their own individual

work. He sympathised with the plea that in business it was necessary to make the pictures which the client demanded, but for the sake of the photographer's own reputation or his own satisfaction with himself, when he sent to an exhibition he should send something which was his own production entirely, and which was done to gratify not his sitter but himself.

The discourse was interrupted here to admit of the lecturer taking breath, and Mr. R. N. Speaight availed himself of the opportunity to disagree with Mr. Crowther in certain respects. If a man was going to be a successful photographer he simply could not do the whole work himself. He was ready to admit that the ideal was a studio for one man who should do everything, but financially this was not practicable, at least not in London.

Mr. Crowther replied that he had been talking not business, but ethics. Had a man a right to sign a picture with his individual name when it was not entirely—perhaps not at all—his own work? This was one respect in which photography suffered in comparison with painting. The photographic result was brought about through the agency of perhaps four or five persons at different stages of the operation, whereas in painting the one man completed everything with his own hand. The ordinary studio photography, carried on in studios where several assistants were employed, he described as mill or factory photography, and everything was quite as it should be if only the name of the firm was "The —— Studios," but if it was the name of an individual which was placed on the prints, he thought that it had no more right to be there than to be on a cheque when there was not the money in the bank.

Mr. Speaight agreed that pictures from a studio, when exhibited, should bear the name of the operator, and that was the case with some of the pictures at present in the gallieries from his own studio. Mr. W. Illingworth was of opinion that whoever showed a picture for exhibition should personally print it, mount it, and deliver it. Miss Weston pointed out the fallacy of a comparison with the painter who, perhaps, got £150 for one picture, whereas the photographer got three guineas for a dozen. Mr. G. W. Futcher said that it was commonly supposed that a portrait done by Reynolds was three-fourths the work of his assistants. Mr. Marcus Adams said that he employed assistants, but he felt it his duty to lead them, and not to let them lead him. In many firms the assistants dominated the masters—not on the commercial side, but in the actual production of the work.

Mr. Crowther then resumed his lecture, and again declared against tradition. Tradition was a handicap. When the revolt came we should see quite a different world of light and colour. Tradition had no value. It was negative, retrospective, and retrogressive. The past was dead. Nothing could be achieved if we were manacled to yesterday. It was only by a refusal to accept tradition that we could hope to evolve new and better portraiture.

Mr. Herbert Lambert took exception to this. There were traditions in the past which should be studied, and the finest work now and in the future would be based on those traditions. One had to discriminate between traditions and what were mere passing fashions; but he believed that photographers had a great deal to learn from the old painters with regard to the tradition of lighting.

Mr. Furley Lewis, in reply to a call from the Chairman, said that as his name had been mentioned he would like to say that his only reason for being a one-man photographer was an entirely selfish one—he enjoyed every bit of his work.

Mr. Swan Watson uttered a genial protest against the forcefulness of language which some speakers had used on that occasion in putting forward their views, imitating, apparently, a speech by a distinguished visitor the previous evening. He was old-fashioned enough to believe that in connection with photography there never arose any occasion when such expletives were necessary; they should be reserved for much more important occasions. With regard to the bone of contention which had been cast into their midst, he reminded the Congress that both Michael Angelo and Raphael employed many assistants, and their masterpieces were largely the work of such assistants, although they were universally credited to the masters.

Mr. Crowther having apologised on behalf of some speakers, and also possibly on his own behalf, for having let slip some forcible and picturesque expressions, which, he said, were uttered with no thought of anger, but only for decorative purposes,

Mr. Adams closed the discussion, remarking that it had been a most interesting afternoon. He still disagreed with Mr. Crowther. If he designed a building it did not mean that he was going to lay the bricks, and yet surely the credit of that building should go to himself.

ASSISTANTS' EVENING.

On Thursday evening the assistants gathered at Prince's Gallery by special invitation. The invitation was accepted in surprising numbers, and a thoroughly enjoyable evening resulted. Much of the success was due to the fatherly manner of the President, who won instant popularity among all the young people, especially the young ladies. The various members of the Council were also well in evidence in seeing that the guests gave adequate attention to the good things in the exhibition, and also that they were replenished in the inner man—or woman. There was very little that was formal about the proceedings, and after a brief lecture or two the company broke up into groups and were taken round among the portraits by various members of the Council. Subsequently they met again in the Congress gallery, when a flashlight photograph was taken, and the result of the window and showcase dressing competition was announced. The judges gave ten marks for selling value, five for general attractiveness, and five for genius and novelty in arrangement. The first prize of two guineas went to Mrs. Tucker (employed by Angus Basil), the second prize of one guinea to Miss Kirby (employed by Gordon Chase), and an extra prize of one guinea for a showcase to Mr. Bates (employed by F. G. Wakefield). The successful prize-winners received their awards amid loud applause, and with some excellent remarks from the President on the value of the guinea.

Subsequently Mr. Bamber, of Blackpool, offered a prize of ten guineas for the best account of the assistants' evening, and Mr. W. Illingworth, of Northampton, immediately offered a second and a third prize, respectively, of two guineas and one guinea, for such essays.

The customary vote of thanks, moved by an assistant in the body of the hall, had added to it a recommendation that the assistants' evening be an annual function, and this was adopted, amid loud applause.

Assistants as Associate Members.

Mr. George Hana, a member of the Council, addressed those present on this subject. He said that he wanted all the assistants to come into the Association. He believed the Association would be strengthened by an associate membership of assistant photographers. He spoke only for himself, not for the Council, nor for the Association. For his own part he wanted them all in. It would be for the benefit alike of the Association and of the assistants. The Association had been twenty-one years in existence as a masters' association. It had done good work, alike for the individual and for the whole profession. The evidence of that was on the walls of the Exhibition. He could safely say that such an Exhibition would have been impossible twenty-one years ago. How far it might have fallen short had not the influence of the Association been there to help it forward he was not prepared to say, but he had not the slightest doubt that the Association and its counterparts in other countries had had a broadening and enlightening influence on the general body of photographers which made for better work. He believed that never before in any country had a better photographic show been exhibited. He wanted to see them all members in some form or other. Those of them who had ambition would find it stimulated and given more opportunity within the Association.

The Association, although a masters' association, had not ignored the existence of the assistant. Many years ago it formulated a scheme for giving the assistant a status; unfortunately that scheme was years before its time. At the present moment the "Record"—the very latest expression of the Association's activities—had a plan for bringing together employer and employee, which it was quite possible in the future might be of very great usefulness. He saw no point at issue between these two bodies of masters and assistants. Both bodies could be members of the Association with equal advantage. The Association had no limits or restrictions to its energy. Its whole aim and object was the betterment of photography generally. He could conceive no line in pursuing that object which would be adverse to the assistants. He would like to see them all members, and that was all he had to say; he had no cut and dried scheme, but it would help the Council to have some opinion from the meeting.

In reply to a member of the audience, who suggested that the

Council should seriously consider the question and formulate a rough scheme and then call together a sub-committee of assistants, and afterwards another meeting of assistants to lay the whole scheme before them, Mr. Hana said that the Council had it already within its discretion to do this, but it was desirable to get more definitely the feeling of the present meeting than such a suggestion conveyed.

Asked to define "Associate," he said that under the articles of association there was a clause defining associate membership, and any proposals would have to conform to that clause. The annual fees and other details would be determined by the Council. The Association already had powers to take in associate members. The scope was very wide, and the articles had been framed with a view to bringing in everybody whose influence could be of value in furthering photography generally, though he thought they would stop short of bringing in the amateur.

An assistant expressed the view that the time was not yet ripe. He was pleased that some member of the Council was considering the assistant's side of the question, but the obstacle was a want of confidence, which started right down in the workshop. He himself had spent many years as an assistant, and had worked for a number of employers, and he had found generally that there was not that confidence between employers and staff which one would like to see and which would serve as a basis for working together in an association. The position of the employee was always that he wanted more money and shorter hours, but photographic employers—perhaps it was not peculiar to them, but they were the only ones of whom he had had experience—did not study the matter from the scientific point of view It had been proved that if matters were suitably arranged in the workshop there could be a higher output and efficiency consistently with shorter hours and no "drive" at all. The lessons of industrial efficiency were very little studied in the photographic profession. The speaker also complained of an unwillingness on the part of the employer to give the assistant prints which were his own work and which he could use as specimens.

Another assistant (a lady) said that the previous speaker's remarks only proved the necessity for discussing these things in common.

Another lady assistant said that the Association had been in existence for 21 years, and this was the first time that assistants were allowed to gather together. They were such utter strangers and so shy that it was scarcely possible to expect any full expression of opinion.

Mr. Hana said that the gentleman who had spoken had put his finger on a sore spot. But he thought that the rights and wrongs of the matter became more evident as the years went on. Twenty-one years ago before the Association was formed this complaint might have been made much more forcibly than to-day. Employers were more human to-day than they were then. The majority of them were beginning to recognise the true aspects of this question. If the Association should remain silent and offer no inducements to assistants, that, to his mind, would be a dereliction of duty. Lack of confidence was a very difficult matter to tackle, but he believed that it would gradually disappear. Surely there was no other work where people earned a living in which the spirit of comradeship was more necessary than in photography. Whose fault was the lack of confidence? Was it entirely the fault of one side, and not at all of the other? Might it not be partly the fault of both sides? A lady had said that they were strangers. If they had been strangers must they always be?

The President said that the feeling of the meeting appeared to be that the Council should formulate some scheme and ask the assistants to discuss it. He asked those who felt that the time had come to explore the possibilities of closer union to hold up the hand. (Many hands were held up, and there were no dissentients.) The President went on to give a homely little talk on the value of hard work to make up for the absence of genius, repeating a remark of his father, after he (the son) had visited a phrenologist and had been told of certain temperamental defects. "Well, if you have to fight against that, it only means that you will have to do more than the average person." He added that in his own establishment he was blessed with a lot of fine assistants, who studied him in every way. Therefore what could he do but study them? (Applause.)

Exhibition Pictures.

Mr. Marcus Adams then gave a little talk on "Exhibition Pictures." It was one of his greatest pleasures, he said, to face that audience, because they were fellow-workers. On several occasions he had had the pleasure of addressing fellow master-men, but that did not equal the pleasure of addressing assistants. Here was the genius of the future. He remembered well thirty years ago printing the first proofs and cleaning the floor and windows and doing odd jobs in his father's place. He had done everything that was dirty in photography, and everything that was clean, and he was thankful to-day for that education. To-day they often heard of professional photographers who bubbled up and produced most wonderful results. That was illustrated in the Air Force during the war. But he understood even there that the man who had the foundational training was the man who did the best work all the time. He recalled some kindly advice given to him by the late Snowden Ward, who caught hold of his arm on one occasion and said, "Now, Mr. Adams, I am going to give you a drubbing." He did give him a drubbing, and he (the speaker) left him with a determination that he would do better, and that his pictures should be accepted instead of being refused at the exhibitions. The reason why he took up exhibition work was in order to do something he was not paid for doing—something in which he had liberty to please himself. During that training he found that it was too much for him as a master man to expect to do it all himself. Therefore he had to undertake the training of the people round about him in order to assist him to accomplish what he wanted. Eventually, he was delighted to say, the people who happened to work round about him realised what he wanted, and in full sympathy assisted him to get what was to be seen on those walls. He had little to do with the printing of those pictures, but those who assisted him felt with him all the time they were working on them. He was simply trying to persuade both masters and assistants to work in sympathy, and not one against the other. His principle was that everyone who came in contact with him had a soul, and was every bit as good as he was himself, only—fortunately or unfortunately, probably fortunately for themselves—they were not masters.

He had carefully studied every picture in the galleries, and he believed they were better for the assistant's help in the production of them. Two or three years ago an exhibition of this kind would have been impossible, but it had grown from the exhibition which was held three years ago, and he could assure them that before many years the Association would take Burlington House with its many galleries If the assistants would put their backs into things, photography could be raised to such a pitch that many painters would have to tremble in their shoes as to where the next crust of bread was coming from' What could they do to assist their "bosses"? When they produced better work the clientèle would be better satisfied, the firm would be able to charge more money, and the assistants would find themselves compensated with higher wages, and if they were not, they should write to the Secretary of the P.P.A. about it. If there was a master so mean that he could not appreciate the brains of those who worked for him, then he was not fit to be a master. But that was not the kind of firm that was going to elevate photography. Here the speaker quoted Pirie Macdonald's illustration from the building of New York cathedral which was given in his lecture the previous evening and reported there. That was the spirit, he said, for every assistant to emulate. They had to produce a picture which should be worthy not only of the firm but of the person it represented. The crux of the whole situation was sympathy, unity, the work of the team. A motto he had preached for years was that if every assistant made it easier for the next person who followed on in the work, the work would go out with less friction and more happiness, and if the work was not got through happily there would be no exhibition pictures.

SHORT DISCUSSIONS.

On Wednesday afternoon a number of brief discussions took place, and the interest was well maintained throughout. Mr. Alexander Corbett took the Chair.

Should Brother Photographers be at Daggers Drawn?

Mr. Herbert Lambert opened a discussion on this question. In theory everyone would agree that brother photographers should not be at enmity, but in practice, although the drawn dagger might not often be seen, there was a tendency for the hand to be on the hilt, or at least for a little unnecessary coldness or suspicion to be in evidence. This applied more to provincial towns than to London. The attitude of "daggers drawn" was singularly difficult to maintain. He would not say that he had never tried to assume

it, but certainly he had never succeeded in keeping it up for very long. The humour of the situation would not allow of it. Human beings had not the semblance of lions, who might perhaps pass off such a situation with dignity. They were evidently meant to be comrades. It was not to the advantage, again, either of the individual photographer or of the profession as a whole that there should be any coldness or the exclusive individualism sometimes to be seen amongst those practising the same profession. What would happen in the medical profession if such an attitude were maintained there. The great thing to be considered was the improvement of the profession as a whole. A man might say that his rival had to be treated carefully, because the more the rival did the less there was for himself to do. There could be no more lying half-truth than that. The profession of photography, in this country especially, was not half nor a quarter developed.

In talking with some of the delegates from overseas he had learned that in America the custom of having a photograph taken was much more common than it was here in England, where thousands of people went through life without ever facing the camera at all. And the reason for this apathy on the part of the public was that a great deal of the work which was done was not really interesting. There was a formality about it, and a lack of life. If they could put more vitality into their work, more sympathy with the subject, and less suggestion of routine treatment, the general interest in portraiture would be very much increased, and a larger number of people would go in for photographs. Mr. Frank Brown had questioned on the previous day whether the kind of work sent to exhibitions was suitable for sending to clients. Most certainly it was. The selection committees or judges looked at the matter from a very similar standpoint to that of the public. In looking round the exhibition he could see scarcely a single picture which would not be an attractive thing for the sitter to possess.

If the general level of the work was raised there would be more work for photographers as a whole. Therefore, there was no need to keep secret any little process. The man who went about feeling that he must keep his processes to himself was likely to end up by being the only one who thought his results wonderful at all. He related an amusing story of how he had visited a photographer in a little town who, after being suspicious of him at first, afterwards said with a great air of mystery that he had got a new thing which was just wonderful. When the secret came at last to be revealed it proved to be the Eastman portrait film! Photography, after all, was such an interesting job that he did not see how any man who made a lifework of it could keep it to himself. The work was full of absorbing interest, though, of course, it might appear less interesting to the man outside, like the piano-tuner in "Punch" who turned round to an artist and said, "It must be a terribly monotonous job, painting pictures." The greater the amount of co-operation between brother photographers the better.

Mr. George Hana heartily agreed with Mr. Lambert. In the old wet-plate days photographers were rather in the habit of working individually and in secret, but now they met in the open and criticised and emulated one another. The broader outlook was evident on every hand.

Mr. Walter Stoneman took up Mr. Lambert's remark that it was the big men who were only too willing to be open and frank, and to encourage the others to talk with them. But surely that was because the big men were in such a position that they could afford it. Such men were six feet above contradiction. The man who was struggling—who found photography not only an art he enjoyed, but a method by which he earned his daily bread—did not find it so easy to talk over a matter with a competitor. There was only a certain amount of work to be done in a certain town, and it had to be shared by three of four photographers. How were these three or four to talk matters over?

Mr. Lambert said that it was a fallacy that there was only a certain amount of work to be done. People could spend their money on photographs or on something else, and if they were attracted to spend the money on photographs they would do so. The general level of American photography was more adventurous and more vital than here. If the work was made more interesting there would be more people running after it.

Mr. F. Read said that for many years there had been an undercurrent of hostility in some towns, but surely the strength of the Association ought to minimise that feeling. In Lancashire, the visit of the worthy President and Secretary this year, and previously of Mr. Lang Sims had done a great deal of good, and if only more members of the Council would meet the photographers in the various provincial towns it would act as a great unifying influence. In his trips to Canada he had been struck by the feeling of brotherhood in the eastern part of the Dominion among men following one particular calling, i.e., commercial travellers.

Mr. G. A. Futcher mentioned a case in which a photographer was making some experiments with shop-window lighting, which had to be done by artificial light, and was accosted by a rival photographer, who, meeting him afterwards in a dealer's shop, asked him about his stop and exposure. He told him the technical data, but he wondered what would be the proper course to take under such circumstances.

Mr. Lambert said that, of course, a rival might take advantage of such information, but, in general, he though the rivalry could be kept on a sporting level, which was perfectly compatible with friendship.

Mr. N. S. Kay said that he did not mind rivalry, but when a rival obtained knowledge which it had taken the other years of experience to accumulate, and immediately went and did the same thing and cut the price, it was not fair.

Mr. Drinkwater Butt said that there were two sorts of competition. The man who competed fairly was quite a good friend, since he stimulated one to do better work, but the man who competed unfairly must be treated with contempt.

Mr. Lambert agreed that if in this "sport" there was cheating it must be treated as cheating would be treated in ordinary games. But in fair sport one could enjoy one's opponent's fine strokes.

Photographic Parasites.

Mr. Frank Brown, in opening a discussion on this subject, said that "parasites" was an unpleasant term, but the thing itself was unpleasant. He was not alluding to small competitors who opened a little hut in a back garden and were something of a thorn in the side of the well-established business; nor was it the travelling photographer who made a pitiful yarn, and—especially when, as had happened three times in his experience, the person was a woman—intrigued himself or herself into one's sympathies. There was a class of individual who settled in a certain street, called himself by the same name as a reputable photographer of the neighbourhood, and went round the other side of the town soliciting orders for enlargements and collecting half-crowns on account, representing himself as from "Mr. Brown, of London Road." The people, knowing the good reputation of "Mr. Brown, of London Road," parted with their half-crowns and their pictures, presently to be disillusioned. More than once he had been tackled because his "representative"—of whom he had no knowledge whatever—had acted in this manner. These people commonly rented a room in the same neighbourhood as a reputable firm, and traded upon the firm's name. It caused much annoyance and some injury to one's local reputation. What remedy could anyone suggest?

In reply to a member, who mentioned a notorious case of the kind, Mr. Brown added that the Council had had complaints before it on several occasions, but the difficulty was that people who had been victimised had not the courage to come forward. If the Council could be supplied with full facts and particulars, proper advice would be taken.

Mr. J. M. Chew described a mushroom business in which three men had been victimised to the extent of each paying £150 for what proved to be quite a worthless concern, in which people had been defrauded over enlargements. The same speaker stated that he was commissioned to photograph the King's guard during his Majesty's visit to Aldershot, and while preparing to take the photograph he found another photographer present. Before the preparations had finished the guard dispersed, and on approaching the commanding officer he found that that officer had been under the impression that the other photographer was the authorised individual. However, the guard was reassembled and the proper photograph taken, but next morning the man who had "chipped in" submitted proofs before he could do so, and endeavoured to undercut him.

Mr. W. Coles said that the remedy was for local photographers to associate a little, sufficiently at all events to educate and warn the public in the matter.

Mr. Marcus Adams thought it would be a good subject for the daily Press to take up, inasmuch as it could be dealt with much more effectively from outside the profession than from inside.

Trade Enlargements.

Mr. F. G. Wakefield brought forward a grievance against firms describing themselves as trade enlargers who were "taking the bread out of one's mouth" by broadcasting trade price lists to business firms all over the country, with the result that the publicity departments of those firms knew exactly what these enlargements cost. He himself did a great deal of commercial work, particularly in photographing motor cars, but of late years he had done very few enlargements for the firms in question, and he found that they were being done by trade houses much more cheaply than he could do them. When he put forward a claim for a guinea, he was answered that the work could be done by one of these firms for 8s. 9d. If he refused to lend the negatives, his clients were likely to reply by closing the account. The ethics of the matter seemed plain enough. He had done his difficult work by getting the negative, and surely he was entitled to his profit on the enlargements. He would advise others not to lend their negatives if they could help it. The negatives should be regarded as the property of the photographer in the absence of an express stipulation to the contrary.

Mr. Drinkwater Butt pointed out that certain of these firms were working for the amateur at exactly the same price as for the professional.

Mr. A. W. Wakeling said that in every case he had an understanding as to whether the negative was to be his property; if the firm desired the negative, he made a special charge.

Mr. C. P. Crowther expressed admiration for the firmness with which Mr. Wakefield had stood to his guns.

Mr. W. Coles said that it was quite clear that they could not expect any sort of protection unless it was of a kind which could be legally claimed. The charge for any professional skill should be made in the execution of the original order. Everything that was complained of in these cases was quite open and above board. The advertisements were broadcast. It was rather absurd for the photographer to think that because he made a good negative he ought to get a fancy price for the enlargements. If people wanted the negative they must be charged accordingly. There was not much personality going into a technical enlargement.

Mr. Wakefield pointed out that clients approached one months afterwards with regard to the enlargements, when the charge for the negative could not be altered. It was a point of complaint that the firms of trade enlargers made the same charge to those in the profession as they did when working for the big firms—like Selfridge's, for instance—direct. He hoped that his remarks would draw attention to the grievance.

VISIT TO NATIONAL GALLERY AND NATIONAL PORTRAIT GALLERY.

On Tuesday morning a large number of members of the Congress met at the National Gallery, where special lectures were delivered by Mr. R. Gleddowe, Assistant Director, and Mr. Hubert Wellington, Official Lecturer, on "The Composition and Lighting of Pictures." One party started with Italian portraiture and worked round to Northern (Flemish) portraiture; the other began with the Northern work and worked round to the Italian.

Mr. Gleddowe began with some remarks on the pictures of Jan Van Eyck. He said that these pictures illustrated the fact that the absolute essential of portraiture was truth, and that quite subsidiary to truth were selection, design, and arrangement of lighting. The portraitist was producing a document which people would consult, not merely a work of art which they might enjoy. No painter had ever shown more zeal for truth than Jan Van Eyck. This Flemish painter employed two methods of portraiture which were exemplified in portraits in the gallery almost side by side. By one method he concentrated the whole attention on the features, and by the other he gave to surrounding objects and the background an equal importance. Photography, of course, was quite capable of making the surroundings of the same importance as the face, and perhaps more might be made of portraits which betrayed by means of typical objects used by the subjects the nature of their calling or their favourite pursuit. If, however, these objects were given equal definition with the portrait, as Van Eyck gave them in certain examples, it would not find favour. People would ask what was the use of giving a telephone a value and emphasis equal to that which was given to the face. Van Eyck, however, did this, and, after all, in Nature everything, whether features or inanimate objects, might be equally lighted up. He wished that someone would try to recover the value of the setting of the photograph, instead of leaving it as at present out of focus and carelessly arranged. He passed on to the work of Bouts, a contemporary of Van Eyck, to show how he got that quality into his paintings which was now called "atmosphere"—a quality which seemed to set the objects in a kind of rarefied air suitable to the subject itself. He thought that these early Flemings would gladly have employed photography had it been available; they would have used it as the basis for their painting. They would have produced a light print to give them the exact contours and forms on which their painting could be based.

Coming to the Rembrandt portraits, he remarked upon the presentment of character shown in the "Portrait of an Old Lady." Rembrandt was interested in the surface quality of his painting, but also in the character of his sitters. His treatment of the hands was always notable. Hands were quite frequently introduced in the portraits at the Royal Academy, but in many of such portraits they might be anybody's hands. If hands were worth putting in they were worth properly studying. The portrait of "The Borgomaster" by Rembrandt was a new thing in northern portraiture in that it suggested, not the permanent expression of the sitter's character, but a fleeting expression. Photography, of course, had an advantage over painting in this respect. Some of the works of Velasquez were noted in passing, and then Holbein, whose "Christina of Denmark" was strictly in the Van Eyck tradition. In this work Holbein had reduced the lighting interest to the absolute minimum. The light was direct upon the face, which meant that there was no modelling in the head at all except the slight relief of the nose. To give the subject the amount of character he did with that minimum help of lighting was an astonishing technical achievement.

Next he came to Gainsborough, reminding his hearers that Gainsborough painted portraits of English gentility, not for the purposes of real portraiture, but to furnish pleasing and decorative pieces for the interiors of rich houses. The portraits of the Baillie family were instances of shimmering surface and general charm, without the smallest psychological interest. Gainsborough, however, was quite capable of portraying character if he wanted it, and he instanced his portrait of Blackstone, and of his own daughters—the latter showing figures in quite violent motion. Some of Reynolds's work was pointed out, especially the heroic figure of Lord Heathfield, which was Reynolds at his best. He contrasted Reynolds with Hogarth, the former a man who believed in the aristocracy, and gave a heroic stature to certain figures, the latter a satirist, who believed that one man was as good as another. The picture of Hogarth's servants was full of first-rate character. Van Dyck's equestrian portrait of Charles I., Raeburn's works, giving singular delight to the eye for the quality of their paint, Sargent's "Lord Ribblesdale," and Millais's "Gladstone"—the last named remarkable for the eyes and mouth—were also looked at, and the tour finished in the Italian room, where the lecturer pointed out some of the glories of Titian, particularly his portrait of Ariosto, which for some reason had managed to arrest one generation after another.

The party then adjourned to the National Portrait Gallery, where the President (Mr. Swan Watson) pointed out various portraits in illustration and amplification of the remarks in his Presidential Address the previous evening. Among the points he mentioned were the desirability of getting the low point of view—i.e., keeping the camera low—in the case of people with small chins; the value of a shadow on the hand particularly if the hand was dropped over a chair, when, in the absence of such shadow, it was likely to suggest paralysis or rheumatism; the rarity of the smile in paintings of children by great artists, and here he found even in photography that if there was a repeat order for child portraits it was the serious and not the smiling portrait which was favoured; how Romney managed the delicate art of giving a faithful likeness and flattering at the same time; the fact that it was irregularity of feature which gave character; how in the case of ladies who let their hair fall over one side of their forehead and not over the other it was well to have towards the light the side over which the hair hung; and the truth of the old rule that a portrait should have either one strong light or three lights, one principal and two subsidiary. This last was illustrated by reference to Sargent's "Henry James," where there were but two lights, one on the

head, and the other on the hand, and where a third light seemed to be wanted. With regard to the many portraits in the Gallery into which some instruments or other objects to suggest occupation were introduced, the President's experience was that the modern man did not want to be associated with any accompaniments relating to his profession, and some even objected to a book because they thought it might look as though they pretended to learning.

These were only a few of the interesting points in a very educative tour, after which the members adjourned to Gatti's Restaurant and lunched together.

VISIT TO A HALF-TONE AND COLOUR REPRODUCTION DEPARTMENT.

On Wednesday morning members of the Congress visited the studios of Madame Yevonde, Messrs. Arthur Banfield, Angus Basil, Alexander Corbett, Reginald Haines, Layfayette, Ltd., the Hana Studios, Ltd., and J. Russell & Sons, Ltd. About fifty members, under the leadership of Mr. Lang Sims, accepted the invitation of General W. F. Mildren, C.B., to visit the half-tone and colour departments of the printing works of the Amalgamated Press, in Southwark. Here, in the course of two hours, the complicated processes necessary in the production of illustrated periodicals were explained and demonstrated. The guide on this tour was the head of the departments, Mr. R. Vincent. After the work in the old premises in Lavington Street had been inspected, the company was taken over to the large new building on the other side of Southwark Street, which the Amalgamated Press is to occupy in the course of a few weeks. This is a building whose exterior gives the impression of a smaller Crystal Palace, for the amount of glass used in the walling is remarkable. On the top storey of this new building there are to be five immense cameras, each consisting of a single dark-room, and fitted with 60-inch lenses.

On the roof of the building, from which a wonderful and unaccustomed view of the City of London is to be obtained, Mr. Vincent initiated those present into the secrets of pictorial reproduction on a colossal scale. He said that the department was responsible for the reproduction of the illustrations in some 85 papers. On an average, one complete block was turned out every three-quarters of a minute all through the day, and one complete weekly paper (counting monthly magazines as four weekly papers) was turned out, so far as his department was concerned, every three-quarters of an hour. It was necessary to be one, two, or three weeks ahead of publication, according to whether the periodical was of a topical or a non-topical character. The circulation of the eighty-five papers was some 11 million copies. Mr. Vincent went on to describe—what was already familiar to some of the audience—how line illustrations are photographed without a screen, while for the half-tone a screen is employed, the purpose of which is to break up the continuous tone of the negative so that the printing can be done down on to the metal in an acid-resisting substance. The variously ruled screens were exhibited, ranging from one of 64 lines to the inch for coarse newspaper reproduction, to one of 150 lines to the inch, or even finer. He stated that only three firms were making such screens—namely, Levy of Philadelphia, Brown of Leicester, and a German house. Two 20 x 30 screens used in the department cost £105 each. In the case of three-colour work, it was necessary to use a special angle so as to form a star pattern of dot, and if the lines were at any other angle the result would be a failure. The process plate was used for colour work, and it was simply a question of photographing through the three filters. The conventional filters were red, green, and blue, but there was no recognised standard for them, and every process man would declare that his alone was correct. The yellow, blue, and red printing negatives were printed down on to the copper plate. For very fine art work a grey block was also used, taken through a K 1 or K 2 filter, so as to give the general tonal value of the coloured original, but this was only for the reproduction of Academy pictures or similar work, and for ordinary work, such as magazine covers, the three colours sufficed. He pointed out the absolute necessity for a perfect reproduction of the negative as an acid-resisting print. Up to this point the process was purely and simply photographic, but after this, it left the photographic side of the business entirely, and became a different trade. The blocks went over to the etching department, where the etcher by one method or another would get away the unwanted metal. He emphasised the specialised skill necessary in the different operations, and added that lads were apprenticed for the different parts of the work, usually for five years. One interesting remark was that the late Lord Northcliffe for some time entertained the idea, of which it was very difficult to disabuse his mind, that the "Daily Mirror" could be produced in colour. It was necessary to marshal the technical objections in a very exhaustive treatise before he was convinced of the impossibility.

To the casual observer with a philosophic mind the wonder was to see so many men engaged with intense application at rows of desks improving colour work stage by stage, as careful of every little detail as though there depended on it whether a king was made to frown or to smile, and in the result nothing but a further instalment of the adventures of the "Bruin Boys" or "Tiger Tim"!

Before leaving the building, the visitors, on the proposition of Mr. Lang Sims, passed a hearty vote of thanks to the Amalgamated Press and the departmental director for a morning of instruction and entertainment. Mr. Vincent briefly expressed his pleasure in having acted as guide.

War Grave Photographs.—Relatives of British soldiers buried in French war cemeteries have been informed by the Imperial War Graves Commission, 82, Baker Street, W.1, that photographs of graves are no longer being taken by the War Office, and that the Graves Commission does not take such photographs itself.

The British Industries' Fair.—The Fair for 1923 will again be held at the White City from February 19 to March 2. Forms of application for space have just been sent out, and should be filled up and sent in by October 7 at latest. The Board of Trade announce that they have been able to reduce the charge for space by 6d. per square foot, and accordingly it will now be 3s. The cost of the stands erected by the Department for exhibitors will also show a very considerable reduction, so that the total cost of showing at the Fair will be appreciably lower than in recent years. All particulars may be had from the Secretary, British Industries' Fair, 35, Old Queen Street, S.W.1.

Polytechnic School of Photography.—The 1922-23 session of the school of photography at the Regent Street Polytechnic, opens on Monday next, September 25. The school, under the direction of Mr. A. J. Lyddon, provides day and evening courses of training in studio portraiture by day and artificial light, negative making and printing, retouching and colouring, enlarging, commercial photography, in addition to half-tone block making. The classes are conducted by Mr. Edgar Clifton, Mr. L. J. Hibbert, Mr. H. G. Harrison, Mr. H. C. Standish, Miss N. Hill, and Mr. Lyddon, the last-named of whom will be glad to advise intending students on the courses which they may take up. As we know, students receive a thorough and practical training, and one which is of great advantage to them in earning their living by photography.

Einstein's Theory Tested by Photography.—Photographic proofs of Einstein's theory that space is curved, and starlight bent out of the straight line, obtained at the time of the eclipse of the sun in May, 1919, were due entirely to English astronomers, says the "Daily Chronicle." These made their preparations hurriedly on the sudden termination of the war providing the opportunity to make the necessary journeys to Brazil and West Africa. Because of this, the photographs were not generally accepted as conclusive. On Thursday of this week (September 21) another opportunity was afforded by a total eclipse of the sun visible from the Indian Ocean and Australia, and many parties of astronomers—English, Australian, American, Dutch, and German—made elaborate preparations to photograph the stars near the sun at the moment it was totally eclipsed by the moon. It is to be hoped that sufficient photographs have been obtained to settle once for all the question of the deflection of light, which is a necessary corollary of Einstein's relativity theory of gravitation.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, SEPTEMBER 25.

Southampton C.C. Judging the President's Competition.
South Glasgow C.C. Outing to Callander
Wallasey Amateur Phot. Soc. Photography as a Hobby. A. H. Farrer.

TUESDAY, SEPTEMBER 26.

Bournemouth C.C. Competition. "Pictures without Words."
Hackney Phot. Soc. English Ecclesiastical Architecture. J. Cox.
Manchester Amateur Phot. Soc. Lecturettes (a) "The Treatment of the Sky in Lantern Slides"; (b) "Dark Room Devices." W. W. F. Pullen, H.M.I.

WEDNESDAY, SEPTEMBER 27.

Rochdale Amateur Phot. Soc. Exhibition of Members' Holiday Prints.

THURSDAY, SEPTEMBER 28.

Hammersmith Hampshire House Phot. Soc. "Durham." Robert Chalmers.

SATURDAY, SEPTEMBER 30.

Bradford Phot. Soc. Outing to Sunnydale.
City of London and Cripplegate Phot. Soc. Outing to Westminster.
Edinburgh Phot. Soc. Outing to Roslin and Polton.
Hackney Phot. Soc. Outing to Gerrard's Cross and Chalfont St. Peters.
Hammersmith Hampshire House Phot. Soc. Visit to the London Salon.
Wallasey Amateur Phot. Soc. Outing to Liverpool, Old Buildings and Docks.

CROYDON CAMERA CLUB.

Dr. D'Arcy Power, the editor of "Camera Craft," hailing from the other side of the herring pond, gave a most interesting evening on a method evolved by him for chemically toning bromide prints in two colours, and then employing them as a basis for the application of coloured pastels. Many, unfortunately, seldom seen faces turned up for the occasion, including distinguished visitors.

A number of prints illustrating the process were on the walls, some excellent indeed, others in general opinion (freely expressed after the lecturer had left) not quite so happy. Owing to circumstances beyond control no examples of portraiture were included, but all pointed to the fact that the method would be highly applicable to camera portraits, especially those in delicate key.

From the nature of the medium there is a tendency to block the shadows, with gain in effect in some cases, and undoubted loss in others. In the lighter tones the delicate bloom and atmosphere of pastel work is well preserved, and to some extent the photographic base disguised, though plainly evident to the trained eye. Essentially the process is a difficult one, and there is no muddling through, for in the preliminary treatment of the bromide print the desired effect has to be gauged in advance, by no means an easy task.

Briefly, a bromide enlargement is bleached locally, and then immersed in the sulphiding solution. Local gold toning follows, the black portions of the picture assuming a bluish tint, and the sepia parts warmer shades to bright red.

Although two colours only are produced, others are simulated in very puzzling fashion. This was strikingly evident in a two-toned print of an open forest glade in mellow evening light. Here the orange glow in the sky, and warm broken patches in the foreground, induced a complementary and appropriate green hue to the foliage. Only by covering the other parts could it be ascertained that the green was but a pleasing fiction of the brain.

To this two-toned photograph coloured pastels are applied in the usual way, by stump and flannel. A moderately rough (American) bromide paper is used containing the minimum of gelatine. The ordinary fixatives are unsuitable for locking the powder colours; steaming the print answers well.

So far, the cart has been placed in front of the horse, for Dr. D'Arcy Power started with many helpful references to line, tone, and colour in its psychological aspect, and he expressed a confident opinion that if photography is to realise itself fully, colour must come ultimately. No mere mechanical transference of Nature's colours to paper or glass, however, will suffice, and whatever method he evolved it must be one which will allow the intervention of the artist.

In Nature, by the juxtaposition of different colours mutual reinforcement occurs, and a mass of one colour will always excite a sensation of a complementary colour in regions adjacent. For this reason the shadows in foliage never appear green. Also a large area of predominant colour in Nature rivets the attention to the subordination of surrounding tints. Reproduce this ever so faithfully on, say, a small screen-plate and the main *motif* is lost, for no longer the predominant colour rivets the attention, owing to other colours, unnoticed in the original scene, becoming very apparent.

If one has to suggest colour contrast in monochrome, he said, in nearly every case a certain amount of falsification, or departure from real facts, is necessary, and usually the warmer colours are rendered the lighter. This applies not only to photographers, but equally to engravers. Frequently, he continued, the run of the tone values is detrimental to good composition, and in such cases it is often possible to compel the eye to follow a better colour line, with consequent improvement to the picture.

Remembering that artists not infrequently use a painted base of warm and cool hue to receive the pigments, the idea struck him that a two-toned bromide print would form a good base for the application of pastels, and so it proved. No artist, he said, will tolerate a black and white photograph coloured with transparent pigments, as the black tells through and degrades all colours. His system avoided this, and also preserved structure.

Mr. Salt opened the discussion by saying that if the lecturer had seen some really beautiful portraits in heavy vein, which were dependent upon the application of transparent pigments to a monochrome photograph, and recently shown in the Club, his opinion as to this procedure would undoubtedly be modified, if not reversed. No method of graphic expression equalled photography in its capacity to represent texture, and transparent colours, obviously, must retain this in greater degree than would be possible with pastel pigments of greater opacity.

Mr. G. E. Brown said he would express no opinions on matters of art, but felt compelled to express the pleasure he had experienced in listening to a most interesting address, in which the technics of the process had been admirably expounded. All present might not know that Dr. D'Arcy Power was one of the first to devise vertical enlargers, the forerunners of present-day very perfect appliances. Also, he had done much pioneer work with quartz lenses for portraiture.

Mr. Harpur (whose habit of looping the loop several times before landing on the subject, obviously astonished the lecturer) said unkind things about Bromoil, the relevancy being that the pastel pictures exhibited far better hand-introduced clouds. Mr. Hibbert pointed out that two-coloured pictures of sorts could be obtained by the local application of salt solution to self-toning papers. By bleaching a print in lead ferricyanide multi-coloured pictures were possible by locally toning with various reagents. Mr. Purkis followed with a few remarks on panchromatic plates, which some years ago would have been informative to many.

In answer to many questions on the quartz lens, Dr. D'Arcy Power passed round some specimen prints from negatives taken with the "Kalosat" quartz lens working, it was stated, at *f*/5. They were really superb, combining good definition with slight diffusion of beautiful quality. The "Kalosat" is a meniscus single-lens, and compared with a crown and flint achromatised counterpart, is, he said, about 2½ times faster, aperture for aperture, owing to the quartz allowing free passage to the highly actinic ultra-violet rays. Contrasted with other achromatic objectives of greater thickness, or possessing many components, the comparative speed of the quartz lens would be proportionally greater.

As the dispersion of quartz is only about one-tenth that of crown glass, it is not necessary to rack the lens backwards after focussing, as is customary with an ordinary uncorrected single lens. The quartz lens requires to be free from strim, which if present will seriously impair definition.

With much acclamation a most hearty vote of thanks was accorded the accomplished lecturer for an evening of unusual interest. With only brief headings to refer to, he spoke with great lucidity and rapidity. The last feature places it out of the power of a longhand reporter to do justice to the discourse. Speed, however, was essential, as much ground had to be covered in a limited time.

Correspondence.

THE BEGINNER IN PHOTOGRAPHIC SOCIETIES.

To the Editors.

Gentlemen,—Few society secretaries will agree with A. V. W., whose letter in to-day's "B.J." plainly indicates that he regards "the absolute beginner" as little more than a nuisance. His proposal to admit to membership only those applicants who have had a year's tuition at a "school of photography" is not only an extreme view, but a dangerous one at a time when most societies are making great endeavours to extend their membership, and it should be scotched at once.

The beginner should be regarded as a society's greatest asset, for, if properly nursed, the photographic baby will very rapidly grow, and almost every batch of beginners produces at least one worker whom the society, two or three years after, is quite proud to own.

Every association should be a "school of photography" in itself. If it cannot number among its own members those who are willing and qualified to instruct beginners, adequate help may be had nowadays from other societies and from trade demonstrators. But the deficiency arises, as likely as not, only among newly-formed societies, or those who in the past have adopted the wrong attitude towards the beginner, and who are consequently reaping what they have sown.

As a rule a society will find it advantageous to supplement its usual weekly fixtures with a separate syllabus of demonstrations for beginners, and if the tyro continues to "butt in" during advanced workers' discussions, he can be invited to repeat his question at the appropriate meeting, or at least defer it until the close of the meeting, when the speaker can deal with the beginner separately, and so avoid slowing down or side-tracking the main stream of the discussion.—Yours faithfully,

W. H. Gleave.

Liverpool Amateur Photographic Association,
11, Dale Street, Liverpool.
September 15.

To the Editors.

Gentlemen,—The Utopian ideas of your correspondent, A.V.W., would have gladdened the heart of Sir Thomas More—the originator of the imaginary island—had he been alive to-day, but excellent as they are in theory, they do not come out well in practice. Your correspondent's arguments, carried to a logical conclusion, would mean that an amateur photographer would have to attend a photographic class, and get a certificate or something of the sort before he would be permitted to join a photographic society.

Most amateurs—probably 95 per cent.—take up photography as a hobby or pastime, and not as a business. Camera work is to them what fretwork, coin, stamp and butterfly collecting are to others. One does not go to a L.C.C. evening school to learn, say, stamp-collecting, and there is no reason why a would-be photographer should go to classes for photography—when he practices the art simply as a hobby.

Photographic societies are not what they used to be, say, thirty years ago, and I wonder if your correspondent realises the fact that the beginning of dry rot in photographic societies commenced when L.C.C. classes began. Had there been no cheap photographic classes (provided at the expense of ratepayers), photographic societies would never have lost their hold. My experience—probably an unfortunate one—is that L.C.C. photographic classes sometimes breed a species of photographic prig, an individual who, filled to the brim with ready-made knowledge, as per school curriculum, occasionally endeavours to teach his grandmother the gentle art of egg-sucking, and who has no desire or even any encouragement, to go beneath the surface and find things out for himself. It was those who had to find things out for themselves, and not the modern spoon-fed "expert," who made photography the beautiful and wonderful art it is to-day.—Yours faithfully,

An Old Hand.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

C. C.—The Barkay reflector is made and sold by Messrs. W. J. Bartholomew & Co., 40, Gerrard Street, London, W.1, who would readily tell you the best pattern to use in your circumstances, and also the distance from background.

W. M.—As a rule, the masks used for clouds in aerograph work are made of stout blotting paper, torn as the fancy of the operator dictates. You will find a great deal of useful information on this matter in "Sketch Portraiture," which our publishers can send you for 1s. post free.

E. P.—The following are the three chief French trade journals:—(1) "La Revue Francaise de Photographie"; (2) "Le Photographie"; (3) "L'Informateur de la Photographie." No. 1 is an amateur paper, No. 2 for professional photographers, and No. 3 for photographic dealers. All are published by M. Paul Montel, 35, Boulevard St. Jacques, Paris.

A. C.—The best recommendation we can make is that you soak the negative in a solution of soda bissulphite, or, if you have not any of this, in a solution of potass. metabisulphite, in either case of about 5 per cent. strength. It may take a long time, but this is about the best solution for removal of the bichromate stain. It would seem as though the particular plates you are using are extra liable to be stained by bichromate.

G. M.—None of these processes of converting a negative exposure into a positive bromide print are very satisfactory, owing to the somewhat thick film of the emulsion. The more thinly coated papers, such as are supplied for use in the Photostat machines, are more suitable, and for them a process was worked out a year or two ago by the Eastman Research Laboratory, and was fully described in the "B. J." of February 9, 1917, p. 68.

N. S.—A gas light of any kind is useless for your purpose, whether alone or as a supplement to daylight. You could, of course, use flashlight with advantage technically, but we do not think it can be recommended for your special purpose of the portraiture of children. If you really want to do the job effectively, you had far better have electric current connected, and instal one or two half-watt lamps to a power of about 3,000 or 4,000. You don't say what plates you are using. Perhaps you could reduce your exposure somewhat by using a very rapid plate.

Contents.

SUMMARY.

In a leading article we refer to the important proposal brought before the recent Congress of the Professional Photographers' Association for the co-operative advertising of portrait photographs. The scheme is based on the sound view that the competition which photographers need to unite in meeting is that of the vendors of other articles which, to a greater or lesser degree, are luxuries. We believe that the P.P.A. is the body which should initiate a scheme of this kind in the interests of the portrait photographers, both within and without its membership. (P. 586.)

Mr. John Mills, of Northampton, writes in support of the scheme, and adds the suggestion that it needs to be supplemented by the provision for the public of a suitable receptacle in which to keep portrait prints. (P. 598.)

At the P.P.A. Congress, Mr. Charles Aylett, of Toronto, gave a demonstration of less usual methods of lighting, consisting chiefly of various forms of back lighting. He made a strong point of the great commercial value of a soft-focus lens. (P. 590.)

The proceedings of the Congress ended with the annual dinner, and with the enthusiastic installation of Mr. Alexander Corbett as president for the current year. (P. 593.)

We publish this week, on page 592, a key to the members of the Congress group, reproduced in last week's issue.

In reviewing the landscapes in the pictorial section of the present R.P.S. Exhibition, Mr. F. C. Tilney concludes a most comprehensive and detailed survey of the pictorial harvest at the three exhibitions in London. (P. 587.)

The technical sections of the Royal Exhibition at Russell Square are stronger than in recent years. Lantern transparencies are a new feature. (P. 588.)

In the lantern slide section, Mr. Dudley Johnston shows a large number of lantern slides illustrating the methods which he uses for obtaining a wide range of tones by means of thiocarbamide developer. His working formulæ will be found on page 596.

In the colour section of the R.P.S. Exhibition, the Autochrome and other transparencies mark an average level of technique. Among the colour prints by far the most notable exhibit is that by Mr. Samuel Manners of prints by the Raydex method, showing a great advance in technical excellence. (P. 590.)

Mr. D. Charles sends us some excellent prints supporting his strong recommendation of flashlight for the portraiture of children. (P. 599.)

A correspondent gives the developing formula containing ferrocyanide, which at one time appears to have been largely in use in America. (P. 599.)

In the adjustment of intensity of illumination in a printing box appropriately to the character of the negative or of the printing paper, the most satisfactory means is a "damper" of the light consisting of one or more sheets of ordinary thin paper. (P. 596.)

In obtaining the best services from assistants more regard may often be paid to the avoidance of useless labour, a repitition of which lowers the efficiency of assistants, both physically and mentally. (P. 585.)

EX CATHEDRA.

The 1923 Almanac

With the smoothness and momentum acquired by many years of practice the "British Journal Almanac" (for 1923) is pursuing its accustomed path towards publication on or about December 1 next. Like time and tide the "Almanac" is one of those institutions which in the order of things laid down by the autocrats of our publishing department cannot wait in the progress of its production, not from any inherent perversity, but simply because contracts with printers and binders have to be exactly met in the case of a volume with an edition of 30,000 copies, each consisting of many hundred pages. It is, therefore, necessary specially to draw the attention of intending advertisers to the fact that the last day for the receipt of advertisements is

THURSDAY, OCTOBER 12.

At the same time our publishers ask for the assistance of those few advertisers from whom they have not heard, in the shape of the earliest possible intimation of their requirements in the forthcoming book. But immediately after 6 p.m. on October 12 the volume will be finally made up for the press, and, therefore, it is a remote chance that any stray orders which come in after that time can be accepted for the volume which will be in circulation next year.

* *

Time and Motion Study.

An assistant who spoke at the P.P.A. meeting called attention to the pamphlets on this subject to be obtained at small cost at the shop for Government publications in Kingsway. An example of the need for study of such matters in photographic establishments was that of an assistant called upon to make regular batches of copies with the ordinary studio camera. From the place allotted for pinning up the originals to the plate-changing bench in the dark-room was over twelve yards. The number of yards walked in pinning and centering the original and in switching on and off the lamps for each one was found to average another five. The very heavy dark-slide held only one plate, so that the total distance walked for each copy was about forty yards. Therefore, for every lot of forty or fifty copies made the assistant walked over a mile merely in getting the plates exposed. This is one example of many that could be cited to demonstrate the amount of time (and therefore money) spent in unnecessary labour. Still less is it realised that a secondary but serious result of such wasted effort is to induce a certain amount of mental and physical fatigue, and when carried to excess a feeling of resentment also, that has a very great effect of slackening speed and concentration upon the worker, especially towards the end of the day. The actual cost, therefore, of such unnecessary work is con-

siderably greater than can be calculated merely by the sum of the wages per hour taken up by that particular occupation.

* * *

Control of Printing Light. It is a mistake to believe that, in exposing bromide or gaslight papers, a short exposure to a strong light will give as good a result as a longer exposure to a weak one, even allowing that the actual illuminating value of one may be exactly equivalent to that of the other. Experience proves that with very thin negatives much more vigorous prints may be obtained by using a well-subdued light. This is easily obtained by increasing the distance from the light when using a printing frame, but most printing boxes, even when the light is movable, only allow of a variation of a few inches, when very often a good many feet would be necessary. Again, reducing the number of lamps is generally inadequate, a single 16 c.p. lamp being often too intense at close quarters. Probably the most satisfactory "damper" is made of one or more sheets of ordinary thin typewriting paper placed a few inches below the negative. When these are in position a thin negative actually appears to be stronger, and the sensitive film is evidently impressed in the same way. When enlarging, a similar result may be secured by stopping down the lens, a ground glass screen being placed between the light and the condenser.

CO-OPERATIVE ADVERTISING OF PORTRAIT PHOTOGRAPHS.

THE subject which more than any other aroused interest at the recent Congress of the Professional Photographers' Association was undoubtedly the scheme of national advertising for the stimulation of the demand on the part of the public for portrait photographs. Both the principles and the details of such a scheme were expounded in the very able and explicit address delivered by Captain F. H. Wright, of the London Press Exchange, who was followed on a later occasion by Mr. Hopton Hadley. The recommendations of these two advertising authorities tallied in almost all respects, and, therefore, it was not surprising to find that the scheme, as outlined, met with unanimous approval by those who listened to the addresses, and that, after some discussion, the matter was referred to the council for their report in due course to the members.

It is hardly necessary for us to recapitulate the advantages which a scheme of this kind offers for the expansion of the business of photographic portraiture. The examples of the benefit derived in other branches of commerce, details of which were given by both the speakers we have mentioned, are sufficient to show that under skilled administration a concerted scheme of this kind achieves results which could never be accomplished by indiscriminate individual effort, and does so at a fraction of the cost. Moreover, we referred to this very question as recently as in our issue of February 10 last, when we set forth pretty much the same facts which in greater abundance have been brought before the notice of the Congress. Still, it is desirable to underline one basic fact upon which a scheme of this kind rests; and particularly so, since precisely a contrary view appears to be in the minds of many photographers. It seems to be thought that for some reason or other a limit has been finally reached of the amount of money which the public as a whole will spend on photographic portraiture, and that, therefore, any advertising is simply a process of robbing Peter to pay Paul. But we are convinced that further consideration by those who may somewhat indefinitely hold this view will show that it is a fallacy. For example, one has only to look at the enormous growth within the last few years of studios offering photographs at relatively very low prices in order to see the great extent to which certain fresh classes of the community have spent money on photographs which previously they spent on something else. There you come to the crux of the question, namely, that the competitors of an individual photographer are all the other traders who offer goods of a kind which are not necessities of life. They are the competitors at least as much as the other photographers in his district, to whom chiefly he has directed his attention in meeting competition. Hence follows the altogether sound doctrine that photographers as a whole should unite in putting into effect a common policy directed to meet this competition from the vendors of other goods which may be classed as luxuries or semi-luxuries. Propaganda of that kind is bound immensely to benefit photographers as a whole.

When we turn from the general question to practical ways and means of carrying out such a scheme, the subject offers several debatable points. As was suggested by both the speakers at the Congress, the Professional Photographers' Association, as the representative body in the Kingdom, undoubtedly should be the one to bring a scheme of this kind into being. On the other hand, the P.P.A. has at present a membership of about 1,100, which is approximately one-seventh of the total estimated number (8,000) of portrait photographers in the United Kingdom. It is, therefore, perfectly clear that in organising a scheme of national advertising the P.P.A. cannot leave the six-sevenths out of consideration. It must enlist their support, or at any rate the support of a considerable number of studios outside its own membership. If the P.P.A. takes up this question on the broad basis of benefit to all photographers throughout the Kingdom, we think there is no doubt it can obtain the degree of co-operation which is necessary. Moreover, it is a reasonable anticipation that manufacturers of photographic goods would take a share as contributors to a scheme which necessarily would benefit them appreciably, if in lesser proportion than portrait photographers themselves. But the scheme must be organised in this single aim, and the Association be prepared to regard the increase of its membership as a benefit incidental to its larger national work. We think it will not do to mix these two aims in approximately equal proportions, and we mention this matter because already there are signs that the scheme is regarded in this two-fold aspect.

It may, indeed, be suggested that for the purposes of a national advertising programme a body should be formed, financed by the contributions of studios within and without the membership of the P.P.A. and placed under the control of trustees, likewise chosen from those who are members and those who are not. Whatever plan may, however, be adopted for enlisting support on the widest basis, there can hardly be any doubt that the practical management of the scheme is one for the advertising expert, whose business it is to make the psychological appeal to the public and to employ the channels of Press advertising of which he has an intimate knowledge. We daresay that an advertising man would welcome the opportunity of bringing before the public articles, such as portrait photographs, which particularly lend themselves to so many different and attractive forms of appeal. The booklet issued to members of the Congress by the London Press Exchange served to show the forcible advertisements which could appropriately be used.

THE EXHIBITION OF THE ROYAL PHOTOGRAPHIC SOCIETY.

In continuing a notice of the Exhibition of the Royal Photographic Society, now open at 35, Russell Square, London, W.C., we publish a further review of the pictorial section by Mr. F. C. Tilney, in which he deals particularly with the landscape and architectural exhibits which at the Royal this year form a fairly large proportion of the whole collection.

The scientific and technical exhibits are this year more highly sub-divided than has hitherto been the case, and have been separately judged by a correspondingly larger number of committees. The natural history section, notice of which will appear in a later issue, is the largest and best which the Society has ever brought together. The section "Technical Applications of Photography" has perhaps a somewhat misleading title, since the chief exhibits in it are those illustrating the properties of emulsions, forms of silver bromide grains, and examples of other research work done with the purpose of advancing the manufacture or use of photographic materials. However, the finer arrangement of examples of technical photography is a step in the right direction, and no doubt will have the result of attracting a greater number of contributions in future years from those engaged in these branches of work.

LANDSCAPE IN THE PICTORIAL SECTION.

The example of the landscapists of note is having the effect of bringing forward the obscure worker with more definite self-expression, and it is imbuing others with a righteous determination to share the ground with the eminent ones. A pleasing feature of this Exhibition is the appearance of fine work by photographers who have not yet won the reputation they deserve. Thus we have the names of Ashbee, Reece, Pickwell, Unsworth, Beauchamp Hall, Gleave, and others bringing honour to themselves and to the Exhibition; whilst men like Bairstow, Felton, Keith Dannatt, Lomax, and L. Banfield stake their claims with the few whom we accept as gifted.

From Australia comes the work of A. Wilkinson—"Monarch of the Glen" (64) and "Overlooking the Plains of Adelaide" (69), the latter a noble Claude-like subject, quite straight, and treated with much feeling. But perhaps the heartiest congratulations are due to W. H. Ashbee for three excellent landscapes, "A Downland Farm" (5), "The Arun" (14), and "The Druids' Table" (90), which is the best. It is a fine, expansive view from a hill-top, where there is what looks like a cromlech in the form of a seat or table. Two men on a lonely shore that is bathed in misty light is the subject of C. J. Unsworth's "Gleaming Light and Evening Grey" (70). The sun reflections in the shallow ripples are very effective. W. L. G. Bennett's mountain path, with a capital sky, and called "A Gleam through the Clouds" (74), has romance and feeling; and another good mountain scene is "Newlands Pass" (37), by W. T. Graham. A happy composition and effect comes from Dr. C. Beauchamp Hall in "Softly Fall the Shades of Evening!" (80). Perhaps the light reflected in the stream from the sky is relatively over-bright, both for nature and pictorialism. In "The Common Task" (124) H. Pickwell has achieved with much truth the effect of a sultry sky over a distant town. On the near shore of a stretch of water are the washing places for laundresses, one of whom is seen at her task. This is a work of immense promise. W. H. Gleave also raises high hopes by his picturesque "Italian Lakeside" (130), which has a full variety of tone and excellent composition. The charm in G. C. Weston's "On the Moorland" (93) is traceable to a concentration of light in a grand subject. His "Surrey Lane" (123) is delightful, too, in its variety of tone. Less varied, but of considerable feeling, is J. Ainger Hall's "Hurley" (122). White houses, black roofs and dark mountains make up A. V. Insole's striking "Jenerilfe" (42). A desolate scene in a manufacturing town is made pictorially beautiful in Miss G. Openshaw's "Winter in the North" (107) by sunlight and its glints upon a little stream that runs by a shed and a tall shaft. Miss E. Chatterton also had an idea in her shadows of trees upon a field in "Morning Shadows" (115); and the highly figured reflections in water form the idea of H. G. Allen's "Reflections" (131); whilst in "The Month of March" (134), by J. J. Butler, the idea is evidently of melancholy. Stanley Watson's shipping scene, "Lowestoft" (139), is quite distinguished. All these works would have been exceptionally fine years ago; to-day, good as they are, they constitute the general level of this Exhibition.

Among the more familiar names we find A. K. Dannatt, with his Dutch figures in "Homewards" (35), whose shadows are inexplicable, but of which the feeling is indisputable; Herbert Felton, who gets the true touch in "Evening in the Pines" (34), and whose "Guildford" (38) is one of the ornaments of the show, in spite of its unmodulated sky. Harry Abbott, junr., with his good "Storm Clouds" (57), and "The Cumulus" (51), by Chas. F. Stuart, beautiful in effect but unnecessarily low in key. Then H. Y. Sümmons surpasses himself with a splendid arrangement of tones and masses in "Arch of Constantine" (153), and uncommon feeling in "Night's Approach" (76). Frank H. Read sends a fine panorama of "Rouen" (15). Lewis E. Banfield, a striking but rather mixed-up group of orientals, smoke, and a gleam on a wall in "Hasheesh" (77). From A. C. Banfield comes a first-rate composition, with a big clump of elms, called "A Sussex By-road" (81), and a real sense of light and open-air in "On the Edge of the South Downs" (89). Very fine skies are the great feature of two landscapes by J. B. Portway, senior, the latter being "The Track" (91), with its gleaming sea margin. H. W. Bennett gives us the over misty "Durham" (92). But one of the most startling pictures for truth of effect is the "Arrens" (73), with its wonderful sunlight in the street, by M. O. Dell; and that is run pretty close by H. van Wadenoyen's "Sunlight on Stone Wall" (82), an exercise of much quality. Snow in the woods and the shadows on the ground give us "Nature's Carpet" (85), designed by S. Bridgen with proper regard to the value of a broad space.

Four of F. Judge's exquisite little pictures will be welcomed, particularly the "Dover" (144), a shipping subject, and, best of all, "In Glean Lean" (143), which rises to the height that Mr. Judge reached when he first exhibited his oil transfers. It is a very delightful scene, wherein the placing of two sheep to carry the light spot in the scheme is masterly. Charles Job, likewise, does not fall below his own standard in "The Arun, near Bury" (147), a work of much feeling. I think the light on the river to the right might have been a thought less bright with advantage. And I would also suggest that in Alex. Keighley's very noble subject, "The Hillside Road" (60), a little more daylight on the road would correspond to our experiences of the condition he depicts—more, in fact, as the reproduction in the catalogue renders it. "Tranquility" (58), his other work, is a placid stream reflecting, very dimly, the white houses upon its banks. There is a capitally designed tree on the right, which completes the pictorial effect.

T. H. B. Scott is revelling in dark tones this year. His "Threatening Weather" (36) would surely be even finer than

it is for a little more light on the horizontal planes. In "A Pyrenees Team, Lourdes" (68), he uses grand material, with the same dark method, which certainly gives him richness and quality in the print, though it does so at some sacrifice of delight on the part of the nature-lover. "The Old Church, Lourdes" (135), has not the excuse of "threatening weather," for it was photographed on a halcyon day; yet we are able to see far into the depths of the shaded parts of the building, the sunlight on the ground before our eyes notwithstanding. But there is luminosity in the sky, because of its tender gradations.

Bertram Cox, in "The Face of the Down" (55), has favoured the unconventional. His foreground object here is the immense side of a chalk cliff that we see over the edge of its upper surface. So big is this feature that it almost, but not quite, makes up for what it loses in strength of tone as a foreground object such as he gives in the big clump of elms in "Arun Meadows" (121). This work is therefore the more effective pictorially, though it has not the charms of the distant parts of "The Face of the Down." Mr. Cox's big trees are always fine, they have such life and character, and are so round and solid in their light and shade. Those in "Sussex Elms" (133) are of that variety of which the stems are kept trimmed, and are therefore clothed with short shoots of verdure. "Evening on the Arun" (65) is a little complex perhaps, but is full of feeling.

Landscapes from Abroad.

Of course, the attractiveness of our shows are always helped by contributions from the Colonies and Dominions, besides those from the Continent. There are five gentlemen whose works, here, have been much admired, and yet in photography, as in the other media, landscape remains an English art. Dr. R. S. Lovejoy shows remarkable feeling in "Nature's Spires" (21), which are poplars before a broad and well-gradated sky; whilst there is scarcely anything else but feeling, and plenty of it, and of the true poetic sort, in August Knapp's perfectly simple "Dawn" (44) and "The Poetry of a Distant City" (47). These little poems come from West Australia. Dr. Lovejoy's come from Maine, U.S.A., whence also do the works of F. O. Libby, well-known in our galleries. One of the most successful he has ever sent, because the most truly naturalistic, is "The Lake Below the Hill" (24), one of the nocturne subjects he is so faithful to. Here the moon shines down into a misty hollow, where a gleaming lake is seen between the branches of a fir-tree in the foreground. J. P. Edwards, of California, sends also a remarkably poetic architectural subject called "A Sierran Temple" (48), with a wonderful sky; and in "Hague Street, New York" (128), a great arch, most impressively rendered. N. P. Moerdyke is from Los Angeles. His "On the Wharf" (20) gives an artistic culmination of light upon a man's shirt in a mass of material treated with skill and showing much quality. Then we have our old friend Leonard Misonne, whose three landscapes are a welcome addition to the show. They are rather a departure from his usual style, and therefore exhibit further resources and talent. The steaming plough-team in "Attelage Fumant" (27) shows more realism than usual, whilst "Jeunes Pêcheurs" (22) is firm and dark, and not a bit misty; with its two children, at middle distance, by the water-side "Aurore" (54) gives charming gradations of light among small trees.

Architectural Subjects.

The Royal always preserves the traditions of its early days, when churches, cathedrals and ruins were the main objectives of pictorial photography; and it is thus fitting that the ex-president, Dr. Rodman, contributes a view of ruins in "Ludlow Castle" (94). In modern days we show, perhaps, less sympathetic veneration for the past, as past; but more enthusiasm for its appearance under natural effects. It is this which gives us interiors with a mood like W. Archer Clark's "Ray of Sunlight, Ely" (138), A. Stephenson's beautiful study of light beams among arches and piers, called "In Softened Light the Sunbeams Pour" (119); likewise the illuminated courtyards, such as J. A. Lomax's "Sunlit" (49), a first-rate study, and "A Sunlit Courtyard" (53), taken from a shed, by Frank H. Read, with beautiful quality; and the strange circular doorway with light beyond in "From Cell to Courtyard" (86), by Dr. N. Hay Bolton. In street scenes, mention has already been made of one or two works; but the visitor should note G. Bellamy Clifton's "Old Bristol" (40), with its nice rich shadows; "The Pantiles" (32), by W. C. Squires; the highly picturesque "St. Goarhausen" (116), by Herbert Bairstow, a narrow street with a man and a child, and his "Filsen am Rhein" (126), where a woman is just entering the shade of an arch, both interesting in their gothic quaintness. F. G. Tutton turns to the classic with his damsel on a renaissance seat, "At the End of the Terrace" (109). Here good use has been made of the shadow that falls across the marble structure. Modern architecture shrouded in misty light, and seen behind the sharper pattern of slender tree-stems, is the theme of Miss C. Sipprell's "City Hall Square, New York" (98). As an exercise in composition with rectangular lines Lewis L. Banfield's "The Sunbaskers" (61) would be hard to beat. The big column at the back is most artistically receding and yet dominates the scene. As a tone-study also this work is very fine. Alfred J. Wood does well in getting the relative tones of a church, with lighted windows, against a night sky, which he calls "Light Amid the Encircling Gloom" (105), and a more pictorial attempt has been made by R. H. Bullen with "The Fox Inn, near Letchworth" (33), but I fear that it is too full of anomalies due to the artistic after-touch to maintain its interest after the first glance. To conclude with Horace Jackson's "A Chinese Tea Vendor" (43), we see how the lines of steps and awning have made a theme in composition emphasised by the darker tones of the shaded parts.

It is really a grand Exhibition, and this estimate was attested by Mr. Solomon J. Solomon, R.A. who opened it on Saturday last. He referred to the "splendid" composition of the subjects, and particularly pointed out the merit of the landscapes; as well as giving a tribute of praise to the effective display of slides and coloured transparencies in the rooms above. These are, indeed, shown this year to the best advantage. A notice of this sort should not conclude without a reference to S. Pegler's Autochrome stereoscopic subjects, of which there are two cabinets. Never before has the quasi-realism of stereoscopy—often a gross exaggeration of the third dimension—been given with so much convincing truth and surprise at its beauty; for the Autochrome becomes quite another thing in this method of showing. Mr. Solomon was enthusiastic about a certain picture of jewels and diamonds. He said: "They made my mouth water"—they would; but they are above my station in life. I yearned to be in "Sherwood Forest"; indeed, I felt I was there among the tawny bracken—a rich and restrained and yet brilliant scheme of colour.

F. C. Tilney.

THE TECHNICAL SECTIONS.

Examples of a process of producing accurate scales without the use of a ruling machine are shown by A. E. Bawtree (268). Mr. Bawtree uses a copying camera, double-toning, and expansion or contraction of a paper print as steps in his method of producing finely divided scales serving such purposes as conversion of weights and measures, thermometric scales, etc. The relation between the size and the number of grains in an emulsion is shown by curves (269) obtained by A. P. H. Trivelli and F. L. Righter from measurements which must have been extremely laborious. The recent researches of Loyd A. Jones

on the gloss of photographic papers are illustrated in No. 270, which shows four papers of different degrees of gloss, and, for each, the distribution of the light reflected from the surface. According to the definition of surface reflection adopted by Mr. Jones, the matt paper has a gloss of .92; the semi-matt, of 1.8; the semi-glossy of 4.1 and the glossy of 24.2. Dr. Sheppard, in some photographs (272) of the shapes assumed by cubes, spheres, etc., of gelatine when drying, illustrates the great strains set up in gelatine in process of dessication, as exemplified in the by no means uncommon phenomenon in which the surface of a glass plate is torn away by a contracting gelatine film. Photographs of the apparatus used for the measurement of the visible graininess of photographic negatives are shown by Arthur C. Hardy (273). An interesting illustration of the degree of definition obtainable in photographs of the surface structure of planets is shown by Frank E. Ross (274). The definition represents objects no larger than 1½ miles as they would appear when photographed with the Mount Wilson reflector telescope of 270 ft. focus.

The various forms of crystals of silver bromide occurring in dry-plate emulsions and in other silver preparations are shown by A. P. H. Trivelli (275-6), and are extraordinarily perfect photo-micrographs taken at a magnification of 3,000 diameters. These may be compared with a further series (374) by J. Willis Grundy of silver bromide grains from ammonia solution photographed at 1,000 diameters.

Some interesting examples of the photographic examination of forged documents are Nos. 356-359, by Wilfred Mark Webb, in the shape of reproductions of a Russian internal passport, showing the numerous falsifications which had been carried out for the purpose of use of the passport by others than its original holder. Unfortunately, no details of the method of examination are given. Mrs. M. Dickinson, in No. 300, shows a pair of photographs illustrating what appears to be a method of removing scale from boiler tubes by radio active material. The photographic interest is small, and the omission of any details of the process illustrated is, therefore, all the more unfortunate. The most notable examples of photographic methods of industrial research are the series of photographs (365-372A) by Philip P. Quayle, of the United States Bureau of Standards, showing the course of bullets through various materials.

Colour Cinematography.

Colour cinematography is represented by the single exhibit (387) of John G. Capstaff, illustrating the two-colour or Kodachrome process of the Eastman Research Laboratory. The film negative is taken alternately through red and green filters and a positive made from it. From this positive printing is done by a system of optical projection on to opposite sides of a double-coated film, the alternate images of the positive being thus produced as registering pairs of negative images, that is to say, one image of each pair is on one side of the film and the other on the other. This duplex negative film is bleached, fixed and converted by a reversal process of dye toning into a two-colour positive film, in which the red-sensation images are toned blue-green and the green-sensation images, red. The examples show the clearness and brightness of the films and the suitability of the process for close-up portraits.

Astronomical and Aerial Photography.

The astronomical and aerial sections of the Exhibition contain some excellent examples, clearly demonstrating the advance that photography has made in these difficult branches. No. 289, "Great Nebula in Orion," by the Mount Wilson Observatory, is worthy of praise. Other photographs of various nebulæ are Nos. 277-289, by Dr. J. S. Plaskett. "A Giant Group of Sunspots," No. 281, by the Astronomer-Royal, is interesting, and the "Unusual Spectra of Seven Stars," by the Mount Wilson Observatory, is difficult work well done.

Aerial cloud studies by F. W. Baker, F.R.Met.S., are fine work. His No. 282, "Strato Cumulus from 7,500 ft.," is a cloud landscape. Some illustrations of upper cloud formations by G. Aubourne Clarke show great care and study. Examples of aerial photography by J. Willis Grundy are worthy of notice, his No. 382 being especially interesting. Print No. 2 under this number demonstrates the value of a red-sensitive plate, and a naphtholdisulphonic acid filter.

Photo-Micrography and Radiography.

Much excellent work is shown in these sections, particularly noticeable being the rock sections, by C. H. Caffyn; his No. 300, "Six Sections of Calcareous Rocks," gaining the medal. Photo-micrographs of typical animal hairs, and hairs on leaves of plants, by Dr. G. H. Rodman, are extremely good, as also is his No. 306A, "Under Surface of Leaf of Goosefoot."

Amongst the radiographs will be found some fine work by N. E. Luboshey. The medal in this section has been granted to No. 332, "Sarcoma," by A. O. Forder. An interesting radiograph negative is shown in the Transparency room; it represents a fish which has swallowed a whelk.

Stereoscopic Photography.

The stereoscopic prints are the work of Messrs. Ralph Chislett and Oliver A. Weiss. No. 421, "Merlin and Young," by the former, is particularly noticeable. The stereoscopic transparencies by A. T. Mole should be seen, a group of old Dutch fishermen being especially good. Two cabinets of colour stereos in the Autochrome process, by S. Pegler, F.R.P.S., are interesting, No. 32, "Dessert," standing out well. In Cabinet No. 439 an Autochrome positive of a pot of flowers is shown, and also a negative in complementary colours of the same subject.

Lantern Transparencies.

The Royal Photographic Society is to be congratulated upon the improved method of displaying the colour transparencies and pictorial lantern slides. In past years one felt loth to enter this room, which was lighted by many incandescent gas lamps, and the temperature of which could only be likened to that of a Turkish bath. The present system, however, using direct diffused electric illumination, is a great improvement, and the transparencies and slides are shown to greater advantage. The large number of lantern slides which have been packed in the stand provided makes the viewing of them very difficult, and while there is some excellent work shown, some slides would have been better left out. Nos. 441 to 536 are a loan section by members of the Manchester Amateur Photographic Society selected by Jas. Shaw, and are not for competition. This collection includes some fine work, especially that by Mr. Shaw himself. His figure studies, Nos. 450 to 452, are particularly good. The snow studies by S. L. Coulthurst are well worth notice, as also are slides by J. D. Berwick and W. W. F. Pullen. Amongst the competition slides are several that badly require spotting, and some we noticed have been spotted in a red coloured pigment that does not look well on a dark toned slide. Some of the slides also are rather weak. The hand-coloured slides, although exceedingly well done, are quite out of place. Amongst the slides which stand out well in this overcrowded section are the set by Wm. Archer Clarke, Nos. 639 to 650. His No. 647, "The Shadow," gains a medal. Dr. G. H. Rodman shows some fine studies of dogs' heads, and Ranald Rigby's "Cut Glass" (No. 599) is good clean work. We admired the fine technique of Edgar R. Bull's slides of Penshurst, especially Nos. 666 and 667. A most interesting set of slides is included by J. Dudley Johnston, Nos. 686 and 687. The former represents 30 slides illustrating the factors governing colour in lantern slides when using a developer containing thiocarbamide, and the second set is of 10 slides showing the influence of variation of the thiocarbamide in the developer. These slides show the methods used by Mr. Johnston in his extraordinarily skilful practice of making lantern-slides of various quiet degrees of warmth of colour.

COLOUR TRANSPARENCIES AND PRINTS.

In the past one has never been quite certain whether the Autochromes and other colour transparencies were judged at the Royal on their pictorial or technical merits. This year they are definitely brought within the pictorial fold, and have been judged by a committee, charged, as we suppose, to make its awards purely on the basis of the æsthetic qualities of the exhibits. We daresay that they found that it is much more difficult to do this in the case of colour transparencies than in that of monochrome prints which are put forward as examples of pictorialism, and considering the very small opportunity, beyond selection of the subject, which there is for pictorial expression in the Autochrome process, it is greatly to be doubted if there is a real advantage in leaning towards this view of the process and definitely labelling other colour work as "scientific" simply because the subjects are of a scientific character. However this may be, a medal has been awarded to an Autochrome study of still life (766), by Bertram H. Saunders, entitled "A Good Dinner." It is quite a good dinner, including a pheasant, trussed fowl, joint of beef, and many pounds of vegetables, and we commend the reserve of those who arranged the transparencies for placing a study by the same author of dessert fruits in quite another part of the collection. The judges must have had a good deal of difficulty in deciding between "A Good Dinner" and the Autochrome "Neapolitan Type" (695), by N. E. Luboshey, which technically, we think, is a much better example of the process, and pictorially at least as good. Another medal is awarded to F. G. Tutton for a three-colour transparency of still life (706) by the carbon process, in which the colours have been strengthened with dyes.

This year the flower and fruit transparencies by Henry Irving are again of extremely beautiful quality, though perhaps not superior to those of last year. His best, we think, is No. 696, of sweet peas. Most of the landscapes do not rise above the ordinary, but there is a beautiful study of birch and bracken, "Autumn Gold" (713), by Henry E. Harris; another, "Heather" (776), by W. Scruton; and a fine series of Corsica (783-790), by Major T. W. Bartlett and Miss E. M. Bartlett.

When we come to the colour prints we are bound to say that, in our opinion, the presumed policy of judging the work as part of the pictorial exhibits has proved a mistake. In the present state of the technique of making colour prints on paper every encouragement should be given to the production of work which marks a technical advance as regards registration, purity and brilliance of colours, absence of predominant tints, and other qualities which in the past it has been so difficult to overcome. The pictorial application of the technical methods may very well be left to itself for a while. Thus, while the "Figure Study" (392) in the three-colour carbon process, by Leo. G. Nicoll, who receives a medal, has many pictorial merits, this single award undoubtedly overlooks the remarkable progress in the making of three-colour prints by the Raydex method exhibited by Samuel Manners in Nos. 396-402, all of which mark a great advance in the technique of this method, which Mr. Manners has long worked to perfect. Even the hanging committee seem to have had a grudge against them, for they have put them on the dark side of a screen where they cannot be properly seen. These exhibits by themselves make the colour-print section the best which the Society has had for many years. The others do not make a very strong show, although Commander H. E. Rendall has a very pleasing version of sunshine and colour in No. 413, "The Gardens of Villa Frere, Malta," also by the Raydex process.

THE P.P.A. CONGRESS.

The concluding portion of the reports of the crowded week of fixtures arranged by the Professional Photographers' Association for the recent Congress appears below. Owing to the considerable number of the papers and demonstrations which formed the programme, we have had to abandon a datal order of the proceedings, but all the fixtures have now been dealt with in our pages. The Congress came to an end with the installation, at the dinner, of Mr. Alexander Corbett as President of the Association for the current year. Elsewhere in this issue appears a key to the members who figured in the Congress group reproduced last week.

UNUSUAL PORTRAITURE.

On the Wednesday evening of Congress week the lecture was by Mr. Charles Aylett, of Toronto, whose subject was "Unusual Portraiture, introducting Spot Lighting and Soft-focus Lenses." The chair was taken by Mr. W. L. F. Wastell, President of the Royal Photographic Society.

Mr Aylett said that it had been an eye-opener for him and for his colleague, Mr. Kennedy, to see the present exhibition. He had no idea that such wonderful and beautiful work was produced on this side. He had seen a few photographs of British origin at Conventions in the United States—not so often in Canada—and they had always been of a very high standard, but he had "figured" that these were by men who were advanced amateurs and were made for exhibition purposes. Now he understood that it was everyday work, and he could not help congratulating the Association upon the finest exhibition of portrait photographs he had ever seen, and he had seen a great many, having attended at least five Conventions in the United States and Canada this year.

The average picture they got in the States and in Canada was just that "honest to God sort of photograph, don't you know," which had every technical excellence, but the pictures in this exhibition showed him that their producers were aiming at the ideal. Many of the pictures, and particularly the one that had won the first prize, had a mystery about them and a harmony which was very often absent from the pictures on "the other side," good as they were. He went on to speak about the value of Congresses. Their supreme value was in the opportunity they afforded one to know one's fellow photographers. In their atmosphere all unwarranted jealousy disappeared. If any of them had any new device or process or idea he was very glad to demonstrate it to someone else. They liked to show it to the man round the next block. He would not imitate it, or, if he did, he would not do it in exactly the same way. And if he worked out something a little different it helped him along, and did not do his colleague any harm. All of them could show one another new ways of doing things, although for his own part, he dipped his pennons to British photographers, and seriously doubted, after seeing their exhibition, whether he could show them anything in particular. He was supposed to talk about soft-focus lenses. He used soft-focus lenses every day in the week in his studio, and had done so for the last eight years. He believed in soft-focus lenses. He did not think that soft-focus lenses were a fad. They were something which had come to stay. They gave him, not so much a photograph of some hair, as an impression of hair. The things looked real to him as seen by the soft-focus lens. He had made more money by the use of soft-focus lenses than by the use of anything else. He would never have been able to come over to England had it not been for soft-focus lenses. When he told them about the rewards to be made in Canada from the use of soft-focus lenses, he rather expected that all the men using soft-focus lenses would be coming over to the Dominion pretty soon. The results with the soft-focus lens approached nearest to brush effects He did not think that their sitters or their sitters' friends wanted to see the hard drawing, the wiry portrait. They wanted to feel that the resemblance portrayed the spirit of the person concerned. The spirit could not be put on paper, but something of its subtlety and softness could be caught, so that another person, looking at the portrait would say, "That is mother! That is father!"

referring not to the contour of the features, but to the suggestion of the personality, and this could best be given by the soft-focus lens.

Mr. Aylett then went on to explain that Mrs. Aylett would act as his model that evening. An installation of Osram gas-filled lamps had been fitted for him, together with a black felt ground and a white felt ground, one or other of which he always used. A necessary property was a Paisley shawl, which he used as a screen. Coming over to London he had imagined that such a shawl would be readily procurable, only to find out his mistake. However, in Oxford Street, he had managed to get some kind of a substitute. He was accustomed to use, with his black felt ground, a small 300-watt lamp behind the subject. The lighting installation on this occasion was not quite that to which he was accustomed. The light behind the subject in this instance was 1,000-watt lamp, and he had to make special arrangements to tone it down with paper screens to somewhere about the equivalent of a 300-watt lamp in a bulb-shaped reflector. This served to cut out the light from the subject, and reflected on to the background, giving him a little corner of illumination on the dark felt. He thought that this was a point worth remembering. On looking at the lighting scheme of most of the painter artists it would be observed that if they were using a dark ground, one corner would be lighter than the other three, and if they were using a light ground, one corner would be darker than the other three. By his method of using a small light in a bulb-shaped reflector and throwing this light on to his dark background, he obtained such an illumination behind his subject as made his subject and his background more completely one. The subject no longer stood out from the background. He did not like the subject to stand out; he liked the subject to stand in and to belong to the background. To him, at least, there was a feeling of unpleasantness if the subject jumped out at one, though he could not offer any scientific argument in defence of his taste in this respect.

In addition to this light behind the subject he had two other lamps on the opposite side of the subject, and slightly in front. These were subdued with white paper screens. Some light muslin was stretched at one side—the side of the single lamp—and on the other side some darker fabric or the Paisley shawl; and the sitter herself was dressed in black hat and cloak. Mr. Aylett said that he would try to work as he worked at home, although allowance must be made for somewhat different conditions. He used, of course, his soft-focus lens, remarking that he had at least seven or eight soft-focus lenses, and every few months he came upon the best lens of the kind he had ever used, only to discard it later in favour of another, which really *was* the best. He always worked in a very low key, and he agreed with what the President had said in his address from the chair about the value of long exposures. He never tried to make snapshots in the studio, but quite customarily gave up to three or four seconds. With a long exposure one was more likely to get a composite expression, furnishing a better indication of character. In making a three-quarter portrait of a sitting figure he always crossed the knee that was closest to the camera. It was a disputed question whether the eyes should be made to look directly into the lens. He did not himself make many pictures in which the eyes looked into the lens. He knew one photographer in the United States, who told him that his business amounted last year to 110,000 dollars, who rarely made a picture in which the eyes "did not look bang into the lens"; he said that such pictures always sold, but the speaker's own preference was for the eyes, at least very frequently, to be turned away. Mr. Aylett at this point in his demonstration, when about half-a-dozen members of the audience were assisting him in his arrangement of screens, or in suggesting poses for his model, remarked that the plenitude of assistance rather embarrassed him; he had never had an assistant in his life and had done all his work himself.

With regard to spot lighting—which he always preferred to call back lighting—this was an element which should be introduced only in carefully selected subjects. There were occasions when its use was quite legitimate, but it had been overdone and abused. He himself only used spot lighting or back lighting, just to give a little "snap" when this seemed to be necessary. He always worked the spot lighting or back lighting as close as he could without getting the beam shining into the lens. With the aid of a projection lamp held behind the sitter, on the opposite side to the single lamp for illuminating the background, he showed various spot light effects, demonstrating how an interesting line of light could be made to run up one side of the face, or to add by some other stratagem to the interest of the profile. He rarely used the spot light on ladies who had dark hair. The best subjects for this treatment were those whose hair was fair and soft and fluffy. With dark hair there was apt to be a "splashy" effect. It was also very necessary not to make this particular light effect too continuous. It should not be made to surround the profile, but only to appear here and there and be lost again. It needed very delicate manipulation, otherwise it might suggest something which had been cut off with a razor.

Mr. Aylett made one or two exposures with a large studio camera, remarking in doing so that he never exactly timed his exposures; "you just feel that it is right." Subsequently he abandoned the camera, so that the audience could better see the effects, and tried various schemes of posing and lighting, in particular pointing out how the 300-watt lamp behind gave relief and interest to one side of the picture. He also tried some effects with a white background with the Paisley shawl across a large corner of it. Sunlight and pleasant shadow effects, not too brittle in line, were thus secured.

It must be added that the interest of the compositions was greatly assisted by the singularly beautiful model, and Mr. Aylett recalled the remark of Snowden Ward, that a good photograph must be something beautifully photographed, and not merely the photograph of something beautiful. But they well knew that 50 per cent. of the success in photography was attributable to the original beauty or distinction of the sitter. Beautiful photography could certainly be done on someone who was not prepossessing, but how many of the photographs now on the wall would be hung were it not for the beauty of the living original? He concluded by saying how amply he had been rewarded for his trip across the Atlantic, and how glad he would be to feel that he had helped anyone.

At the close of the lecture the Chairman proposed a vote of thanks. Alluding to the many members of the audience who had rendered Mr. Aylett assistance by holding draperies or shifting the camera, he said that he had never in all his life seen so many professional photographers on their knees. (Laughter.) He had himself learned a great deal. He had learned why he could never take portraits. His methods both in posing and in lighting were more casual, and he was afraid that none of the sitters to whom he was accustomed would exhibit the patience of the very beautiful and attractive model whose services Mr. Aylett had been fortunate enough to command.

The vote of thanks was carried with acclamation, and Mr. Aylett, in reply, said that this was the proudest day in his life "since the day I married her."

The President (Mr. Swan Watson) expressed thanks to Messrs. Houghton's, Ltd., for the loan of apparatus, and to the General Electric Co., Ltd., for the loan of lamps, and the services of their representative, Mr. Rondle. Then, without the presence of the President of the Royal Photographic Society and his humour and good sense, they could not have had quite such a happy evening, and he wished him, in the name of the Association, a most successful year of office.

During the evening Mr. Kennedy read a letter he had received from Mr. Howard D. Beach, of Buffalo, New York, immediate Past President of the National Photographers' Association of America, who hoped to visit London at the next Congress. One sentence of his letter ran: "Take to the boys of the Congress the best wishes of the Buffalo Section No. 6 of the P.P.S.N.Y. for a great meeting and subsequent prosperity for all." (Applause.)

STATUTORY GENERAL MEETING OF THE ASSOCIATION.

The Statutory General Meeting of the Professional Photographers' Association of Great Britain and Ireland, Limited (adjourned from March 10, 1922), was held at Princes Galleries, Piccadilly, London, on Friday, September 15, 1922.

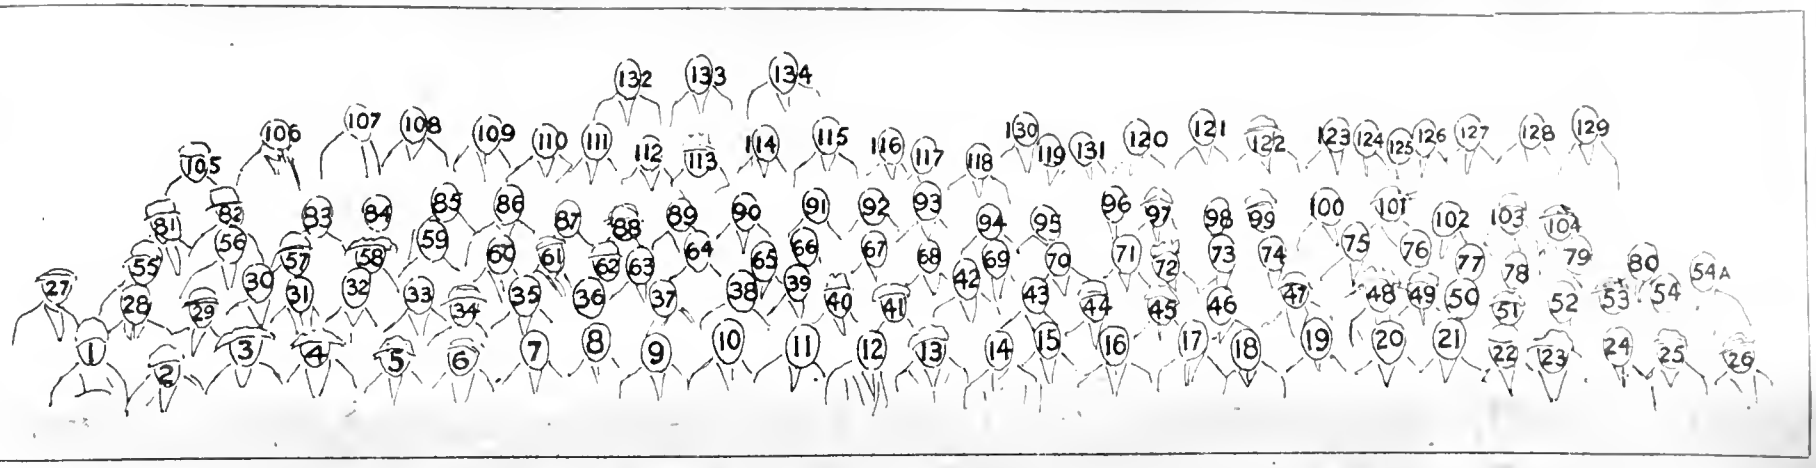
Mr. A. Swan Watson (President) was in the chair, and about sixty members of the Association were present.

The Secretary (Mr. Alfred Ellis) having read the notice convening the meeting,

The President explained the purpose of the meeting, which was to complete the business of the previous General Meeting of March 10, when the Statutory Report and the General Report of the Council and the Treasurer's Statement of Accounts were adopted.

On the motion of Mr. F. Read, seconded by Mr. Mills, it was agreed that these reports should be received. The report of Council since the adjournment came up for adoption subsequently.

The President said that only one nomination had been received



THE P.P.A. CONGRESS.—KEY TO THE GROUP REPRODUCED IN THE "BRITISH JOURNAL OF PHOTOGRAPHY," OF SEPTEMBER 22.

1. Mrs. F. Brown, Leicester.
2. Mrs. Maud Basil, London.
3. Mrs. Gordon Chase, Bromley.
4. Mrs. Speight, Nuneaton.
5. Mrs. J. C. Harper, Leith.
6. Miss Illingworth, Northampton.
7. F. Read, Liverpool.
8. A. H. Ll. Chapman, Swansea.
9. W. Illingworth, Northampton.
10. George Hana, London.
11. Frank Brown, Leicester.
12. Pirie Macdonald, New York.
13. Mrs. Swan Watson, Edinburgh.
14. A. Swan Watson, Edinburgh.
15. Alfred Ellis, London.
16. A. Corbett, London.
17. R. N. Speaight, London.
18. Gordon Chase, Bromley.
19. F. Wakefield, Chiswick.
20. W. Wedlake, London.
21. T. Chidley, Chester.
22. W. E. Gray, Bayswater.
23. Mrs. W. E. Gray, Bayswater.
24. C. F. Dickinson, Dulwich.
25. Mrs. C. F. Dickinson, Dulwich.
26. Mrs. Herbert Morle, Perth.
27. E. J. Short, Nottingham.
28. G. J. Hughes, Bridge of Allan.
29. A. Clara Cooper, Birmingham.
30. H. J. Whitlock, Birmingham.
31. N. G. Devare, Bombay.
32. R. L. Speaight.
33. H. Harrison, Bow.
34. E. A. Harrison, Bow.
35. A. Eddison, Barnsley.
36. Mr. Durant, Barnsley.
37. Clare Speight, Nuneaton.
38. J. W. Stocks, Uppingham.
39. Oscar Owers, Southsea.
40. W. H. Duncan, Hull.
41. Mrs. W. H. Duncan, Hull.
42. James Maclachlan, Wishaw.
43. James Nimmo, Ayr.
44. Mrs. James Nimmo, Ayr.
45. Mrs. Wakeling.
46. A. W. Wakeling.
47. Mrs. F. Wakefield, Chiswick.
48. Mrs. W. Wedlake, London.
49. Mrs. Vanderbilt, Liverpool.
50. J. R. Saronie, Liverpool.
51. Mrs. J. R. Saronie, Liverpool.
52. H. Bentley, Barrow-in-Furness.
53. Mrs. H. Bentley, Barrow-in-Furness.
54. S. W. Pritchard, Lochee, Dundee.
54A. W. B. Chaplin, Windsor.
55. L. Croad, Southsea.
56. T. W. Clark, Forest Gate.
57. Mrs. H. Evans, Plaistow.
58. Mrs. Shotter, Plaistow.
59. J. C. Brown, Falkirk.
60. J. Campbell Harper, Leith.
61. Mrs. Haines, East Sheen.
62. Miss Brown, Inverurie.
63. T. R. Hammond, Conway.
64. E. E. Carter, Romford.
65. W. Edwards, Romford.
66. C. S. Harris, Dover.
67. A. O. Forrest, Pontypridd.
68. L. Ladd, Tonypandy.
69. Dan Osborne, Treharris, S. Wales.
70. Chas. Hopp, Detroit, U.S.A.
71. J. D. Chambers, Newark.
72. Mrs. J. D. Chambers, Newark.
73. C. Wilson, Lowestoft.
74. J. Dickinson, Newcastle-on-Tyne.
75. E. J. F. Leatherby, Plymouth.
76. T. P. Cummings, Warrington.
77. R. H. Gresswell, Southport.
78. W. H. Huish, Manchester.
79. J. Edwards, Oldham.
80. Lang Sims, Brixton.
81. Archer Clarke, London.
82. E. G. Shapper, Barking.
83. A. M. Scott, Kodak, Ltd.
84. J. L. Newman, Kodak, Ltd
85. W. H. Brown, Weston-super-Mare.
86. E. J. Edwards, Birmingham.
87. H. Trevor Jessop, Exmouth.
88. Mrs. H. Trevor Jessop, Exmouth.
89. Wilfred, Jenkins, South Kensington.
90. G. B. Towner, Uckfield.
91. G. H. Wakefield, Hanwell.
92. H. Hall, Wakefield.
93. W. E. Bull, Witham, Essex.
94. Alfred Houper, Watford.
95. T. Lee Syms, Tyldesley.
96. G. Cowley, London.
97. Mrs. G. Cowley, London.
98. D. Garner, Stockport.
99. Mrs. D. Garner, Stockport.
100. T. A. Scotton, Derby.
101. Miss Methwen-Brownlee.
102. G. J Heaton, London.
103. Miss S. Weston, Northwood.
104. Miss Daisy Day, Bishop's Stortford.
105. Miss Alicia Wicks, London.
106. J. Charlton, Canterbury.
107. H. Lawrence, Kodak, Ltd.
108. A. G. Webb, Kodak, Ltd.
109. G. N. Futcher, Southsea.
110. R. M. Watt, Dundee.
111. W. H. Thomas, Melbourne, Australia.
112. E. V. Bowles, Dover.
113. Mrs. E. V. Bowles, Dover.
114. J. S. Simnett, Burton-on-Trent.
115. Archer Argent, Kensington.
116. F. W. Vidler, Willesden.
117. A. Handford, Croydon.
118. A. W. Dron, Brondesbury.
119. A. J. Anderson, Leighton Buzzard.
120. W. Longman, Cheltenham.
121. E. C. Moxon, Folkestone.
122. Mrs. Butt, Bourton-on-the Water.
123. W. J. Butt, Bourton-on-the Water.
124. S. A. Chandler, Exeter.
125. A. Bennett, London.
126. T. E. Notcutt, Plymouth.
127. W. Wade, Middlesbrough.
128. J. Bamber, Blackpool.
129. C. S. Downing, Elstree, Herts.
130. A. F. Loveday, London.
131. E. F. Gilbert, London.
132. Jack Thomas, Swansea.
133. Norman Bunting, South Bank, Yorks.
134. E. Milner, London.

Photographic copies of the group are obtainable from Mr. W. B. Chaplin (J. Russell & Sons), Windsor.

for the presidency—namely, Mr. Alexander Corbett—and, therefore, no ballot would be necessary, and it only remained for the meeting to signify its approval of the choice.

The meeting did so by acclamation, and Mr. Corbett expressed his thanks for the honour done him.

The President said that Mr. R. N. Speaight was the only nomination for the treasurership, and he asked the meeting to approve his election. (Loud applause.)

Mr. Speaight thanked the members.

The President said that there were only four nominations for the four vacancies for London members of the Council—namely, Messrs. A. Basil, R. Haines, G. Hana, and Lang Sims—and, therefore, no ballot would be necessary. For the vacancies for four country members there were six nominations—namely, Mr. F. Brown (who now terminated his *ex officio* membership of the Council as Past President), Mr. W. B. Chaplin, Mr. G. N. Futcher, Mr. F. Read, Mr. H. C. Spink, and Mr. W. H. Wedlake. A ballot would, therefore, be necessary.

Mr. Wilson and Miss Brownlee were appointed scrutineers.

The ballot having been taken, the President declared the following had been elected:—Messrs. F. Brown, W. B. Chaplin, H. C. Spink, W. H. Wedlake.

Mr. Archer Clarke then proposed that Messrs. Norton, Slade & Co. be reappointed auditors at the usual fee of ten guineas, and Mr. N. G. Devare (Bombay) seconded.

Mr. F. W. Vidler said that ten guineas was a large fee in view of the comparative smallness of the Association and the simplicity of its finance.

The President said that his own experience was that this was quite economical auditing.

Mr. Speaight pointed out that the Association was a newly-started company, necessitating quite a considerable scheme of book-keeping, and the accounts for the "Record" were a complicating factor. He personally thought the amount an extremely reasonable one for the work entailed.

Mr. W. H. Huish also thought the sum a very modest one.

Mr. Speaight added that financially the Congress was likely to prove better than any of them had anticipated. On the Council they would not have thought it extravagant if they had had to dip into their reserves to meet the expenditure on what was a magnificent advertisement, but it seemed likely that the balance would be on the right side.

The motion reappointing the auditors was then agreed to without dissent.

Mr. A. Barrett then moved the adoption of the report of the Council since the adjournment of the Annual General Meeting of March 10, and drew attention to the fact that very little mention had been made in the report about the Exhibition, and this only showed how modest the members of Council were with regard to their own labour and achievements.

Mr. Wilson seconded, remarking that the work of the Council had been the work of giants.

The motion was agreed to unanimously.

On "Other Business,"

Mr. W. H. Huish apologised for certain Lancashire friends who had been obliged to leave London before the termination of the Congress. A territorial Association had been formed in the North of England four years ago, and was a very live body, but he desired to make it plain that its supporters were equally loyal members of the national association. On the other hand, these local or territorial associations did an enormous amount of good in their areas, and he thought their formation should be encouraged throughout the country. This would save the trouble and expense of devolution. Up to now the Association in London had been able to carry on in a very quiet and unassuming way, but in the years to come it might find such territorial associations affiliated to its own body of very great value and support. He wanted to know how such associations were affiliated, and whether they paid a fee, and whether they had direct representation on the Council. The society for which he spoke was quite prepared to consider the question of an affiliation fee. It did not want merely to think of itself as affiliated; it wanted to be a definite part of the Association. If it paid its quota it should have representation on the Council. On another occasion he trusted the President might give some enlightenment on this subject.

The Secretary said that at the present time the Council had not gone sufficiently far into the matter to ask for or accept any affiliation fee from the societies. Any help which could be given on matters which concerned the whole of the members, the Association was only too pleased to give, expecting in return that should it have any trouble in a particular locality covered by one of these bodies similar help would be given there. It was his desire to form a society in every county in the kingdom, and he hoped he might be spared long enough to carry that through. Originally the idea was to have branches in every town, but local rivalries were an impediment; this would not hold good in the larger area of a county.

Mr. A. Barrett moved:

> That this meeting express its deep appreciation of the painstaking work accomplished by the officers and members of Council of this Association during the year; also that this meeting place on record its indebtedness for the hard work that has been done by all concerned to make the great International Exhibition such a tremendous success.

He drew attention to the excellencies of the Exhibition and the Congress, and also to the great publicity which it had received. "The Times" and other papers had been very generous in their notices, and the provincial Press had also done its share. The publicity secured was a testimony to the efforts of the Council.

Mr. Oscar Owers seconded. The private members of the Association had only a vague idea of the tremendous amount of work put in by the officers and Council, but they appreciated it exceedingly. He wished to say how very gratefully he valued the high, idealistic, almost religious tone of some of the events of the Congress. Everything arranged for that week had been of the very first order.

Mr. W. H. Huish, on behalf of Lancashire, wished to associate himself with this vote. He looked upon the Exhibition and Congress as a most wonderful achievement. The Council was to be highly congratulated all the way through. The outing on the previous day had been one of the happiest he had ever enjoyed. There was only one point of smallest criticism. He hoped that another year the Annual Meeting and dinner would not be relegated to the last day, by which time some of the members had had to leave.

Mr. A. C. Forrest, as a humble representative from the gallant Principality, added his appreciation of the work so well and thoroughly done. When he read of the long hours of the Council meetings he was lost in astonishment to think that so many men could be found to come together and give so much valuable time.

Mr. J. Nimmo said that those from Scotland endorsed all that had been said. The Scot was seldom exuberant in his appreciation, but he felt it all the same.

The motion was then put to the meeting by Mr. Barrett, and adopted with loud applause.

The President said that in the course of their lives most of them had done many things for which they had received no reward, but this was altogether the other way.

In reply to a member who asked whether it was not possible to have the Congress earlier in the year, the President said that all other possibilities had been explored by the Council, and that the galleries could only have been secured conveniently in September, which, although inconvenient to some, was convenient for many members.

Mr. Marcus Adams suggested that next year the Congress should be held in Edinburgh, while Mr. A. L. Chapman put in a word for South Wales. Mr. Speaight said that he feared these suggestions were not practical. The Congress next year, which would be a bigger one than this, would involve a great number of committee meetings, etc., which could not be worked outside London. It was not a case of a mere Convention, but of a very large Exhibition, involving a great amount of local labour.

This concluded the business of the meeting.

THE ANNUAL DINNER.

The 21st anniversary dinner, which took place at Prince's Restaurant on the Friday evening, was a very happy "wind-up" of the Congress. It had a distinct Scottish flavour, alike in the decoration of the tables and the presence of a Highlander, who perambulated them with the pipes. Mr. A. Swan Watson presided, and the principal toast, that of the Association itself, was proposed by Mr. W. L. F. Wastell, President of the Royal Photographic Society. All the speeches were brief, Mr. Wastell's quite disappointingly so, but, as he declared, there was no need to dilate upon the value of the Association or the reasons for wishing it success and prosperity.

Mr. Swan Watson said that the Congress had been the largest

and most influential the Association had ever organised. He had not the slightest idea until he actually got to London that the exhibition was on so large and important a scale. He added that the Congress was made still more memorable by the presence of visitors from the United States, Canada, Australia, India, and Sweden. The past year had been marked by great activity in the Association, especially by the incorporation and by the establishment of the "Record," and there were many other activities ahead.

Mr. R. N. Speaight proposed the "Health of the Visitors," whom he preferred to call the friends. He read telegrams from "Annie and Jack Kennedy" and "The Ayletts," who had had to leave to catch their boat for Canada, both conveying much appreciation for kindness shown them during their stay.

Mr. Pirie MacDonald aroused laughter by giving his speech in the style of a military report, to the effect that the Canadians had withdrawn under the heavy fire of British hospitality, and, as for himself, he was compelled to retreat in the morning, and within 24 hours his vessel would have her nose pointed for Sandy Hook. There was one fly in the amber. The man most responsible for the fellowship between British and American photographers—Reggie Haines—was ill in bed. He called upon the gathering to stand and drink the health of Mr. Reginald Haines, which they did with a very good will. Mr. Macdonald concluded his speech by saying that the Americans were the greatest people in the whole world for using "pep"; the English had it, but they did not use it. He called on the company to repeat after him, "I want what I want when I want it," and this was done, with many resounding bangs on the table.

Mr. Brooke, formerly of Sydney, also replied to the toast. He was sorry to see that Australia was not represented in the exhibition, and would endeavour to repair the omission on a future occasion after his return. He was, however, enjoying a brief (!) holiday, and would not be resuming work until January 1, 1924.

The President at this point read a telegram from Mr. Flodin, of Stockholm, "Three cheers for the P.P.A."

Mr. F. G. Wakefield took occasion to thank the trade exhibitors for their support, and with him gratitude was an expectation of favours to come; next year the trade exhibit would have to be on a much larger scale.

Mr. R. E. Carter acknowledged the compliment, and said that the exhibitors were grateful for the untiring efforts of the Council and for the support of the members.

Mr. Marcus Adams proposed the toast of "The Press." The Press was one of the best friends of the Association. During the Congress something like 50 notices had appeared in the daily journals. When the Association developed its co-operative advertising scheme the Press would be more than ever their great standby. He thanked the photographic Press in particular for its support, mentioning Mr. T. Bell, editor of the "Professional Photographer"; Mr. Child Bayley and Mr. F. J. Mortimer, editors of the "Amateur Photographer and Photography"; Mr. G. E. Brown, editor of the "British Journal of Photography"; and, of course, Mr. Jenkyns Griffiths, editor of their own "Record."

Mr. Child Bayley, in response, said that the P.P.A. was particularly associated with amateur photography, because the Association incorporated the successful professional photographers, and these were essentially men who had the amateur spirit—that is to say, they loved their art, and the fact that it was their livelihood was a subsidiary matter. He also mentioned that the highest award in the British section of the Exhibition was taken by two ladies who were certainly amateurs, whether professionals or not. He recalled that on a previous occasion he alone had had to answer for the Photographic Press, because Mr. G. E. Brown was in ill-health. They were glad to see Mr. Brown back among them on that occasion. (Applause.)

Mr. G. E. Brown said that the gentleman who ought to reply to this toast was Mr. Griffiths, the Association's own editor, who had a rotten job. (Laughter.) There were two honorary editors, whose job was also rotten, and poor Mr. Griffiths had not only to please these two honorary editors, but the several members of the Council. If he might offer advice he would suggest that this editorial system was impossible, and that Mr. Griffiths ought to have the entire responsibility. The whole Photographic Press welcomed the appearance of the "Record" and wished it every success. The Photographic Press also rejoiced in the success of the Congress. The Council had wrestled with difficulties that might have seemed insuperable and had brought off a good thing.

Mr. Arthur Webb proposed the toast of the "Officers and Council," who deserved the gratitude, he said, of the general body of members. Mr. Angus Basil suitably replied in a few sentences, and said that next year big schemes had been suggested to them, and they would have to call upon more outside help.

Mr. Frank Brown proposed the "Health of the President." They had learned not only to respect Mr. Swan Watson, but to love him. His kindness had shone throughout the week, and he carried with him into retirement the best wishes of them all. (Loud applause.)

Mr. Swan Watson said that his year of office had been one of great enjoyment, thanks to the courtesy shown by his colleagues. He regretted that one of the members of the Council to whose unfailing optimism they all owed much—Mr. Reginald Haines—was away ill. Mr. Haines had sent a very nice letter, one sentence of which ran: "I stated at Buffalo last year that the members of the Convention visiting our Congress would meet with a great reception, and I wish to thank all our members, and especially my colleagues in the Council, for so loyally 'waking up' to this Congress." The President also read a telegram of greeting from the Photographic Society of Stockholm, and a telegram from Mr. Luboshey, "Kindest greetings to brother photographers. They should not be at daggers drawn."

The President then invested his successor, Mr. Alexander Corbett, with the badge of office, amid loud applause, and Mr. Corbett, in return, invested Mr. Swan Watson with the ex-President's badge.

Mr. Corbett said that he had a very difficult task indeed to follow the tradition set by Mr. Watson. Next year the Association looked forward to still greater things, and he hoped the manufacturers and dealers would give them still more support. The time had come when the manufacturers and dealers and themselves might meet at a round-table conference once or twice a year. He ended by proposing the health of Mr. Alfred Ellis—the man behind the gun. (Applause.)

Mr. Alfred Ellis said that he was only resuming a position which he first occupied when the Association was started 21 years ago. It was never his wish to leave that position, but he was made President, and could not fill the two offices. His best endeavours would be to promote the interests of the Association, and he hoped to see many hundreds, if not thousands, of new members. (Applause.)

During the evening a very fine musical programme was carried out under the direction of Mr. Herbert Lambert and the Secretary. Musical items were rendered by Miss Hebe Simpson, Mr. Lloyd Huwe, Mr. Ranger, and Miss Dorothy Glover's Trio (Miss Glover, Miss Elsie Barnard and Miss Maud Lucas). It was well after eleven before the company rose.

R.P.S. EXHIBITION LECTURES.

THE following lantern lectures will be delivered during the annual exhibition of the Royal Photographic Society, which will be open until Saturday, October 28:—

Friday, September 29.—Exhibition Lantern Slide Night. The slides selected for the exhibition will be shown on the screen.

Tuesday, October 3.—Lantern Lecture. "Lourdes." T. H. B. Scott, F.R.P.S.

Friday, October 6.—Lantern Lecture. "The Beginnings of London." Frank Lambert, M.A., F.S.A.

Tuesday, October 10.—The Twenty-fifth Annual Traill-Taylor Memorial Lecture: "The Development of the Photographic Lens from the Historical Point of View." Dr. Reginald S. Clay.

Friday, October 13.—Lantern Lecture. "Carcassone and the Pyrenees." Dr. C. Atkin Swan.

Tuesday, October 17.—Lantern Lecture. "The Progress of Aerial Photography." Major F. C. V. Laws.

Friday, October 20.—Lantern Lecture. "Recent Work in Cloud Photography." G. Aubourne Clarke.

Tuesday, October 24.—Lantern Lecture. "Some Landmarks of Ancient Egypt." E. W. Mellor, J.P.

Friday, October 27.—Lantern Lecture. "Familiar Flowers in Monochrome." Dr. G. H. Rodman.

COLOUR BY DEVELOPMENT IN LANTERN SLIDE MAKING.

Two sets of lantern slides, illustrating the factors governing colour, when using a developer containing a solvent of silver halide, and the influence of thiocarbamide in the developer, are shown at the Exhibition of the Royal Photographic Society, by Mr. J. Dudley Johnston. The greatest interest attaches to this exhibit, as some interesting tones are shown, and the developer is an improvement upon one suggested in the first edition of a booklet upon lantern slide making published by Messrs. Wratten & Wainwright. While some of the colours will not be admired, others cannot fail to please, and with the details of the experiments before him, the slide maker should be able to obtain some fine results. We have examined the slides carefully, and have given a name to the colour of each, as it appears to us. It is rather unfortunate that the slides are placed so close together, especially as the difference in colour of some of them is so slight, but by covering up the slides nearest to the one under examination a good idea of its actual effect was obtained. To our mind the best slide in the two sets is No 1. series 7a. This is in a beautiful warm chocolate colour very luminous and of excellent density, eminently suiting the sea and mountain subject. Another good slide is No. 1. Series 6, which is also a warm chocolate brown. We quote the full particulars of the process, and Mr. J. Dudley Johnston's remarks for obtaining these slides from the Exhibition Catalogue of the Royal Photographic Society, with the addition of the colour table added by ourselves. We have also noted the slide we consider the best in each series.

Exhibit No. 686 represents a set of 30 slides illustrating the factors governing colour in lantern slides when using a developer containing a solvent of silver halide. This exhibit is designed to show the influence of the different factors—exposure, temperature and developer—on the colour of the slide, and is arranged in 6 series of 5 slides each. The middle slide of each series, viz., No. 3, represents the normal, and each of these six slides received the same exposure, and was developed with the same developer at the same temperature. The results should therefore be identical. They show, however, some slight differences due to having been developed to different densities. This is due to the fact that development has to be gauged by appearance, as Mr. Johnstone has been unable to evolve any factorial system that would ensure uniformity owing to this developer being so extremely sensitive to slight variations of temperature and to other conditions (possibly the electrical state of the atmosphere) which are at present obscure. No doubt varying conditions of the electrical supply may be one of the contributory causes to a lack of uniformity.

The first task was to determine the correct exposure for the normal slide (No. 3 of each series) when using the developer designated X at the middle temperature, viz., 70°. This exposure is expressed as 1. In the case of these experiments, it was, as a matter of fact, 30 seconds at three feet from an Edwan Fullolite 90-watt lamp at a nominal voltage of 210.

The developers were made up from three solutions A, B, and C, as follows:

FORMULÆ.

A.—Metol		44 grs.
Hydroquinone		30 grs.
Soda sulphite anhydrous		240 grs.
Soda carbonate anhydrous		300 grs.
Water		20 grs.
B.—Ammonium carbonate		1 oz.
Ammonium bromide		1 oz.
Water		20 ozs.
C.—Thiocarbamide		33 grs.
Ammonium bromide		11 grs.
Water		10 ozs.

Five different combinations were then made up for use.

Developer T consisted of	6 parts A,	1 part B,	1 part C.
W	6	1	1
X	6	1½	1
Y	6	2	1
Z	6	2½	1

Series 1 shows the effect of Temperature alone.
2 " " Exposure alone.
3 " " Developer alone.
4 " " Temperature and Developer varied inversely.
5 " " Temperature and Exposure varied inversely.
6 " " Exposure and Developer varied inversely.

No attempt was made to obtain exact compensation between the factors in Series 4, 5 and 6. The effects shown are those of purely arbitrary ratios to cover a wide range of possibilities.

Series 6 comes nearest to showing what happens in actual practice when making lantern slides by this process.

DETAILS OF THE EXPERIMENTS.

Slide.	Exposure.	Developer.	Temperature. Degs.	First appearance of image. Secs.	Development completed. Mins.	Colours.
Series 1.						
1	1	X	60	90	10	Blue grey, weak, slightly flat.
2	1	X	65	90	8	Warm gray, more luminous than No. 1.
3	1	X	70	75	6½	Warm grey, good density.
4	1	X	75	50	5½	Colder and weaker than 3.
5	1	X	80	35	4	Warm grey, warmer than 3, best slide in Series 1.
Series 2.						
1	½	X	70	60	7½	Yellowish grey.
2	½	X	70	60	7½	Cold grey.
3	1	X	70	60	6½	Colder and weaker than 2.
4	2	X	70	60	6½	Greenish blue, good depth, best slide in Series 2.
5	4	X	70	60	6	Violet grey, slightly flat and muddy.
Series 3.						
1	1	T	70	20	11½	Purple brown, good depth, shadows rather heavy.
2	1	W	70	45	4½	Greenish blue (cold), good depth.
3	1	X	70	60	6½	Warm blue black, slightly heavy.
4	1	Y	70	75	7	Brownish violet.
5	1	Z	70	75	8	Warm black, best slide in Series 3.
Series 4.						
1	1	T	50	150	25	Warm brown, slightly uneven density.
2	1	W	60	90	8	Warm black, heavy shadows.
3	1	X	70	60	6½	Grey, weak density, as 3, Series 2.
4	1	Y	80	45	5½	Colder and weaker than 3.
5	1	Z	90	30	3	Brown to chocolate, best slide in Series 4.
Series 5.						
1	½	X	80	30	3½	Warm grey, very luminous.
2	½	X	75	75	7	Warm grey, warmer than 1, yellowish high light.
3	1	X	70	75	7½	Cold grey.
4	1½	X	65	105	9	Cold greenish grey.
5	2	X	60	135	11	Greenish grey, deeper than 4, best slide in Series 5.
Series 6.						
1	½	T	70	35	4	Warm chocolate brown, fine luminous slide, best in set.
2	½	W	70	50	4½	Cold grey, washed out.
3	1	X	70	60	6	Blue grey, darker than 2.
4	2	Y	70	70	7	Purple brown, heavy shadows slightly clogged.
5	4	Z	70	90	10	Warm purple, luminous.

Exhibit No. 687 represents a set of 10 slides illustrating the influence of the proportion of thiocarbamide in the developer upon the colour of lantern slides.

These slides are to be considered as a pendant to Set No. 686, and again the third slide of each series represents the normal as explained above.

Thiocarbamide is a solvent of the silver halide of the plate and, further, has a powerful retarding influence on development. The practical effect would appear to be that where the proportion of Solution C exceeds the normal, the increased solvent action operating during the more prolonged development produces a flat over-exposed effect, and it is difficult to secure full density. On the other hand, with a proportion of Solution C below normal, the more rapid development secures full density before the solvent action has had time to operate fully. The

application suggested is that, with a thin negative, the proportion of Solution C should be decreased, and with a contrasty negative be slightly increased to secure the best results.

Series 7 shows effect of varying both the exposure and proportion of Solution C. Series 7A, of varying proportion of Solution C only, the other factors remaining constant.

The deduction from these is that thiocarbamide, although retarding development, is not a restrainer in the photographic sense, and does not tend to increase contrast.

DETAILS OF THE EXPERIMENTS.

Slide.	Exposure.	Developer.			Temp. Deg.	First appearance of the image. Secs.	Development complete. Mins.	Colours.
Series 7. No.		Sol. A. Parts.	Sol. B. Parts.	Sol. C. Part.				
1	¼	6	1½	½	70	30	4	Warm brown, fine and luminous.
2	½	6	1½	⅓	70	40	4	Yellowish brown.
3	1	6	1½	½	70	60	6	Cold purple brown.
4	2	6	1½	⅔	70	80	7½	Purple grey, uneven density.
5	4	6	2½	⅚	70	120	13	Yellowish purple, weak and washed out.
Series 7A.								
1	1	6	1½	⅙	70	20	2	Warm chocolate, best slide in this set.
2	1	6	1½	⅓	70	25	2½	Chocolate, slightly colder than 1.
3	1	6	1½	½	70	45	4½	Purplish green, uneven density, flat.
4	1	6	1½	⅔	70	65	6½	Warm purple, uneven density.
5	1	6	1½	⅚	70	85	8½	Weak yellowish brown, uneven density.

Attention is directed to No. 5 of Series 7. It was obvious when developing No. 4 of that series that the exposure given to No 5 would be far too much for the developer being used, and the result would be useless. The proportion of Solution B was, therefore, increased to 2½ parts with a view to counteract the excessive exposure. This, by prolonging development, probably did more harm than good.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, OCTOBER 2.

Bradford Phot. Soc. Social and Musical Evening.
Southampton C.C. "In Pictureland With a Camera." Rev. W. Hogan.

TUESDAY, OCTOBER 3.

Exeter Camera Club. Presidential address delivered by Dr. C. Beauchamp-Hall, F.R.C.S.
Hackney Phot. Soc. "In and Around Quaint Holland." E. T. Coombes.
Manchester Amateur Phot. Soc. Exhibition of Prints, by Fred Judge.

THURSDAY, OCTOBER 5.

Hammersmith Hampshire House Phot. Soc. "Chinese and Indian Hard Stone Carvings." Cecil Thomas.
Rochdale Amateur Phot. Soc. Annual General Meeting.
The Royal Photographic Society. "The Use and Misuse of Short Focus Lenses. R. H. Lawton, F.R.P.S.

SATURDAY, OCTOBER 7.

Edge Hill Camera Club. Outing to Ormskirk and District.

CROYDON CAMERA CLUB.

The informal session, rapidly drawing to a close, once again indicated its versatility last week, when Mr. A. H. Tarry demonstrated "Casting Flowers in Metal," one of the most wonderful working expositions ever given in the club-rooms.

A loganberry leaf was taken, and within an hour or so a perfect cast in aluminium was produced, faithful even to minute hairs.

Briefly, the procedure is as follows:—The flower, leaf, butterfly, or other natural object is coated with shellac solution, and then painted round with an investment material capable of withstanding intense heat. The mould is then heated to carbonise the encased object, debris being removed by washing with mercury. Finally, the metal is melted by blowpipe or oxy-hydrogen jet, and forced into the mould under heavy pressure

Exquisite specimens, many seemingly impossible to cast, were passed round, including some in gold, which, it may proudly be recorded, were all returned. In reply to a question, the lecturer said it would be quite feasible to cast a spider's web, provided the strands were strong enough to withstand the preliminary treatment. A suggestion by a member that the chairman, Mr. Rose, should be cast in metal as a permanent adornment for the club-rooms was modestly negatived by this flower of the flock.

A most hearty vote of thanks was accorded Mr. Tarry, who, in replying, observed that a number of hospitable friends had pressed him to take a drink, but nothing had materialised. Luckily, the rational hour permitted this serious omission to be rectified.

Commercial & Legal Intelligence.

NEW COMPANIES.

PARADE DRUG STORES, LTD.—This private company was registered on September 16 with a capital of £1,000 in £1 shares. Objects: To carry on the business of dealers in photographic goods and materials, opticians, etc. The first directors are: W. A. King, 58, Cazenove Road, N.16, tobacconist; E. J. Reedman, 9, Green Lanes, N.16, pharmaceutical chemist (managing director). Qualification, one share. Remuneration, £500 divided between them. Registered office: 9, Green Lanes, Stoke Newington, N.16.

NATIONAL TRADE MONOTYPERS, LTD.—This private company was registered on September 16, with a capital of £2,500 in £1 shares. Objects: To adopt an agreement with J. W. Lawson, and to carry on the business of printers, stationers, mechanical typesetters, lithographers, type founders, stereotypers, electrotypers, photographic printers, etc. The first directors are: W. Tomlin, 15, Waterloo Road, Barnsley, printers' manager; J. W. Lawson, 14, Russell Street, York, printers' manager. Qualification, £100 sharse. Secretary, J. W. Lawson. Registered office: 8-10, Wyre Street, Ardwick, Manchester.

GRAYS PUBLISHING CO., LTD.—This private company was registered on September 14 with a capital of £12,000 in £1 shares (6,000 preference). Objects: To take over the business of printers, publishers, photographers, producers and vendors of picture postcards, guide books and letter cards carried on at 13, Gray's Inn Road, W.C., as "Grays Publishing Co." The subscribers (each with one share) are: Mrs. A. M. Barley, Leutchine, Burlington Road, Swanage; Pindo Ajelli, 13, Gray's Inn Road, W.C.1, fine art publisher. The subscribers are to appoint the first directors. Qualification: £100. Remuneration as fixed by the company.

YEVONDE, LTD.—This private company was registered on September 12, with a capital of £2,000 in £1 shares. Objects: To take over from F. H. Swoffer, or his trustee, the business of a photographer, carried on at 10, St. Ann's Square, Manchester, and to acquire from Yevonde Middleton, of Victoria Street, Westminster, the non-exclusive use of the name "Yevonde" used by her in connection with her photographic business, with a view of carrying on the businesses so to be acquired as "Yevonde, Ltd.," to adopt agreements (1) with H. Sharp and the said F. H. Swoffer and (2) with the said Yevonde Middleton. The first directors are: Muriel Oliver, The Waterhouse, Bollington (chairman); Yevonde Middleton, Victoria Street, Westminster. Remuneration of Muriel Oliver, £250 for first year and £300 for each subsequent year; of the said Yevonde Middleton, £150 per annum. Qualification of Muriel Oliver as chairman, 500 shares; of Yevonde Middleton, 250 shares.

THE CLUB PHOTOGRAPHER.—The October issue of the "Club Photographer" contains articles by members of the Preston Camera Club, amongst them one on the "Paget Colour Process" and another on "Nature Photography."

News and Notes.

BRIFCO, LIMITED.—The registered office of this company is now at Trafalgar House, 11, Waterloo Place, London, S.W.1, to which new address all communications relating to the company's business should be sent. The company's new telephone number is Regent 3227.

COLLOID CHEMISTRY.—The "Fourth Report on Colloid Chemistry," arranged by the Department of Scientific and Industrial Research, has just been published. It deals in a very exhaustive manner with the various applications of colloid chemistry to manufacturing processes, and will be of great value to works chemists. Copies of the Report may be obtained from H.M. Stationery Office, Imperial House, Kingsway, W.C.2, or 37, Peter Street, Manchester, price 5s. 6d. net.

LAFAYETTE, LTD.—The staff of this well-known establishment, to the number of fifty persons, held their annual excursion to Westcliff-on-Sea on Saturday, September 23. After exploring the delights of the town, dinner was served at the "Acorn" under the chairmanship of Mr. Lundie, supported by Misses Rearden and White. A vote of thanks was carried with acclamation to Mr. Jas. Lander for granting the holiday and financially helping towards its success. Bathing at Canvey Island and visits to the Kursaal added to the pleasure of the outing, and a concert and dance closed a successful day.

METRIC EQUIVALENT AND MENSURATION SCALES.—A series of sixteen tables produced by photographic methods and printed in pocket folder form is being supplied by Mr. A. E. Bawtree. This comprises a handy and convenient method of calculation which should be of use to photographers, scientists and students. The scales are plainly printed, and include weights, measures, temperature tables, etc. The process by which these scales are prepared is illustrated at the R.P.S. Exhibition in frame No. 268, where details of the process are given. The price of the folder is 1s., post free, from Mr. A. E. Bawtree, 7, Manor Park Road, Sutton, Surrey.

PHOTOGRAPHY IN THE HOME is the title of a very instructive little booklet now being issued by Messrs. W. Butcher and Sons, Ltd., Camera House, Farringdon Avenue, E.C.4. Twenty pages of information and suggestions for winter camera work, by Harold J. Grainger, precede a catalogue of enlargers, flashlamps, mounts, etc., and make the book of especial value to the camera worker during the winter months. The booklet is supplied to dealers at a low price, viz., 100 for 5s., 250 for 7s. 6d., 500 for 12s. 6d., and 1,000 for 20s., these prices including the imprinting of the dealer's name and address and the supply of a useful window slip.

R.P.S. EXHIBITION.—The October issue of the "Photographic Journal," the official organ of the Royal Photographic Society, will be a special exhibition number, and will contain a large number of reproductions of photographs included in the Society's sixty-seventh exhibition, now open at 35, Russell Square. In addition, the various sections of the exhibition will be reviewed by well-known authorities, so that the issue will form an interesting and instructive record of the exhibition. It is to appear to-day, September 29, and copies may be obtained from the Secretary, Royal Photographic Society, 35, Russell Square, W.C.1, price 1s. 8d. each, postage included.

NORTH YORKSHIRE AND SOUTH DURHAM PROFESSIONAL PHOTOGRAPHERS' SOCIETY.—The fourth meeting was held on Tuesday, the 19th inst., in the studio of Messrs. A. E. Ball & Son, Stockton-on-Tees, when the members were given a very interesting demonstration by Mr. Wesson, of Wellington & Ward, Ltd., of Wellington B.B. paper. The able way in which the demonstrator dealt with his subject made the lecture all the more interesting, and the development and toning of the various prints which he made were followed with keen interest by all present. At the close of the lecture light refreshments were provided, and very hearty votes of thanks were passed to Mr. Wesson, and also to Messrs. Wellington & Ward.

COLOUR CINEMATOGRAPHY.—The "Times" New York correspondent reports that a process of colour cinematography, the result of seven years' work by an American scientist, Mr. Daniel Comstock, is announced by Mr. William Travers Jerome, the New York lawyer, who has organised a company of New York business men and cinema producers to exploit the discovery. The great virtue claimed for his invention by Mr. Comstock, apart from its perfection in colour rendering, is its cheapness. The film is photographed in the ordinary manner, but with a special camera. After development, it is run through several chemical baths, which produce the required tints. The cost of colouring is stated to be negligible. Mr. Comstock is, of course, well known as a patentee of processes and apparatus for colour photography.

PROFESSIONAL PHOTOGRAPHS IN GLASGOW.—Special attention may be directed to the exhibition of professional photographic portraiture, which has been arranged by the Glasgow and West of Scotland Society of Professional Photographers, and will be opened on Monday, October 2, at the McLellan Galleries, Glasgow, by the Lord Provost. We believe this is the first occasion on which an exhibition solely of professional photographs has been held in Scotland under auspices which will attract a large attendance on the part of the public. Admission to the exhibition is free, and during the period of the exhibition lectures will be given by Mr. C. P. Crowther and others. We wish our Scottish friends well in this piece of enterprise undertaken with the object of enlisting the interest of the public in the commercial capital of their country.

BUTCHER'S WINTER CATALOGUE.—This interesting booklet has reached us from Messrs. W. Butcher and Sons, Ltd., Camera House, Farringdon Avenue, E.C.4. It contains particulars of many lines, particularly suitable to the winter trade. Amongst these we may mention the "Club" and the "Home" lanterns, both of which are built on unique lines. The "Dualite" enlargers for use without condensers are novel in design and practical in making. The "Empire" series of home cinematographs will appeal to many amateur film makers during the winter months, and for these workers, film printers and developing frames are also supplied. The Christmas trade is provided for in passe-partout calendars and greeting cards, and also the well-known series of Primus engineering sets. As Messrs. Butcher's say, this booklet is truly a "winter encyclopedia" and we recommend our dealer friends to obtain a copy.

AWARDS AT GLASGOW.—In the Photographic Section of the Housing and Health Exhibition which opens in Kelvin Hall, Glasgow, on October 2, the trophy offered for the best print in the exhibition was awarded to John Baird. The following awards have also been made. Class 1: 1st, John Baird; 2nd, Louis J. Steele; 3rd, A. T. Edgeley. Class 2: 1st, Mesdames Morter; 2nd, G. Hill; 3rd, S. Langfier. Class 3: 1st, Dan Dunlop; 2nd, Mesdames Morter; 3rd, H. G. Ballance. Class 4: 1st, John Williamson; 2nd, A. L. Hitchin; 3rd, H. Hardaker. Class 5a: 1st, Robert Ure; 2nd, Chas. J. Bryden. In the amateur and juvenile section the following awards were made:—Class 1: 1st, A. B. Ferguson; 2nd, Miss M. E. Watts; 3rd, Wm. Lindsay. Class 2: 1st, J. T. Reid; 2nd, Evelyn S. Morrison; 3rd, Miss G. Thomson. Class 3: 1st, Miss M. F. Daniel; 2nd, A. B. Ferguson; 3rd, Jas. W. D. Sandison. Class 4: 1st, A. D. Hitchin; 2nd, Robt. Dunlop; 3rd, Miss Peggy Sandilands. Lantern slides: 1st, Herbert Felton; 2nd, Ranald Rigby; 3rd, Dan Dunlop; 4th, Ernest Tinker.

CLIMATE AND PHOTOGRAPHY.—A paper by Mr. H. G. Cornthwaite on this subject appears in the "U.S. Monthly Weather Review" for March. According to an abridgment of it in "Nature," it is mentioned that during a heavy rainfall the light is photographically stronger than in densely cloudy weather without rain, due to the light reflected from the falling raindrops. Tropical daylight is asserted to be about twice as strong photographically as summer daylight in latitude 40 deg., and about four times as bright as winter daylight at this latitude. Chemical activity in developing and fixing processes is greatly increased with high temperatures, and correspondingly retarded with low temperatures. Photographic films and prints may be subjected either to high temperatures or high humidity without excessive deterioration, but not to both in combination. Both prints and films are said to deteriorate rapidly in the moist tropics, but those developed and fixed under tropical conditions have a greater permanence in the tropics than those developed and printed in the temperate zone and subsequently taken to the tropics.

CROYDON CAMERA CLUB.—For good fellowship, coupled with wit and learning, the Croydon Camera Club stands perhaps alone. The amusing, yet interesting, criticism which is levelled at the lecturer, to say nothing of the members themselves, makes it a real pleasure to attend the weekly meetings. One is sure that there will not be a dull moment during the evening, as the club critics are certain to object to the lecturer's point of view, and a witty argument between the members ensues. The session commences on Wednesday, October 4, at eight o'clock, when Mr.

R. J. Rose will show "Some Photographic Odds and Ends." The programme for the session is now available, and may be obtained from the Hon. Secretary, J. M. Sellors, 50, Russell Hill, Purley. Judging by the list of lecturers and their subjects this should be an interesting and instructive session, and the members should have plenty of opportunity to exercise their powers of criticism to the full. Amongst the lectures are many which are calculated to interest the beginner, and this instruction, together with the friendly and jovial spirit of the club, should do much to help him in his work.

PHOTOGRAPHIC INSTRUCTION IN MANCHESTER.—The prospectus of the printing and photographic department of the Manchester Municipal College of Technology is now available for intending students. The photographic section provides evening and all-day instruction in pure photography and the photo-mechanical processes. A complete daylight and artificial light studio is provided for portraiture and general technical negative making, together with an efficient dark-room, printing room, and a well-equipped laboratory. The process studio contains four cameras, one 12 x 10 and three 15 x 12 sizes. Three dark-rooms are provided in this department, enabling wet collodion and dry plate negative making to be accomplished. There is also an etching room, including two etching machines and a complete block finishing room. Instruction is also given in retouching and finishing photographic prints, by expert instructors. Mr. Charles W. Gamble, O.B.E., M.Sc.Tech., is the Director of the photographic departments, and application should be made to him by intending students for particulars of the classes most suitable to their requirements. These classes of instruction should be of great value to persons in the neighbourhood of Manchester who propose to enter one or other of the branches of photography as a means of livelihood. The school session commences on October 2.

THE EASTMAN THEATRE AND SCHOOL OF MUSIC.—An excellently printed four-page art gravure supplement to the "Democrat and Chronicle" of Rochester, N.Y., for September 10, 1922, includes illustrations and particulars of the Eastman Theatre and School of Music. This theatre and school were presented to the people of Rochester, N.Y., by Mr. Geo. Eastman, for the purpose of developing musical talent and appreciation, and were opened to the public on September 4. Mr. Eastman's original gift amounted to 3,520,000 dollars, to which was added, a few months later, 1,000,000 dollars for building and equipment. A smaller hall, which is an adjunct of the School of Music, was designed essentially for recital purposes, but has a complete motion-picture equipment. The organ in this hall represents an investment of 90,000 dollars. The large theatre, which is described as the most beautiful in the world, abounds in architectural beauty and wealth of art treasures, and its equipment and accommodation are said to be surpassed. The auditorium, which has a seating capacity of 3,358 persons, is completely open, no posts or girders interfering with the view of the stage. Music for motion pictures is provided by a full symphony orchestra and an eight-division organ with more than 10,000 pipes, said to be the most complete ever installed in a theatre. Mr. Eastman's interest in music and genius in organisation appear to have found the happiest conjunction in the planning of this notable addition to the social life of Rochester.

PHOTOGRAPHIC INSTRUCTION.—Evening classes of instruction in pure photography have been a special feature of the Battersea Polytechnic, Battersea Park Road, S.W., for a number of years, and have been of great assistance to students of the art. The photographic department of the Polytechnic contains a fully-equipped studio and commodious dark room, both fitted for electric illumination, besides the necessary apparatus for the subjects in which instruction is given. An elementary class on Tuesday evenings, and an advanced class on Thursday evenings, are held, the latter preparing students for the City and Guilds final examination in photography. Mr. E. Senior, the instructor, has a wide knowledge of his subject, and is a very capable lecturer. The fees for these classes, comprising 2½ hours' instruction in theory and practice, is 20s. per session for both the elementary and advanced courses. A special course in enlarging is also provided on Tuesday evenings from 7.30 to 9.30. The fee for this instruction, extending over twelve evenings, is 10s. Mr. Senior is also delivering a course of about twenty-five lectures on photography at the South-Western Polytechnic, Manresa Road, Chelsea, S.W.3, at 7.30 p.m. One hour's lecture is given, followed by practical work. The fees for the course of lectures and practical work is 20s. per session. Practical demonstrations in photo-micrography will also be given at this Institute, commencing May 7, 1923. The fee, covering eight demonstrations, is 5s.

CO-OPERATIVE ADVERTISING.

To the Editors.

Gentlemen,—I think I must have been the last photographer to register as attending the Congress, since you give the number attending as 291, and my badge number was 292. That I was unable to attend until the Friday was undoubtedly my loss, as it was regret, because of the very attractive programme arranged.

Particularly I regret missing Capt. F. H. Wright's address on Co-operative Advertising on the Wednesday afternoon, which from your report appears to have been very informative and instructive. Unfortunately the address on the same subject on the Friday by Mr. Hopton Hadley was somewhat spoiled by being hurried, through the late start owing to the general annual meeting of the P.P.A. encroaching on the time allotted to Mr. Hadley, and also by the fact that the arrangements for the Congress dinner made it necessary for the chairman to hurry the proceedings, leaving but little time for discussion.

This subject is one of extreme importance to the whole body of professional photographers, and whilst it is fitting that the proposition be left *pro tem.* for the Council to discuss, it is quite imperative that the matter be not pigeon-holed indefinitely, but that ways and means are found of starting the scheme early in the New Year.

For such a great length of time photographers, as a body or individually, have relied on indirect methods of advertising, in many cases bolstered up by broadcast invitation sittings, so that the public have, as a rule, a very poor opinion of photographers from the business point of view, if not from the social. The objection to direct advertising, from the viewpoint of the better class studio, has been that it is undignified and unprofessional; from the standpoint of the cheaper studios, that it probably does not pay. Both views are wrong, because (1) there is nothing undignified in letting the public know what one has to sell, in a decent, straightforward manner; (2) the professional photographer is not "up against" a union, such as the Law Society or the Medical Association, prohibiting direct advertisement. After all, the photographer does sell *things* (photographs, products of his and his staff's services), and not merely services or advice, like the professions mentioned. (3) Since he sells things, why should it not pay the photographer to advertise? It is a proved fact that it pays every other form of business to advertise its goods.

Having arrived at the conclusion that advertising pays, undoubtedly more could be done in educating the public to be photographed oftener by some co-operative scheme, because it is the only way that large sums of money could be raised to tackle the job in any efficient manner. It requires handling by experts and putting out to the right kind of papers, having regard to the variations in the status of different photographic studios and their clientele. I quite agreed with Capt. F. H. Wright that £12,500 is none too much to carry out the campaign. Given skilful handling, with efficient advertisements bringing in results, I think double this amount might be raised the second year, for the price of a new 14 x 8 ft. background from each of the 8,000 photographers calculated as likely to subscribe would bring in about £30,000. Very few photographers would hold out if results accrue.

My question to Mr. Hadley is not reported quite correctly. It was, "Would the methods suggested by Mr. Hadley raise a sufficient sum?" and not, as you say, "Was it really possible to raise sufficient?" My point is that it should be quite possible, but I do not think the amount stated by Mr. Hadley as required for a start would be sufficient.

Another point in the education of the public to want photographs more frequently is, that photographers as a body should devise some ready method by which the public can keep and protect a collection of photographs—something that will take the place of the old family album. It is quite impossible for the public to frame more than a small proportion of the photographs

they receive, if only from lack of space in which to place them. The consequence is that they are soon damaged and put out of sight. If a ready method could be found whereby anyone could keep a collection of portraits in a compact form, ready to look through and show to friends, much more interest would be taken in them, and hence there would be more demand for the photographer's efforts. I enclose an advertisement of an attempt on my own part, but one man can do little, it requires the united effort.

It is an undoubted fact that, despite high taxation and the general high cost of living, the public still have some money to spend, and if photographers as a body are content to sit still and see all this spare cash go to such things as golf, tennis, the cinema, chocolates, etc., they must only blame themselves if the public has very little left for portraiture. It is up to photographers to combine and make the public want portrait photographs oftener by co-operative advertising. Ultimately it would more than pay them to do so.—Yours truly,

JOHN MILLS.

10, Saint Giles' Street, Northampton.
September 23.

THE BEGINNER IN PHOTOGRAPHIC SOCIETIES.

To the Editors.

Gentlemen,—Your correspondent A. V. W. displays a degree of selfishness which, from a somewhat extended acquaintance with society members, I am glad to think must be very rare.

Before beginners can be excluded it must be decided what a beginner is. An experienced professional portraitist is a beginner when he first essays a landscape, and even an experienced amateur who claims to be an all-round expert is, as I know, capable of asking very funny questions regarding such a subject, for example, as stereoscopic photography.

I claim that the beginners, with their overflowing energy and zeal, are the backbone of the societies, both financially and otherwise.

There is no better way of ascertaining the limit of one's own knowledge than by trying to teach others, and many old hands would at times find themselves in difficulties when asked to explain the reason for some of their operations.

My old society (when I lived in London) at Bowes Park held special beginners' evenings, at which demonstrations were given by the more experienced members, and beginners encouraged to work under their supervision. The successes gained by this society at the White City, Crystal Palace, and other similar exhibitions is, to my mind, sufficient evidence that the encouragement of beginners is justified.—Yours faithfully,

H. A. MILES,
Past-President Bowes Park and District Photographic Society.

180, Shaftesbury Avenue, Thorpe Bay.
September 15.

[Letters expressing the same views as those of Mr. Miles have reached us from Mr. R. S. Galloway and Mr. J. Ainger Hall respectively of the Edinburgh and Hammersmith Photographic Societies.]

FLASHLIGHT FOR PORTRAITS OF CHILDREN.

To the Editors.

Gentlemen,—Noting that you advise a correspondent, in to-day's issue, that you "do not think flashlight can be recommended for the portraiture of children," may I venture an attempt at conversion of that opinion?

Flashlight is, to my mind, of greater value in that particular work than, probably, in any other branch. For one thing, the actual duration of exposure is shorter than anything except shutter work in sunlight. So that when a child has been watched or coaxed and the desired expression appears, it can be caught with far less chance of movement than any ordinary studio conditions permit. There ought to be no doubt remaining nowadays that flashlight can easily give as well lit pictures as any other illuminant.

The only other matter on which a question might arise is the suddenness of the flash. Many people have asked me if it does not frighten children. To that I can only reply that in all my experience only one child has shown any alarm, and he was an extraordinarily nervous child, born in specially distressing circumstances. Even in his case it was more the camera being pointed at him than the flash that aroused his antipathy, and I am enclosing for your inspection a print from each of the two exposures taken of that unusually difficult child as proof that flashlight for babies is not only suitable, but that it is the best method of all.—Yours faithfully,

D. CHARLES.

50, Webb's Road, Clapham Junction, S.W.11.
September 22.

[The portraits are excellent in expression and lighting.—EDS., "B. J."]

TECHNIQUE AND THE D. AND P. SLUMP.

To the Editors.

Gentlemen,—*A propos* the article under the above heading in a recent issue, I venture to offer the view of an amateur having a wide and very long photographic experience. I may say that I am very frequently called on to admire "snaps" by friends and relations: these efforts being, in nearly every case, of the D. and P. order. Almost without exception the results displayed horrify me, and cause me to be ashamed of my hobby. I give full blame to the happy "snapper"; but in the majority of cases the "finisher" appears to have "done his worst," and especially in respect to the printing from negatives. Few of these machine-made prints do justice to the better negatives, while they effectually "finish" (!) the poor ones. In this respect I consider the D. and P. man is his own "worst enemy." So far as personal experience goes, I have not, until this summer, had occasion to test the skill of the D and P. "service." However, this became necessary during a holiday tour, in order to test the speed of two recently introduced British films. With a wish to compare results I placed two films with shops of widely differing pretentions, the one, a much window-dressed firm, the other a small chemist's shop in a by-way. Briefly, the results were these: The pretentious firm, which announced "Best Possible Results," all but ruined the film. The timing of development was bad, and the drying so obviously careless as to leave the back of the film badly marked. Pinholes were also numerous. In the case of the "small chemist" the film was developed correctly and with the "best possible results" claimed by the pretentious rival!

This experience goes to endorse the view of "Thermit" that there is far too much slipshod work among those in the D. and P. line of business. In regard to printing, I think it might be said that thousands, possibly millions, of snap-shotters are educated, photographically, on bad gaslight prints, and have never seen first-class work on bromide paper.—Yours faithfully,

LYULPH LUMLEY.

66, Sunny Gardens, Hendon, N.W.4.

POTASS. FERROCYANIDE IN THE DEVELOPER.

To the Editors.

Gentlemen,—On page 544 of the "B. J.," dated September 8, there is a brief reference in one of your replies to the use of potass. ferrocyanide in the developer, you stating—and rightly so—that the idea of using ferrocyanide originated in America some years ago.

About the middle of the year 1884 a New York photographic expert discovered that ferrocyanide was a good thing to use as a constituent of a pyro-potash developer. The idea was noised abroad, although efforts were made, I believe, to keep the discovery secret. At any rate, the use of ferrocyanide became so common that in March, 1885, a standard developer containing the salt was adopted by the Society of Amateur Photographers of New York for some important work then in hand.

The developing formula decided upon was as follows:—

Pyrogallic acid	2 grs.
Soda carbonate	5½ ,,
Soda sulphite	11 ,,
Potass. carbonate	5½ ,,
Potass. ferrocyanide	5½ ,,
Water	1 oz.

The work for which this formula was employed was that of testing (by a special committee) the qualities of twenty-two different brands of dry plates by twenty different makers—eighteen American, one English, and one Belgian.

The plates were also tested with the formula recommended by the makers of the plates. The ferrocyanide formula gave the greatest satisfaction, the workers claiming that when ferrocyanide was used

less pyro was required. Dealing with this particular point, the official report issued by the Society said: "In one case 2 grs. of pyro in our standard developer gave as good results as 5 grs. in the makers. The developer works well with every plate we have tested, though it requires a bromide on some of the extra sensitive plates to prevent fogging."

As many as 254 tests in all were made, and the developer had a good run, but for some reason or other the formula did not live many years, even though efforts were made to embody ferrocyanide in other and more popular formulæ.—Yours faithfully,

W. W. N.

ASSISTANTS AND THE CONGRESS.

To the Editors.

Gentlemen,—I was specially favoured to attend some of the lectures held at the recent P.P.A. Congress, and feel I must make an attempt to express my appreciation, and thanks to all concerned. There are two evenings that stand out as unique to me.

The first is Mr. Pirie Macdonald's lecture. Words fail me to express my gratitude and feeling to such a wonderful man and photographer. If every assistant could have heard him, I am convinced it would have been the finest lesson any photographer could have heard. I had the good fortune to meet him the day before he left, and he promised on his next visit to this country to give assistants an evening. Now we come to the Assistants evening (Thursday). In all my twenty-three years' experience in photography this has been the first assistants meeting. I sincerely hope this is the beginning of many more. I also feel it is absolutely essential for us to have an assistants' association for many reasons, viz., to improve the condition and quality of work and sociability amongst assistants.

Lectures should be given not only on photography, but commerce, science, literature, astronomy, and many other subjects too numerous to mention. Include the trade assistants; they will be a great help to us all, especially the demonstrators, as there are many of us who do not know the way the material is manufactured, I am sure the P.P.A. Council will find the right man to lecture to us.

An exhibition should be held for the assistants only, showing the branch in which they specialise, viz., operating, developing, retouching, printing, finishing, mounting, and judged only on the one subject or branch.

We were told at the meeting that it is necessary for the operator to study the sitter; it is equally important that the master photographer must study the assistant in every branch of the finished result; and the assistant, the master. If conviviality was more in prominence in the photographic workroom the average assistant would be happier.

It must be remembered we all have our livelihood to get, and cannot live on sentiment, but until photography is improved we cannot expect to obtain better conditions and wages, which I hope will soon come.—I remain,

Yours faithfully,

FRANK V. SYMMONS.

43, Dover Street, W.1.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

S. L.—The type of print you have seen was probably produced either upon Kodak "Transferotype," which is a stripping paper and allows the picture to be transferred to any type of paper base, including Japanese vellum, or "Kerotype" transfer paper, made by Criterion, Ltd., Stechford, Birmingham.

C. W.—A burnished mirror reflects approximately 80 per cent. of light as observed by the eye. In the case of using two mirrors, 80 per cent. of the light reflected by the first would be reflected by the second. Thus 64 per cent. of the original light would be available. In practice, however, it is found that a larger proportion of light than these figures show is really reflected.

W. S.—Your background should first have a good coating of thin starch paste rubbed well into the material. When this is dry, any of the good makes of washable distemper may be applied. We have treated this matter rather fully in the "B. J." of the following dates: May 20, 1921, p. 300, and January 27, 1922, p. 47. Copies of these issues may be obtained from our publishers, price 9d. each, post free.

A. O.—The approximate electric power required by you is as under:

(1) Printing box for gaslight and bromide, 80-100 c.p.
(2) Enlarging, 400 c.p.
(3) Studio, two or three lamps, totalling 6,000 c.p.

Using half-watt lamps, this would need a supply of about 3,250 watts. If you divide this figure by the voltage you have available you will obtain the amperage necessary to light all your lamps at once.

A. C.—Your difficulty in firing flash powder by a high-tension spark is that the metallic powder proves a conductor for the current, and consequently the effect of the spark is lost. If you have electricity available it is best to fire the powder by means of a piece of fine fuse wire: when the current is switched on the fuse burns out, thus igniting the powder. It is possible to use the lamp you mention at the distance you require, a special long wire release being provided for the purpose.

C. R.—We have never seen any larger ferrotype plates than 14 x 10. As they are, we believe, all made in America, it would be difficult to get special sizes. If the number you quote is correct, your Dallmeyer lens is the stickyback size. The fact that it has Waterhouse diaphragms and is not marked "Patent" would indicate that it was a kind called many years ago the "New Stereoscopic Lens," but so far as we know none of these would bear so high a number. In any case, it would be a Petzval type portrait lens. We cannot fix a selling value.

DAVID C. PRICE.—(1) We do not know of a material which is perfectly opaque (free from holes) in a single thickness, and, at the same time, is a reasonable price. For blocking out the whole of the light absolutely, two blinds are necessary whatever the material. We have used the material sold by any large draper as "silesia" satisfactorily, although at the present time it is rather expensive. (2) A photographer has no right to make any use of prints from a customer's negatives without the customer's permission, even though the prints have not been paid for owing to any cause. Under copyright law the owner of the negative in such circumstances as you describe has the sole right to make and exhibit prints from the negatives.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3257. Vol. LXIX. FRIDAY, OCTOBER 6, 1922. Price Fourpence.

Contents.

SUMMARY.

The series of reviews of the exhibition of the Royal Photographic Society is brought to an end by a notice of the natural history section written by Mr. Harold Hurden, who finds much to commend from both the technical and pictorial standpoints. (P. 603.)

Judged by the prints at the exhibition of the Royal Photographic Society, bromide paper out-distances all the other processes in the production of prints (many of them, portraits) having a claim to artistic quality. (P. 602.)

We greatly regret to record the death in his 81st year of Major-General J. Waterhouse, for many years assistant surveyor-general in charge of photographic operations of the Indian Survey Office, and the author of many notable contributions to photographic and photo-mechanical processes. (P. 604.)

It is announced that next year's Photographic Fair will be held at the Holland Park Hall, close to Shepherd's Bush station. The Fair is to remain open from Thursday, March 15, to Saturday, March 24. (P. 601.)

The vagaries of our present system of protection of industries by means of a duty on certain classes of imported goods are exhibited by the successive official changes of front which have been made in reference to gallic acid. (Pp. 601 and 605.)

In a leading article we have some hints to give on the choice of focal length of lens in reference to the size of the plate. It cannot too often be emphasised that the "drawing" of the subject is dependent on the view point, and that the scale of reproduction is determined by the focal length of the lens. (P. 602.)

An American paper company, so it would seem, has put forward identically the same suggestion for a series of standard sizes which Mr. Alfred Watkins published in our pages just about two years ago. (P. 602.)

Many hints on paints and varnishes were given by Mr. Vivian Jobling at the Croydon Camera Club. (P. 611.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

Mr. Charles Raleigh concludes his reminiscences of the many technical difficulties in the working upon the commercial scale of the Kinemacolor process of colour cinematography. (P. 37.)

M. Eugène Muller has recently recorded his observations on the occurrence of a prevailing blueness in Autochrome transparencies. By use of a somewhat deeper compensating light-filter he has been able to obtain Autochrome transparencies of entirely satisfactory colour rendering. (P. 38.)

An invention of a triple-film plate for the simultaneous making at one exposure in an ordinary camera of the set of colour-sensation negatives is that of E. A. Lage, and appears to be the partial basis of the process of colour photography recently shown for the first time at the trade exhibition of the P.P.A. Congress. (P. 40.)

Still another variant of the numerous methods of cinematography in colours is described in a recent patent specification. (P. 39.)

EX CATHEDRA.

The Photographic Fair, 1923. An announcement of great interest respecting the Photographic Fair, which for a number of years past has been held at the Horticultural Hall, Westminster, is that its organiser, Mr. Arthur C. Brookes, has been able to secure the Holland Park Hall for next year's Fair, to be held from Thursday, March 15, to Saturday, March 24. Although the Horticultural Hall is an excellent building, its size has not been sufficient for the accommodation of a trade exhibition upon a scale in correspondence with the magnitude and importance of the photographic industry. The Holland Park Hall will provide about three times the floor space, in addition to that in galleries which will be devoted to a variety of attractions. While the new venue of the Fair is somewhat further from the centre of London, it is probably more accessible than the Horticultural Hall, since it is a stone's throw from the Shepherd's Bush station on the Central London railway, and also stands on a main bus route. Also, the period of the Fair can be made slightly longer, and the date made to coincide with the opening of the photographic season, since Easter Monday next year falls on April 2, just over a week after the closing of the Fair.

* * *

See-Saw Protection. If anything were required to demonstrate the beautiful uncertainties of the system of protection which is embodied in the Safeguarding of Industries Act, it is the proceedings of last week in reference to gallic acid, which are reported on another page. One has only to review the successive stages in the treatment of this substance according to the Act in order to see the ridiculous variations to which this form of tariff legislation is susceptible. Soon after the Act was passed, gallic acid was included in the list of chemicals in which the duty of 33⅓ per cent. is levied on importation from abroad. The Board of Trade so included it for reasons not disclosed. At any rate, they regarded it as a "fine chemical," that is, a chemical of special purity. Objection was, however, taken, presumably by importers, to its inclusion, so the Board of Trade, again for reasons that we know, took it off. Now comes a chemical manufacturer, Mr. Rose, with his "complaint" that gallic acid (which he manufactures, and also pyrogallic acid from it) is a "fine chemical," and ought to be on the list and be liable to the duty when imported into this country. The Board of Trade, having taken gallic acid off the list, could hardly put it back again by the same official process, for even a Government department has at times a sense of the ridiculous, so it refers the dispute to its officially-appointed referee, Mr. Atkinson, K.C., and Mr. Atkinson has agreed that gallic acid should go back into the list of protected chemicals. It appears quite likely that the

people who objected at the very outset will object to the restoration of gallic acid to the list as a "fine chemical," for it is stated in the "Chemist and Druggist" that they deny having received any notice of the "complaint." What will the Board of Trade and Mr. Atkinson do then? The photographic importance of the case is slight. Gallic acid is used for making pyrogallic acid, the classification of which as a "fine chemical" is not disputed. Mr. Rose, therefore, has the protection of the Act for this product. It would seem that of the two substances, gallic acid (the raw material for his pyro) is the more important to him, since he sets the machinery of the Act in motion in order to make the imported supplies of it more expensive.

* * *

The Success of the Bromide Print. The bromide process, in spite of all the newer printing mediums, still holds pride of place with the serious worker. Many new methods of so-called pictorial reproduction are available, each of them requiring much study and experience, on the part of the worker, to bring out their best possibilities. But the bromide print, easy to manipulate, strong, and yet with perfect gradation, still remains the favourite method of reproduction with exhibitors. At the Royal Photographic Society's exhibition, now open at 35, Russell Square, there are in the pictorial section 154 prints, 115 of which have the name of the printing process attached to the titles in the catalogue. Of these 115 prints, 64 are by the bromide process. Next to this in number is Bromoil (direct and transfer), which claims 24 prints, leaving 27 to be distributed over 9 other printing processes. The bromide process is therefore a long way in front for popularity, and, undoubtedly, the large amount of careful attention given to the manufacture of so many fine grades of paper and speeds of emulsion has had much to do with this. There is no negative nowadays that cannot be suited by some speed or brand of bromide paper, and prints eminently suitable to the full gamut of pictorial subjects may be obtained. The newer grades of warm black paper have become very popular, giving, as they do, fine rich mezzotint effects without the trouble of after-toning. They are specially suitable for portraiture and landscape in the present style; and it is prints on these papers which fill our exhibitions and give so much pleasure to the admirer of photographic craftsmanship.

* * *

Standard Sizes. If we are to draw an inference from a very partial description which appears in the current issue of "Process Work," an American firm, the Chemical Paper Manufacturing Co., of Holyoke, Mass., has either re-discovered or borrowed the idea for a series of standard sizes, which Mr. Alfred Watkins published in the "B. J." of January 2, 1920. It will, perhaps, be remembered that Mr. Watkins pointed out that a rectangle having its two sides in the ratio of 1: $\sqrt{2}$ (*i.e.* 1·414) yields two rectangles of this same proportion of sides when folded on itself. Geometrically, it can be shown that a rectangle of this shape is the only one which exhibits this property. Mr. Watkins adopted it as the basis of a series of rational sizes for photographic plates. The Chemical Paper Co. evidently have a similar aim, since a diagram of theirs shows the successive smaller areas, all of the same shape, obtained by folding the large sheet once, twice and thrice upon itself. But "Process Work" appears to think that this property is obtained, in some unexplained way, by setting off the series of increasing areas from a single point and on a diagonal or hypotenuse common to all of them. It has, in fact, nothing whatever to do with that, but arises only from the 1:1·414 ratio of the basic rectangle adopted for the production of others by enlargement or reduction. The system has merits, particularly in the production of books, and therefore it is no more than fitting that the essential basis of it should be identified with Mr. Watkins's observation of nearly two years ago.

FOCAL LENGTHS AND PLATE SIZES.

A good many years ago the late T. R. Dallmeyer wrote an interesting little book, entitled "A Simple Guide to the Choice of a Lens." It was a curious feature of this publication that, although it was full of valuable information on lens matters generally, there was only one point in it which justified the title. In one place it did recommend the choice for all-round work, of a lens having a focal length equal to the diagonal of the plate upon which it would most often be used. There was, of course, nothing novel in this recommendation. For a score of years previously lenses of the more rapid types had been listed for the various standard sizes of plate on practically this basis, that is to say, the normal focal length for a ¼-plate was 5½ inches; for a 5 x 4, 6 to 6½ inches; for a half-plate, 8¼ inches, and so on. Although it is impossible to trace the origin of this standard, many years of experience have proved its advisability, and the novice in lens buying will do well to be guided by it.

It must not, however, be assumed that there is any fetish in this proportion, for in many cases a much greater comparative focal length will be found to give better results, while in others a shorter one, giving a wider angle, is sometimes demanded by the nature of the subject. It has been urged by some writers that the focal length of the lens should be equal to the distance at which the resulting photograph would be viewed, and that the average distance for people with normal vision being 14 inches, all photographs, no matter what their dimensions, should be taken with a 14-inch lens. This is manifestly absurd, in view of the very large proportion of photographs which are taken upon plates smaller than whole plate, upon which size a 14-inch lens might profitably be employed with most subjects. It must never be forgotten that perspective is governed entirely by the view-point, and is not affected either by the construction or focal length of the lens, provided that the same angle is included. This can be demonstrated by taking one negative with a double lens and, without moving the camera, another with one of the components; upon enlarging the central portion of the first negative until the details are exactly the size of those in the second, it will be found that the outlines exactly coincide.

Wide angle lenses, that is, lenses whose focal length is short in relation to the plates they are used upon, are responsible for much of the bad reputation which photography has earned among artists. The artist, either consciously or instinctively, reconstructs his perspective when he is drawing a subject in a confined position. But the photographer has no such power. Provided that his lens is rectilinear, he is forced to put up with a correct rendering in linear perspective, no matter how offensive to the trained eye it may appear. Wide angles are a necessary evil in many branches of commercial photography; they should be avoided by the artistic worker, unless he has a definite object in employing them.

In classifying lenses no attention should be paid to any descriptive engraving upon the mount. For all practical purposes, the focal length and the extreme size of plate which can be covered are the necessary data; apart from the intensity or speed, these indicate the

limits of their usefulness. For example, a 12-inch wide angle landscape lens, made to cover a 12 x 10 plate, may do more effective service as a narrow-angle lens upon a 7 x 5 or 5 x 4. Conversely, a 5½-inch anastigmat, normally a quarter-plate lens, may be used at a pinch as a wide-angle lens upon a whole plate.

The original type of telephoto lens, especially when of rather low power, is an instrument which has never been appreciated at its true value by the great majority of photographers for either technical or artistic work. Like many other new inventions, it fell into the hands of the "stuntmongers," who strained its capabilities to the utmost, and created an impression that it was unsuitable for everyday work. The great merit of this type is its possession of a variable focal length, so that with the same lens the desired angle can be embraced upon practically any size of plate. With a moderate power attachment the normal plate is covered with a minimum equivalent focal length of three times that of the positive lens. Thus, using an eight-inch rectilinear and a four-inch negative attachment, an equivalent focal length of 24 inches is obtained with a camera extension of eight inches, while for every four inches of camera extension, eight inches are added to the focal length. When objects at a considerable distance have to be taken, there is often a lack of contrast, but this is due to the atmospheric conditions, and not to the lens. It may be minimised by using a slow "contrasty" plate and developing fully.

The modern one-focal-length telephoto lenses, such as the Teleros, Dallon and Cooke, differ only from ordinary lenses in that they only require for distant objects a camera extension of about half their equivalent focal length. These lenses have somewhat limited covering power, and cannot be used for anything like the normal angle, so that it should always be considered whether, in purchasing, say, a 16-inch lens, it would be advantageous to procure an anastigmat which would cover up to 12 x 10, or a telephoto of the same aperture which would cover less than a whole plate.

THE EXHIBITION OF THE ROYAL PHOTOGRAPHIC SOCIETY.

The interest in the exhibition of pictorial and technical photography at 35, Russell Square, shows no signs of waning, and visitors are pouring into the society's house daily in increasing numbers. This is not surprising considering the variety of the work which is being shown and the excellence of the photographic technique. The arrangement of the exhibits this year allows the visitor to obtain full advantage of the various branches of the photography that are represented, and undoubtedly this is helping to a large degree, towards the exhibition's success. To-night, Friday, October 6, Mr. Frank Lambert is lecturing upon "The Beginnings of London," illustrated by lantern slides, and on Tuesday, October 10, Dr. Reginald S. Clay will deliver the twenty-fifth annual Traill-Taylor memorial lecture. His subject will be "The Development of the Photographic Lens, from the Historical Point of View." On Friday, October 13, Dr. C. Atkin Swan will deliver an illustrated lecture, "Carcassonne and the Pyrenees," a subject in which Dr. Atkin Swan is particularly well versed.

We are publishing below a full review of the natural history section of the exhibition by Mr. Harold Hurden. This branch of photographic work, calls, perhaps, for greater care and patience, coupled with skill and endurance, than any other branch of the art, and it is only by prolonged study and minute attention to details that photographs of the kind and quality shown in this section of the exhibition are obtained.

THE NATURAL HISTORY SECTION.

Whether it is due to a rigorous selection, or whether the standard of work has so much improved, it is certain that the collection of prints in this section, now for the first time given a room to itself on the ground floor at the Society's home, at 35, Russell Square, is the best that has ever been gathered together in an exhibition. The high technical standard of the photographs is beyond question. It is probable that the exhibitors are not all naturalists in the purely student sense. One can detect subjects whose appeal has been from sheer beauty. Others suggest more the delight of the sportsman, the courage and patience of the man who delights to take risks. Can anything be more exciting, and at once more incongruous, that riding alongside a herd of wild, galloping giraffes in a Ford car? The very idea must raise a smile. But M. Maxwell's work, No. 267, is by no means funny. It is a wonderful photograph of three wild giraffes taken in precisely these circumstances, and it sadly upsets the layman's idea of the gait of these animals. It cannot be the privilege of many to see so unique a sight, and it comes as a great surprise to note that the galloping gait is so different to the trot. With this beautiful creature now little more than a survival, one can but hope that Mr. Maxwell is more zoologist than hunter. The courage required to snapshot a wild bull elephant at eight yards range is brought forcibly to our minds on viewing another of Mr. Maxwell's prints, No. 266.

Of 116 prints in this section, ornithology claims almost exactly half. This is, perhaps, inevitable if we consider the appeals which natural history subjects can make to photographers: and it emphasises the point that the exhibitors are for the most part photographers first, and naturalists afterwards. Botany might have claimed more than it has, if beauty were the only appeal; but the birds present just that combination of beauty of subject, with patience, stealth, and no small measure of courage, which is so satisfying to the primitive hunter instinct. It may be that the pure naturalist can be more looked for in other branches of natural science. The arachnoids are not beautiful, but the value of Hugh Main's works, 158, 159, and 160 is beyond doubt, as is that of some others of his. Nor are toads beautiful, but Dr. Rodman's "Spanish Toad" (214) is a beautiful photograph, which is not just the same thing. It is doubtful, however, if the lens he uses is quite the instrument for this kind of work. The fine rendering of "Rust Red Anemone," 185, and "Pale Pink Anemone," 188, both by Alan V. Insole, should be noted. Dr. J. B. Pardoe's "Black Snake," 225a, is especially good, and his "Snapping Turtle and Frog," 186, though rather dreadful, is a valuable record. Anything which can be done to make the forms and life history of our garden pests more familiar to us is of the utmost value, and E. A. Robins' three prints, 180, 181, and 182, of "The Gooseberry Sawfly and its Eggs and Larva," are good examples of this class of subject. There are some good photographs of moths and butterflies, of which E. J. Bedford's "Red Admiral" (196), is particularly soft and attractive.

In the zoological section Miss M. A. Booth has a panel of nine prints (No. 157), of a "Mother Squirrel and some of her Offspring," quite delightful studies of this little animal now so familiar to Londoners. By the way, Miss Booth appears to be the only lady exhibitor in the natural history section. W. H. Hadley has achieved something of more than natural history interest in his two prints of "Lions" (210 and 215). They have more than usual pictorial value, as has Dr. Pardoe's "Ever Watchful" (262)—a herd of deer under a tree. This is beautiful photography. No. 251, "Marmotte from the Mountains of Savoy," is noteworthy of such a shy creature. The botanists have not so many works as might have been expected. Their usual flower study is conspicuous by its absence, but scarcely anything could be finer work than F. G. Tutton's two studies of "Japanese Peonies" (193 and 203), in which he has retained the delicate texture of the petals in a most mas-

terly way. In 107, "Bladder Campion," J. A. Sharpe shows two pretty prints of this familiar British plant. Other exhibitors in this group are E. J. Bedford, with amongst others, the rare "Lizard Orchid" (104), and John J. Schoonhoven with "Broom Rape" (183), and "Indian Pipe" (134), two useful contributions to pictorial botany. J. A. Sharpe also shows some fungi (174, 204 and 212)—tributes to his skill in colour rendering. Dr. Hastings's "Soil Formation on the Alps" (240), is a capital lesson in progressive soil formation, in which he illustrates by nine prints the progression from crustaceous lichens to the Alpine meadow. This is also good geology.

It is to the ornithologists that the medal has fallen, and no quarrel can be with the selection committee for their award to Ralph Chislett for his "Variations in the Plumage of the Arctic Skua" (No. 243). In six delicate and almost perfect studies of this bird, Mr. Chislett has recorded some of its plumage variations with consummate skill. It is fine photography and good natural history. Mr. Chislett has other prints in this section, which should not be overlooked. Capt. Knight well sustains his reputation with three fine prints. No. 219, "Female Sparrow Hawk at Nest," deserves special mention. The beautiful pose of this bird is most arresting, and the picture is of great merit. No. 235, "The Life History of the Night Jar," by T. M. Blackman, is a series of six fascinating photographs which, apart from their other merits, must be hard to beat as a natural history record. The difficulties overcome so successfully in this work must have been great. Mr. Blackman has another excellent print in No. 205, "Meadow Pipit Feeding Young Cuckoo." This has, of course, been done before, but that scarcely lessens the interest in this study. C. J. King has a similar subject in No. 211. In this case the foster mother is a Rock Pipit. In 239 and 241, "The Herald of the Dawn," and "The Warden of the Marshes," H. M. Salmon shows two pleasant little pictures of no mean pictorial interest. Dr. Pardoe's fine bird studies will appeal to almost everybody. His quaint "Wood Pile" (259), is an especially clever composition of an owl sitting on the shaft of an axe driven into a log. His "Blue Jays" (200), should also be seen. Two other studies of Jays should be mentioned; No. 168, by S. Crook, and No. 201A, by T. M. Fowler. In each the plumage colour has been well suggested, but Mr. Fowler's print gives the more pleasing definition for such work. Colour rendering of a high order is seen in T. Robinson's "Yellow Wagtail" (202). W. J. Palmer exhibits photographs of resident and migratory birds. "The Wryneck" (255) is, perhaps, commoner in the home counties than anywhere else in Britain, and this is a good example. Oswald J. Wilkinson's works are, as elsewhere, of a high standard, and are valuable contributions alike to natural history and photography. His "Warblers" (169 and 170) are particularly fine. Good work is also shown by Jasper A. Atkinson, E. Smithalls, G. C. S. Ingram (the latter's "Reedwarblers and Young" (216) is noteworthy) and E. J. Bedford, whose soft and pleasant print of "Robin" (197), strikes just the right note in a British exhibition. Much of the work in this room could equally well have been hung in the pictorial section. It demands, moreover, many rare qualities in a photographer.

HAROLD HURDEN.

DEATH OF MAJOR-GENERAL WATERHOUSE.

WE very much regret to announce the death, on Thursday in last week, September 28, of Major-General James Waterhouse, in his 81st year. He was buried in the graveyard of Eltham Parish Church, on Tuesday last, when the ceremony took the form of a full military funeral, attended by the band of the Royal Artillery.

General Waterhouse, late Assistant Surveyor-General of India, was born July 24, 1842, and received his education at University College School and King's College, London.

In 1859 he joined the Bengal Artillery, and spent the following 38 years in the Indian Army, during which time photography played no unimportant part in his eventful career. In 1861-2 he was commissioned to photograph the native tribes of Central India, and during the next few years was stationed in many places, including Saugor, Delhi, various hill stations and Allahabad, till June, 1866, when he was transferred to the Bengal Staff Corps, and a month later appointed to the charge of the photographic operations in the Surveyor General's Office at Calcutta, which post he held till his retirement in 1897.

Before taking up this work, however, Major-General Waterhouse spent five months in the offices of the Great Trigonometrical Survey at Dehra Dun, in order to undergo a course of training in photo-zincography, finally taking up his duties in Calcutta in November, 1866.

During the period of more than 30 years in which Major-General Waterhouse occupied this important post he worked out officially many improvements in photo-zincography, photo-collotype, and other processes of reproduction used in the office, and introduced the waxed sand process of heliogravure. He also took part in several important expeditions, being deputed to assist Colonel J. F. Tennant, R.E., in photographing the total eclipse of the sun at Dodabetta in December, 1871, also the transit of Venus in December, 1874, and was in charge of the Indian Eclipse Expedition to Camorta in 1875.

During his residence in Calcutta General Waterhouse did much valuable experimental work. He was the first to experiment with eosine as a colour-sensitiser. This was in 1875, when he published his results as to its properties in rendering haloid salts of silver sensitive to yellow light. Another of his important discoveries was the extreme sensitiveness for the red and ultra-red spectrum imparted to gelatine dry-plates by an ammoniacal solution of alizarine blue.

In 1890 he was awarded the Progress Medal of the Royal Photographic Society for his spectrographic observations of the action of dyes on dry plates and for orthochromatic photography, and in the same year discovered and investigated the curious action of small quantities of thiocarbamide added to an alkaline developer in reversing the photographic image on dry plates, and showed its application to photo-engraving.

Photograph by H. Wayland.
THE LATE MAJOR-GENERAL WATERHOUSE.

In 1893 he investigated the electrical action of light upon silver, the results of which were published in the "Journal of the Bengal Asiatic Society," and in 1895 was awarded a Voigtländer medal by the Vienna Photographic Society for his researches in scientific photography.

Since his return to Europe in 1897 General Waterhouse had carried out a number of investigations relating to the scientific side of photography, including the sensitiveness to light of silver and some other metals and the direct *visible* images obtained thereon, and had made several interesting discoveries regarding the early history of the camera-obscura, the telephotographic lens, and photography with salts of silver. Many of his results have been published in the pages of "The Photographic Journal," "The British Journal of Photography," and other technical and scientific papers.

General Waterhouse was president of the Royal Photographic Society in the years 1905 to 1907, a period when the politics of the Society were by no means quiet, and probably were not particularly congenial to one of his peaceful temperament. A man of a most amiable and modest nature, his passing will be deeply regretted by the great number of those of the older generation in photography who had occasion to benefit from his great stores of knowledge and his invariable readiness to lay them at the disposal of inquirers.

SELF-TONING PAPER FOR PROFESSIONAL PORTRAITURE.

Self-toning papers appear not to have found a firm footing in the printing departments attached to the studios of our leading portraitists. Introduced primarily for the labour-saving amateur worker, the majority of professional workers appear to be content to let the amateur have the paper and to consider it his own, indeed, I have heard of some professional workers who have considered it to be *infra dignitatem* to confess an admiration for self-toning paper.

The makers of Seltona have perhaps done more than any other in the way of encouraging professional portraitists to use self-toning papers and have undoubtedly reaped the greatest benefit. The excellent examples of studio portraiture (nicely finished, and in folders as a progressive professional would produce them), issued by the manufacturers of Seltona, have no doubt led many workers to adopt the paper. But much more remains to be done by some of the other makers in producing perfect papers before their products will occupy the positions they deserve to take up in the workrooms of professional portraitists.

Many photographers have given self-toning paper a trial and have not secured the good results they expected to get, results which perhaps would not sustain the reputation they have worked hard to secure. What the photographer requires to do is not to experiment with one paper, but with several, selecting those as widely different as possible from each other and to keep to the one that suits and gives the best results from his negatives. There is a wide difference between some of the different makes of paper, and selecting one at random does not always prove satisfactory. The type of negative is an important factor, the negative doing much to govern the final tone of the prints. There are no bad British-made self-toning papers on the market, but some are far more suitable for a given negative than are others, especially when the paper is manipulated in the simplest manner possible, i.e., without the alternative manipulations many makers suggest.

As is well known, practically every make of paper will give a series of tones by varying the treatment, but the much boomed—and real—charm of self-toning paper is its simplicity, and if one is compelled to treat a paper somewhat elaborately to get the tone wanted, one may almost as well keep to ordinary P.O.P. and gold toning.

Rather than play about with preliminary or supplementary baths, along with hypo solutions of various strengths and times of immersion, I suggest that the worker try three or four different makes, adopting for each the simple and time-saving manipulations recommended by each maker, and use that which suits him, or rather suits the type of studio negative he is in the habit of producing.

As all makes of paper are good it is perhaps a little invidious to recommend any particular make, but to those who wish to make trials in the manner I have suggested I would recommend either Seltona or Paget Matt along with either Barnet "Bartona" or Griffin's "Goldona" glossy. The two matt papers are of the collodion type, while the two glossy papers are gelatine. And I may here remark that whatever make of self-toning paper the portraitist may use he will find the glossy gelatines and the matt collodions of the greatest service.

One of the common complaints about self-toning paper for professional work is the difficulty of getting, say, a dozen portrait-prints of the same tone, or of getting to-day a tone exactly like that secured yesterday. But I have never considered this a serious drawback, and have rarely met with it. When the trouble does arise it is generally caused by attempting to treat too many prints in the same lot of hypo solution. Obviously, a twelfth print placed in a dish of solution in which there are eleven others will not be attacked by exactly the same kind of solution that the first print met with; hence some variation of tone. Better to treat a smaller number of prints in a corresponding smaller quantity of solution.

Many failures with self-toning paper in the past have no doubt been attributable to faulty hypo, but hypo is better to-day than it has been for the past seven years or so, and bad samples are now rare. The best hypo for self-toning paper is that known as "pea crystal," the commoner and rough variety being at times a little too impure for self-toning paper, though serviceable enough for negative and bromide paper work. Alkalinity of bath is so important for good work with all self-toning papers that testing with litmus paper is desirable; the fixing bath should turn red litmus paper to a blue, and should there be any uncertainty, proper alkalinity may be assured by adding a little bicarbonate of soda to the hypo solution.

PRACTITIONER.

THE SAFEGUARDING OF INDUSTRIES ACT AND FINE CHEMICALS.

On Tuesday, September 26, a case under Part I. of the Safeguarding of Industries Act of interest to the photographic industry was heard by the Referee. It may be explained that under Part I. of the Act the Board of Trade has issued a list of many hundreds of substances, including large numbers of chemicals, which are dutiable when imported from abroad. Objections to the inclusion in, or exclusion from, this list are heard by Mr. Cyril Atkinson, K.C., who has been appointed Referee for this purpose. Generally speaking, the list issued by the Board of Trade includes all fine chemicals, and thus most, if not all, photographic chemicals are dutiable under the Act. The case in question, however, concerned gallic acid, and the circumstances attending it serve to illustrate the difficulties of administering the Act, so far as the Board of Trade is concerned.

Gallic acid, of course, is obtained as a stage in the manufacture of pyrogallic acid, and at the time of the "complaint," reported below, whereas pyrogallic acid was, and still is, on the list of protected substances, gallic acid had been excluded from the list. When the list was originally published, towards the end of last year, gallic acid was included, but owing to complaints, presumably by importers, the Board of Trade was induced to remove gallic acid from the list of dutiable articles under the Act. This immediately brought a protest from the manufacturers in this country, and, apparently in a dilemma, the Board of Trade thought it best to leave the decision to the Referee.

The complainant was Mr. J. L. Rose, of Abbey Road, Barking, who commenced the manufacture of gallic acid, pyrogallic acid and gallamide in 1914, when there was a shortage of gallic acid owing to the fact that there had been no manufacture of it in this country for 30 or 40 years, all our supplies having been imported from Germany. Although perhaps it need hardly be explained here, gallic acid is made from gall nuts, which are excrescences formed on oak trees, the result of the puncture of the oak by an insect. The tree, in endeavouring to deal with the parasite, forms an excrescence or small round knob about the size of an oak apple.

Mr. Rose explained, *in camera*, his method of manufacturing gallic acid, and also at the same time gave information as to the size and nature of his plant, output, etc. He claimed that the manufacture of gallic acid is essentially a fine chemical manufacture, and although the Board of Trade originally took the same view, it now argued before the Referee—not too confidently, it must be admitted—that the manufacture is more in the nature of that of a heavy chemical. Strictly speaking, the Board of Trade—or rather the responsible officials—still held to their original view that gallic acid is a fine chemical, but having removed it from the list on the ground that it is a heavy chemical, the position was bound to be defended.

In all previous cases which the Referee has heard—and the majority have related to chemicals—he has endeavoured to come to a decision from an examination of the manner in which the trade has treated the particular substance in the past, and following the same line in this case, after hearing evidence from Mr. C. A. Hill, the managing director of British Drug Houses, Ltd., he said he was satisfied that the trade had always regarded gallic acid as a fine chemical. Whilst intimating a decision in favour of the complainant, the Referee said he would give a considered decision in writing. It should be mentioned that although those who had originally successfully argued to the Board of Trade that gallic acid is not a fine chemical had been notified of the proceedings, nobody put in an appearance in opposition.

Mr. W. J. U. Woolcock, M.P., general manager of the Association of British Chemical Manufacturers, who presented the case for Mr. Rose, made the strong point that the Safeguarding of Industries Act was specially intended to protect industries that had been started in this country since the war, and that here was

case in which the particular substance had not been made in England for 30 or 40 years, but the manufacture of which had been begun to meet the needs of the nation owing to foreign supplies being cut off by the war.

THE EXTRA SMALL STOP.

When a small object is to be photographed which contains a wealth of fine detail in several planes one has a choice of methods, supposing that the detail is required to be rendered sharp throughout. For this sort of subject a lens of too short a focal length must not be used, or the violence of perspective becomes noticeable. That is to say that whatever lens one uses the diameter of the image should not exceed half the focal length, so that one usually is compelled to be satisfied with a comparatively small image which can be enlarged as required afterwards.

It became necessary to arrange a standard output for continuous work of this kind. Enlarging was ruled out, first, because very fine detail is not improved thereby and it was essential to have negatives not only very well blocked out, but also available for printing at a moment's notice at any time. The subjects also were such as to render the production of really good enlargements a matter for anything but hurried procedure. Therefore whole-plate contact work was decided upon. Now, anyone who has ever focussed upon a large head, for instance, on a whole-plate knows that even with a comparatively small stop all details are never microscopically sharp. In fact, in the work in question (a large series of scientific instruments) so great was the depth required that even *f*/64 was not small enough, using a 13-inch lens upon the whole-plate. Therefore the diaphragm of the lens was altered (simply by lengthening the slot in the mount slightly) so that two stops smaller could be obtained, viz., *f*/90 and *f*/128.

As in many cases the objects were photographed from half to full size the actual extension of the camera varied from 150 per cent. to 200 per cent. of the lens focus, so that the actual aperture went down to as low as *f* 180 and even *f*/256. The oft-repeated dictum that below *f* 70 a lens begins to give less sharpness was found to be a groundless superstition. As the subjects themselves were in part very dark in character, and a filter was almost always used the exposures were comparatively long ones. Both for this reason and because of the dimness of the image reaching the plate, it was found necessary to carry out this work when the light was reasonably favourable, otherwise prints were liable to be disappointing.

Focussing at times was a matter of great difficulty. All the various movements of the camera were frequently brought into play in order to get a particular view-point while retaining perpendiculars, as well as getting the plane right which would procure the best all-over sharpness when stopped down. Owing to the long exposures, and the number of articles that had sometimes to be taken in a limited time, the smallest stops could not be used indiscriminately, and it was found that the extra trouble involved in the careful focussing was more than balanced in the time eventually saved. At the same time it was not found possible to select this plane by any mathematical method because hardly ever was the axis of the lens anything like perpendicular or central with the plate, and character of the subjects was usually too complicated also.

As soon as the diaphragm began to be turned below *f*/22 it became increasingly difficult to know when the various details were getting sharp, even when using a magnifier that allowed one to examine the image at the best angle for a bright vision. A device was at length evolved to overcome this difficulty. A few 4-volt bulbs, were bought such as are used in pocket "flash-lamps." The holders for these had each a length of flex about eighteen inches long and at each loose end of the wire a spring clip was soldered. Simply by placing a bulb at each of the outside points of the article, either by just laying it down, or if necessary by twisting the flex round a projection, and temporarily clipping the other ends to the terminals of a battery it became possible to see each tiny filament growing brightly, however small the stop, and so observe when each became sharp.

The whole electric outfit packed into a match-box and a battery could always be borrowed where such goods as those described were to be photographed. When calculating exposures for these very small apertures it became necessary to take into consideration not only the nominal aperture as marked, but also its actual value in accordance with the distance from lens to plate. Then the nature of the subject and of the strength of light had to be accounted for. By this I do not mean merely the meter-reading, but that just as in colour-work a meter-given exposure in a poor light has to be multiplied considerably if a satisfactory negative is hoped for, and with dark subjects all the more so. It must be remembered too that with such tiny stops as those described even in a good light the actual illumination reaching the plate is very dim indeed when such subjects are photographed through colour-filters, and the extra allowance should be made even if the light outside the camera seems bright. The old motto of giving a little extra "for luck," however, is far better if translated into a scientific method of calculation. This may be done by means of a few trial exposures, from which definite facts may be deduced and the results applied to any particular case that may arise. D. Charles.

Assistants' Notes.

Notes by and for assistants will be considered for this column. Payment for accepted contributions is made on the first of the month following publication.

Legal Photography.

The craze for speed seems to have infected even the legal profession. The rapidity with which photography can be executed (and is daily carried out in newspaper work) has apparently impressed the business world, so that results frequently are demanded within a few hours of the order being placed, and sometimes even in less time. The fear of losing an order may cause the acceptance of a job to be done under rush conditions, but the opportunity should not be lost of pointing out the advantage of giving longer notice for such work.

It is so little known (outside the profession) that a photographer can easily diminish the strength of a case by carelessly made photographs, or by having to make them under adverse conditions of light and time.

Of instances that occur from my own experience, the case of a cyclist who was thrown by a tram line standing up above a bit of road is, perhaps, the clearest. A photograph, made immediately on receipt of the instructions, taken from eye level in the light of the diffused afternoon sun, gave no appearance at all of relief to the alleged raised rail. By waiting till night, and taking the photograph from a low view-point by the light from an acetylene cycle-lamp, a result was obtained that exaggerated, if anything, the cyclist's case.

Another case that depended partly on photography was a collision dispute in which the point at issue was which of two cross-roads was the main (or more important) road and entitled to precedence as regards traffic. Here choice of view-point and of suitable focal length of lens were factors essential to helpfulness to one's client. Instances could be multiplied, but lawyers, and especially their clerks, need some tactful education to the effect that a little information as to the points of the case, and the granting of some measure of discretion, may result in greater chances of a win. Legal photography is, in short, not an automatic process any more than portraiture is.—D. C.

Printing from Line Negatives.

It is not too well known that gaslight paper shows marked superiority over bromide for the purpose of printing from line negatives. Not only does the slow paper give a pure black line with greater ease and latitude of exposure and development, but the gaslight class of emulsion has the property of retaining a perfectly clean edge to a line no matter how grossly over-exposed it may be. Bromide paper, on the other hand, irradiates to a slight but noticeable extent on the slightest provocation.

In many line negatives some parts are slightly veiled, and an exposure sufficient to give a good black in these portions would tend to thicken the clearer lines. In gaslight, provided proper contact is secured, this is never the case. Much the same remarks apply to the making of diagram lantern-slides, but here a word of caution is necessary. A negative which has portions showing a distinct veil proves difficult to print on a lantern plate of the gaslight variety without very prolonged exposures. Although the clearer lines do not actually thicken up by spreading any more than in a paper print, halation is very liable to occur owing to the great transparency of the emulsion.—D. C.

The Side-Swing for Field Cameras.

The studio camera, as compared with the instrument for outdoor use, has very few movements, but on the better makes there is one adjustment that it possesses almost exclusively, viz., the side-swing of the back. Yet in outdoor work such a movement is at least as useful as it is in the studio. Perspective views of buildings and cars are only two instances of many that must occur to the mind of any commercial operator.

Many field cameras, merely by reason of the looseness of the sliding pieces connecting the back to the baseboard, permit of a limited amount of side-swing, but if an equally small degree of swing be contrived for the *front* a great power is placed in the photographer's hands in quite a surprising number of subjects. Quite apart from the shortened exposures due to less need for small stops there is in practice a gain in sharpness which is better than that obtained by stopping down. When enlarging, the difference is often very marked.—D. C.

FORTHCOMING EXHIBITIONS.

September 9 to October 7.—London Salon of Photography. Particulars from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 18 to October 28.—Royal Photographic Society Annual Exhibition. Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

October 18 to 21.—Rotherham Photographic Society. Hon. Secretary, S. G. Liversidge, Orissa, Gerard Road, Rotherham.

October 18 to 28.—Portsmouth Camera Club. Latest dates: Entry forms, October 11; exhibits, October 16. Particulars from the Hon. Secretary, C. C. Davies, 25, Stubbington Avenue, North End, Portsmouth.

1923.

February 5 to March 3.—Northern Photographic Exhibition, City Art Gallery, Manchester. Latest date for entries, January 12. Particulars from the Hon. Exhibition Secretary, Walter Johnson, 30, Hartington Road, Chorlton-cum-Hardy, Manchester.

March 2 to 31.—Pittsburgh Salon of Photography. Latest date, February 5. Secretary, Charles K. Archer, 1,412, Carnegie Building, Pittsburgh, Pa., U.S.A.

March 13 to 16.—Exeter and West of England Photographic Exhibition. Particulars from the Hon. Secretary, Frederic G. Tutton, 9, Union Road, Pennsylvania, Exeter.

March 16 to 24.—Photographic Fair, Holland Park Hall. Secretary, Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications September 4 to 9:—

Shutters.—No. 24,360. Shutters for photographic cameras. A. J. Dennis, V. W. Edwards, and Houghton-Butcher Manufacturing Co., Ltd.

Colour Photography.—No. 24,214. Colour photography. M. Roth.

Applications, September 11 to 16:—

Cameras.—No. 25,012. Cameras. A. E. Norton.

Photography.—No. 24,940. Photography. W. P. Carpmael (H. C. J. Deeks).

Development.—No. 24,512. Apparatus for development of photographic films. J. H. Jackson.

Plate Storage.—No. 24,663. Box for storage of photographic plates, records, etc. E. H. Masters.

Applications, September 18 to 23.

Cameras.—No. 25,797. Photographic cameras. Optische Anstalt C. P. Goerz Akt.-Ges. and F. Weidert.

Focussing Devices.—No. 25,375. Focussing devices for cameras. P. H. C. Redders and F. Torka.

Camera Stands.—No. 25,119. Photographic camera stand. E. H. Mills.

Colour Photography.—No. 25,565. Production of transparencies in natural colours. L. C. Rudkin.

Colour Cinematography.—No. 25,675. Colour cinematography. D.C.L. Syndicate, Ltd., and F. W. Donisthorpe.

Colour Cinematography.—No. 25,553. Preparation of multi-coloured screens for colour cinematography, etc. G. Frost.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

Composite Plates for Indirect Colour Photography.—No. 183,189 (March 19 1921). The invention describes a process for preparing three separate colour sensitive emulsions, coated on one support in such a way that one exposure is necessary to produce the three negatives. The films may be separated for development, and each film developed as a separate exposure. A glass plate coated with sensitive emulsion is taken as the rigid support, and two thin colour sensitive films are pressed into contact with this by means of rollers.—Ernst August Lage, 162, Wandsbeckerchaussee, Hamburg, Germany. (Further particulars of this process are given on another page in the "Colour Photography" Supplement.

Two Colour Colour Cinematography.—No. 183,150 (November 4, 1921). The invention describes the apparatus necessary for the production of two-colour cinematograph films, in which a disc is utilised having an aperture admitting white light, which has a phase of blue filter attached, and also a section of red filter. The blue filter or phase attached to the aperture admitting white light is intended to increase the colour value on the blue side, and the filter can be varied in area or intensity to suit any particular condition of light or nature of subject. The red filter is graded in depth, and exposure commences through the densest end, the amount of light passing being gradually increased in intensity as the disc moves forward. It is claimed that more perfect blending of colours is obtained by this invention, and that it is now possible to make colour films by normal artificial light.—Roland Oliphant Percy Humphrey, New Hibernia Chambers, London Bridge S.E.1, and Claude Harrison Friese-Greene, 32, Crescent Road, Bromley, Kent.

(Further particulars of this invention are given on another page in the "Colour Photography" Supplement.)

The following complete specifications are open to public inspection before acceptance:—

Colour Cinematography.—No. 185,386. Process and apparatus for making coloured or uncoloured cinematograph pictures and for reproducing cinematograph films. R. H. C. Koumans.

Projection Process.—No. 185,395. Process for diascopic and episcopic projection. E. Liesegang.

Trade Names and Marks.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register:—

Kima.—No. 424,732. Scientific instruments included in Class 8. W. Watson & Sons, Ltd., 313, High Holborn, London, W.C.1, manufacturing opticians.

Oro.—No. 424,837. Photographic paper, photographic albums and photographic mounts included in class 39. Thomas Illingworth & Co., Ltd., Cumberland Avenue, Park Royal, Willesden Junction, London, N.W.10.

New Books.

Studio Advertising for Photographers. London: Houghtons, Ltd. 2s. 6d.

While schemes of national advertising of portrait photographs are being talked about, it is nevertheless true that they cannot render altogether unnecessary individual advertising by photographers in their local newspapers. On the contrary, local advertisements form a supplement to any national scheme which may be devised and themselves benefit by the stimulation of public interest which would be created by a general campaign of Press publicity. But, apart from these considerations, a very useful purpose is served by the compilation of typical Press advertisements for photographic studios which Messrs. Houghtons have made and published. The little book contains a score or two of advertisements attractively worded and set up in types which are commonly employed in newspaper offices. Moreover, they are arranged for various sizes and shapes of display, from small panels to be inserted in a 2-inch or a 3-inch column up to larger announcements occupying spaces such as 4½ x 6 inches. It is hardly necessary to say that any of the smaller ones could be set up by a local printer in larger size, and *vice versa*, but as they stand the series represents a very well selected set of announcements from which a photographer can choose according to his fancy. The wordings of the advertisements make use of such inducements as the charm of babies and children, photographs as birthday and Christmas presents, photographs of homes and gardens, animals and motor cars, and sports subjects. They are printed on one side of the paper only, so that the user has simply to tear out a particular announcement along the perforations in order to be provided with the "copy" for his newspaper. One or two of them make use of line illustrations, stereos of which are obtainable from Messrs. Houghtons. We are quite sure that no photographer who does any Press advertising will regret paying half-a-crown for this very useful volume.

L'Indicateur de l'Industrie Photographie. Paris: Paul Montel, 18 francs.

The publishing house directed by M. Paul Montel, 35 Boulevard St. Jacques, Paris, has issued a large book of 390 pages which provides a conspectus of the photographic trade in France and several other Continental countries, and also a directory of professional photographers and dealers in the same regions. It is very clearly divided into definite sections. First come lists of professional photographers in Paris, in the Seine Department, and in the other Departments of France, and in the French Colonies and Dependencies. Similar lists follow of dealers in photographic requisites. There are also directories of professional photographers and dealers in Belgium, Switzerland, Holland, Luxembourg, and a few addresses of presumably French portraitists and dealers in, chiefly, the Latin countries in Europe and South America.

Perhaps the parts of the volume which provide a survey of the manufacturing and wholesaling trade in France are those which will be of chief service to people in the industry in this country. There is first of all a list of the chief goods (apparatus and materials) of the photographic trade with the names and addresses in the case of each of firms who manufacture or supply. This is followed by an alphabetical list of the trade marks of photographic goods, each identified by a brief statement of the nature of the goods themselves to which the mark applies and of the name and address of the supplying firm. This list is by no means limited to French goods. The volume is completed by brief particulars of the various trade associations in France and by a list of the chief French photographic societies. M. Montel is to be congratulated upon having produced a volume which will take its place as a standard work of reference for those having dealings, in the way of photographic trade, with firms or individuals in France.

Eastman Research Laboratory Papers. Rochester, N.Y.: Eastman Kodak Co.

One welcomes the fourth volume of the "Abridged Scientific Publications" which are published by the Research Laboratory of the Eastman Kodak Co. as a somewhat condensed record of the many scientific communications which have been published by the Laboratory. The present volume contains those published during the years 1919 and 1920. These include 34 papers, most of them dealing either with photographic chemistry or with the properties of gelatine. It is a very great convenience for the student of the progress of scientific investigation in photography to have such a periodical official record of the work which has been carried out by Dr. Mees and his collaborators. Moreover, in the present volume the compilers have taken the opportunity of providing several complete indexes to the whole series of 117 papers which have been published since the establishment of the Laboratory. One of these indexes is arranged according to author; a second is one in which the papers are classified according to their subjects, and a third is a chronological list of the communications, giving in each case a reference to the journal in which the full communication was first published. No price is marked on the volume before us; we believe that the Eastman Research Laboratory is ready to send a copy to investigators or students able to make use of it.

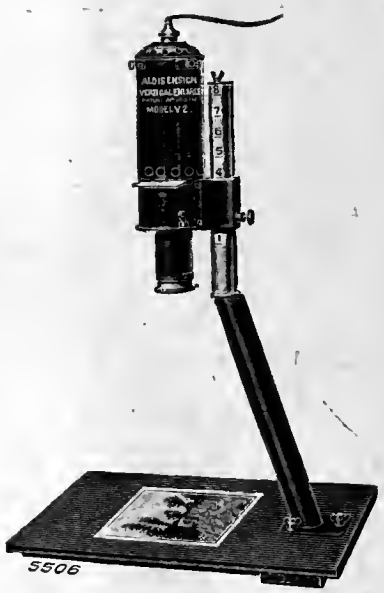
My Five Shilling Camera. By S. N. Sedgwick, M.A. London: Religious Tract Society. 5s. net.

The idea of a course of instruction in the making and use of a photographic equipment in the shape of a series of letters between uncle and nephew is probably an innovation in the planning of a photographic text-book. The present volume takes this form. If we grant the basic assumption that cameras are so dear as to be beyond the means of the father who sends his boy to a boarding-school, well, the arguments of our uncle-author hold good. Perhaps, however, it is not by chance that Mr. Sedgwick makes the uncle a sufferer from malaria, acquired in the East, and therefore liable to take a somewhat jaundiced view of things. Despite the essential wrongness of the assumptions on which the volume is based, there is a good deal to commend in it as regards the practical instruction which it gives in the home-making of a camera, stand, and enlarging camera. These appliances, of course, are of the most primitive kind. No doubt there are boys who will find enjoyment in making them and would not be added to the ranks of amateur photographers but for travelling along this channel. But such must surely be very few in number.

New Apparatus.

Aldis-Ensign Vertical Enlarger. Sold by Houghtons, Ltd., 88-89, High Holborn, London, W.C.2.

THE apparatus available for enlarging nowadays has undergone a complete change and, from the old horizontal type of lantern, has become a compact, easily adjusted vertical model. This



Aldis-Ensign Vertical Enlarger Adjustable Model.

type of enlarger is gaining rapidly in favour, owing principally to the simplicity of its construction and the ease with which it can be worked. It is no longer necessary for a separate

easel to be used, this necessary part now being formed in the base-board of the apparatus, making the unit quite complete in itself. The Aldis-Ensign vertical enlarger, which has just been placed upon the market by Messrs. Houghtons, is the latest addition to this type. It consists of a tubular body attached to an upright brass rod, which is firmly fixed to the base-board. The body of the lantern, which is strongly made in metal, contains a "diffusing" condenser above which is placed the illuminant, which can be either electric or incandescent gas. The makers emphasise the fact that these are the only patterns of vertical enlarger fitted with condensers, and thus permitting the shorter exposures characteristic of this system of illumination. The metal body slides on the brass rod, on which are engraved numbers from 1 to 8, which numbers are repeated upon the lens tube. By fixing the body of the lantern to, say, figure 8 and the lens tube also to the same number, a perfectly sharp picture is given upon the base-board. The size of the picture may therefore be adjusted to requirements by simply fixing the body and the lens tube at similar numbers. An additional advantage of the Aldis-Ensign vertical enlarger is the enclosed orange cap, which is placed on or off by moving a lever fitted on the outside of the lantern body. The V2 type enlarger is made to take 3¼ × 2¼ film or a large portion of a ½ plate, and is supplied with a folding

Aldis-Ensign Vertical Enlarger Fixed Focus Model.

glass carrier, which enables the film to be kept quite flat. The full enlargement obtainable by this model is 14 in. × 10 in., and the price complete, fitted for gas or electric light, and with an Aldis Plano f 7.7 Anastigmat, is £7 17s. 6d. The electric lamp required is a 60-watt gas filled bulb, of the short pattern now in general use. The lamp for electric and the mantle for gas are not included in the outfit, owing to the difficulty of transport.

Two other types of the enlarger are supplied. The F1 model is of fixed focus, and admits of postcard enlargements being made from V.P.K. or No. 1 Ensignette films. Its price complete, but without electric lamp or gas mantle, is £2 12s. 6d. For enlarging to 6½ × 4½ there is the F2 model. This also is of fixed focus, and takes film of 3¼ × 2¼ size or portions of ½-plates; the price of this model is £3 3s. All three enlargers are focussed at the Aldis optical works, and this fact, coupled with the excellent name Messrs. Houghtons have for photographic apparatus of all kinds, must recommend the new Aldis-Ensign enlargers to all photographers.

More Camera Smuggling.—At the Dover Police Court last Thursday a man was fined £70 for smuggling a camera, films, etc., from Belgium.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

CROYDON CAMERA CLUB.

Mr. Vivian Jobling gave a capital lecture-demonstration on "Paints, Varnishes and Cements," much of photographic application. He certainly objected to the secretary having inserted the last item, and concluded it was done in the vain hope of recovering lost youth. The practical usefulness of the lecture is indicated by the following account (comprising only the major part) which has been written in staccato fashion for brevity's sake.

He started with a short reference to ordinary paints and the various brushes used in their application. The best way to clean them, he said, is to rinse well in turpentine and then wash in warm soap and water. Turpentine alone, more or less, leaves the brush stiff. Benzol (not petrol) makes a good and cheap substitute. He strongly advised that all paints and varnishes should be purchased in fair quantities from a reputable warehouse (avoiding the luncheon hour) such as Farmiloe's in Rochester Row, Westminster. Buying anywhere in small tins and bottles is a more expensive proceeding.

Aluminium paint is, he said, very useful for many purposes, and he was surprised it was not more largely used. It has excellent covering power, dries quickly, withstands weather well, and is first-rate for coating iron pipes, washing tanks, etc. Also, the paint has the peculiar property of rendering objects visible in the dim light of the dark room. Splendid, too, for rough wood frames, as the coating dries with a pleasing matt-silver lustre.

Mr. Merritt stated he made this paint by dissolving a stripped 5 by 4 Eastman portrait film in 2 ozs. of amyl acetate, adding powdered aluminium q.s. The paints stood almost up to red heat.

Berlin black has not the resisting properties of aluminium paint, but possesses many good qualities, and is cheap. Covers well, dries rapidly, and as a base for copal varnish gives a capital enamel effect. On iron work a charming egg shell finish is obtained. An accidental application of the black to the table cloth by Mr. Jobling drew from the secretary an adverse opinion as to its suitability for this purpose.

Bath enamel in photographic practice is useful for coating developing dishes. He had found two or three coats will withstand strongly alkaline developers.

Black Japan differs from Berlin black in containing a soluble bitumen instead of fine black powder in suspension. On metal it dries with a surface like glass and adheres well. Excellent for dark-lamps and projection lanterns as it will withstand considerable heat. The lecturer said he had known solder run down under-

neath it. When first heated the burnt smell is not attractive, but it soon wears off

For a dark walnut stain for wood, dilute the Japan with an equal bulk of turpentine. So diluted is ideal for picture frames and staining floors, as the solution penetrates well into the wood without raising the grain. For "fumed" oak the mixture is slopped on anyhow, allowed to remain from 5 to 10 minutes, according to temperature and hardness of the wood, and then wiped off with a rag so far as possible.

For thick celluloid varnish, dissolve 15 grains of celluloid clippings in one ounce of amyl acetate. Beyond 15 grains the varnish gets too thick to use conveniently. A 10-grain solution is a more useful strength. The formula in the B. J. Almanac, including acetone, had not worked well in his hands as it dried matt. Brushes are best washed in acetone, followed by methylated spirits. The addition of a little oil of lavender renders the smell less objectionable. "Nothing like the stink," confirmed Mr. Sellors after comparative nasal tests.

Mr. Purkis said the matt surface on drying was probably due to the use of commercial acetone. This can be avoided by employing the anhydrous acetone, which, however, is expensive.

Mr. Wratten mentioned the adaptability of thin celluloid varnish to coating surface silvered mirrors to preserve their lustre. Mr. Hibbert pointed out that if the varnish is too thin diffraction colours form. Dealing with the limit of 15 grains to the ounce, he said that the addition of acetone and sulphuric ether permitted more celluloid to be dissolved for equal viscosity.

For black celluloid varnish, dissolve 5 grains of "spirit black" powder (usual trade term) in 2 ozs. of clear celluloid varnish. Two or more coatings are necessary, those following the first coating to be applied quickly.

For the finest finish, copal varnish is compulsory, and it is very false economy to buy any but the best. The paint or enamel to be treated is rubbed down with pumice powder on moistened felt, and the varnish applied with a flat hog's-hair brush. For super-polish the felt is employed dry. If necessary, the varnish can be thinned with American (not Russian) turpentine.

Shellac varnish is very useful in photographic practice as it has no action on dry plates or sensitive papers. A normal solution contains 20 per cent. of orange shellac flakes in methylated spirits. Dilute with equal bulk of spirit for use as a lacquer. Mixed with ivory black (many recommend vegetable black) the normal solution affords a good dead black. A glossy black is secured by mixing one part of "spirit black" powder in 100 parts of the varnish—handy for touching up small metal parts. Shellac varnishes are unaffected by petrol or benzol.

A formula for white shellac varnish is :—

White shellac, crushed and dried	1 oz.
Sandarac	1 oz.
Venice turpentine	1 oz.
Methylated spirits	6 ozs.

For negative varnish, dilute with equal bulk of spirit and flow on warmed negative.

Mr. Jobling said he was able to publish for the first time an old and well-tried recipe for rough hands and faces, which he called the 'maiden's blush." It is as follows :—Powdered gum tragacanth, 1 dram; zinc oxide (pure), 1 oz.; liquid cochineal, 40 minims (this is the "maiden's blush" part); glycerine, 4 ozs.; oil of lavender, 20 minims; water, 7 ozs.

Mix the gum with a little of the glycerine into a smooth paste, and then add the oxide with more glycerine, incorporating thoroughly before adding the rest of the ingredients. Apply sparingly after washing.

An attempt by Mr. Jobling to beautify Mr. Sellors with this elegant cosmetic was successfully repulsed. A contest then sprang up between them as to the rival merits of cork lino and linoleum as a waterproof table covering. On the authority of each in turn it was interesting to learn that the other was past praying for in the matter of intelligence. A most hearty vote of thanks was accorded Mr. Jobling, and well he deserved it.

Edinburgh Society of Professional Photographers.—Mr. Lawrence, of Messrs. Kodak, Ltd., delivered a most instructive lecture on Tuesday in last week to an audience of over seventy people, professional photographers, in Edinburgh, Perth, Kelso, Dundee, Bridge-of-Allan, and elsewhere. The lecturer spoke on Eastman Portrait Films, and maintained the superiority of that film over glass plates. He stated that the opposition to the change from glass plates to the film was often due to ignorance and the superseding of old methods more than to anything else, and only required some acquaintance with the actual results of the film to turn it into appreciation. He referred not only to the saving of labour and costs, but also to the finer quality of the work obtained from the use of the film instead of glass plates. In speaking on the subject of spot lighting, or subsidiary lighting, as he preferred to call it, Mr. Lawrence advocated the use of restraint in subsidiary lighting and deprecated its use towards the development of "freakish" photography. The lecturer exposed several films and gave demonstrations showing the better results to be obtained from the subsidiary lighting and how it should be used. He also referred to the diffusion discs, which he said could be used to great advantage by photographers. At the conclusion of the lecture Mr. Lawrence received a very hearty vote of thanks, and the thanks of the meeting were also conveyed to Mr. J. Campbell Harper for the use of his studio for the lecture.

News and Notes.

Ensign Photographic Diary.—This handy little book, measuring only 3½ ins. by 2 ins., has been issued by Messrs. Houghtons, Ltd., of 88-89, High Holborn, W.C.1. Much useful information, together with several pages of handy tables, is included, and there is ample space for the recording of exposures. A diary section and cash pages with an ingenious calendar covering three years are also features. The diary is priced at 1s., and is obtainable from all the usual dealers.

Ensign Indoor Competition.—With a view to encouraging amateur photography during the winter months, Messrs. Houghtons, Ltd., are offering £50 in prizes for the best photograph taken in the home from negatives made with Ensign plate or film cameras. The first prize is £25. An attractive window bill has been issued to dealers, and supplies of it, together with counter leaflets and entry forms, may be obtained on application. The competition closes on December 30.

Summer Time to End.—The Home Secretary gives notice that Summer Time will cease and normal time will be restored at 3 a.m. (Summer Time) in the morning of Sunday next, October 8, when the clock will be put back to 2 a.m. The hour 2-3 a.m. Summer Time will thus be followed by the hour 2-3 a.m. Greenwich Time. All railway clocks and clocks in post-offices and Government establishments will be put back one hour, and the Government requests the public to put back the time of all clocks and watches by one hour during the night of Saturday-Sunday.

Portraits in a Hurry.—A writer in the "Yorkshire Observer" deals in a humorous manner with the taking of portraits for passports. "Quite a brisk business is being done," he writes, "Briskness, indeed, characterises the affair throughout. There is no time for nice posing, or for summoning up one's most winning smile. It is a grim, business-like transaction from beginning to end. One pays one's money—half-a-crown for six—and one has no choice. 'Keep quite still,' rasps out the photographer—like a company sergeant-major—'look straight at the lens!' Click, 'Thank you very much. Call to-morrow at two.' It is an object-lesson in precision. If only all photographs could be taken like that! How do they come out? Well, if the scrutinising officials can bear the shock, the victims can. And what does it matter, so long as one gets abroad?"

Autumn and Winter Photography.—A 48-page booklet entitled "Autumn and Winter Photography" and written by Mr. W. L. F. Wastell, has been issued by Messrs. Houghtons for sale at the price of 3d. It describes a large number of the accessories with the aid of which the amateur worker may conveniently add to his enjoyment during the winter months. Mr. Wastell discourses interestingly on these many specialties, turning from the storage of negatives to the use of flashlight, and so on, and nevertheless contriving to give a number of practical hints. The booklet is well illustrated, and is supplied to dealers in lots ranging from 100 to 1,000 copies with the dealer's imprint on the front cover at prices from 15s. to £5 5s. On the last page is described a bisecting rule for the central mounting of prints, which appears to be identical in principle with that which was the subject of an article contributed to our pages by Mr. Vivian Jobling on October 24, 1919.

COOKE LENSES.—Messrs. Taylor, Taylor and Hobson, 74, Newman Street, London, W.1, have issued a new catalogue of Cooke lenses, which is a good deal more than a mere price list, since it contains a number of pages of hints on the preservation of lenses, causes of defective definition due to the camera, and some notes (quoted) on depth of focus. The latter, it must be pointed out, are a very partial treatment of this question, and, in view of the fact that in much photography depth depends solely on the actual diameter of the diaphragm, and has nothing to do with the focal length of the lens, it must be somewhat confusing to the optically uninformed amateur to be told that the hyperfocal distance depends entirely on the focal length of the lens. The subject is further confused by calling the hyperfocal distance the "infinity point," a term which must surely offend even those with a crude sense of the fitness of words. However, Messrs. Taylor, Taylor and Hobson's own particulars of the various types of Cooke lens which they catalogue do in fact correct any misconceptions which may arise from these special notes. The list is one which the would-be possessor of a lens of the highest class should certainly possess. It is obtainable free on application.

LOW-STRENGTH HYPO.—Mr. W. G. F. Woodcock, general manager of the Association of British Chemical Manufacturers, writes:—It has come to the knowledge of the Council of the Association of British Chemical Manufacturers, that, following the decision of the Referee in the recent case under the Safeguarding of Industries Act, several parcels of hyposulphite of soda "pea" crystals have been imported into U.K. ports, which are of lower percentage than usual in respect of crystallised hyposulphite of soda. These low strength "pea" crystals of foreign origin will no doubt find their way on to the market, and so into the hands of consumers for photographic purposes, who will thus be receiving hyposulphite of soda of a lower test than that to which they have previously been accustomed. In bringing this matter under the notice of buyers of hyposulphite of soda for photographic purposes, this Association desires to add that ample supplies are available of hyposulphite of soda of *British* manufacture, of the highest possible quality, and of high test. It, therefore, urges buyers when making purchases, to stipulate for a British-made product. If any buyer should have difficulty in obtaining supplies of a British make, and will communicate with this Association, full particulars will immediately be furnished as to where supplies may be obtained.

PHOTOGRAPHIC SENSITOMETRY AND TESTING.—The Washington Government Printing Office has issued No. 439 of the Scientific Papers of the Bureau of Standards on the "Sensitometry of Photographic Emulsions and a Survey of the Characteristics of Plates and Films of American Manufacture," by Raymond Davis and F. M. Walters, Jun. For several years the Bureau of Standards has made measurements of the characteristics of photographic light-sensitive materials, aiming at uniformity in the standardisation of methods, so that the results by various workers may be directly comparable. The present paper (according to a notice in "Nature") gives details of the principles involved in photographic sensitometry and testing generally as introduced by Hurter and Driffield and published over and over again during the last thirty years. Perhaps it is desirable to restate them to render the paper more complete. The methods of the Bureau are more original. Their light-source is a 6 to 8 volt Mazda C automobile-headlight with a special blue glass filter, giving 2.73 candle-power and the colour of average yearly noon sunlight at the latitude of Washington. The principal other deviation from H. and D. methods is that the Bureau of Standards defines the speed of a plate as 10 divided by the inertia, instead of .34 divided by the inertia as adopted by Hurter and Driffield to fit in with their actinometer. For colour sensitometry a replica grating is used with a slit 2 ins. long, and the exposure is graduated by a disc with suitably curved apertures that is rotated close in front of the slit. The methods of making other tests are fully described. Appended are 86 charts, each dealing with a single plate and giving three characteristic curves representing the result of development for 3, 6 and 12 minutes respectively, a contrast development curve, a fog contrast curve, the fog being exclusive of the glass and gelatine, a spectrogram showing colour sensitiveness, exposure factors for several colour filters, speed, extent of the straight part of the characteristic curve, and the resolving power estimated by a standardised method. Only sensitive materials made in the United States, and practically all of these, are discussed

PHOTOGRAPHERS AND APPRENTICES.

To the Editors.

Gentlemen,—Our attention has been drawn to a statement on the back of the current prospectus of our evening classes in photography which may be read to imply a sweeping condemnation of professional photographers in their dealings with apprentices.

The unfortunate misplacement of a comma has converted a statement of the fact that *some* photographers do take undue advantage of the apprentices in their service, into one that may be read to mean that *all* photographers do so.

Obviously this was never our intention, and we ask you, therefore, to publish this disclaimer in fairness to the profession.—Yours faithfully, on behalf of the Polytechnic School of Photography,

ALBERT J. LYNDON,
Head of Department.

School of Photography,
309, Regent Street, W.1., September 28.

THE 1923 P.P.A. CONGRESS.

To the Editors.

Gentlemen,—The number of members registered at this year's Congress of the P.P.A. is reported to be 292, out of a membership of over 1,000. This, after the special booming this Congress has had, cannot be considered satisfactory, even after allowing for the effects of the slump in trade; and I think the poor attendance was due to the fact that September is a most unsuitable month for a professional photographers' congress. In the past I have been a regular attendant, usually staying in town for the full programme, but this year to my great regret I was unable to be present, and I feel sure I was one among many who found it impossible to leave their businesses at this time of the year.

For a number of reasons, such as the return from the holidays, children going back to school, the commencement of the Christmas trade, etc., a revival of trade takes place every year in September in the studios of the ordinary provincial photographer. The present bad year even has been no exception to this rule.

In my own studio I did more business in the week before the Congress than in any week in the preceding five months, and to leave one's business for several days at such a time, even for a congress, is both difficult and unwise. There is no need to point out the unsuitability of September for the seaside photographer, but it needs emphasis that the busy season for the majority of inland provincial photographers is from September to Christmas.

And now, gentlemen, it seems probable next year will again see a September Congress. No protest has been made; no protest will be made, for we are an undemonstrative lot! We shall again be unable to go. But that is not for our own welfare, or the welfare of the Association. The duty of the Council is plain. Before a September congress is again decided upon, a referendum should be taken through the post of all the members of the Association, asking them to state the month in which it would be most convenient for them to attend the Congress. A £5 note would cover the cost of this; all interested would vote on such a vital matter to them, and the question settled once and for all. The Council are out of touch with the ordinary member in this matter, but as business men they would see the advantages that would accrue from carrying out the wishes of the majority as recorded in the vote. My own personal opinion is that such a referendum would show a large majority for a month in spring, either March, April, or May.

One other point. A large number of professional photographers are dealers nowadays, and when the Congress and the Photographic Fair are held simultaneously (not necessarily in the same building) they benefit by the one journey to town serving for both functions. This must tend to increase the attendance at the Congress.—Yours faithfully,

JAMES SPEIGHT.

The Studio,
Sutton Coldfield, Birmingham.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

J. W.—Ordinary blacklead or stumping crayon is the material used for backgrounds on negatives. It is applied with paper or leather stumps. A *very soft* lead pencil may be used for fine details. You would probably do better if you got a "Billdup" outfit, as you can judge better what you are doing than with matt varnish.

B. P.—(1) Your trouble is probably caused by the light being too far from the condenser. Put the lamp up to, say, 6 inches from the condenser, and note if you get a better covering power using the 7½-inch or 8½-inch focus lens. We should advise that the condenser be altered back to its original spacing, and a ground glass diffuser used between it and the light. (2) The system for carrying a large number of plates is the Mackenzie-Wishart, in which the plates are carried in loose envelopes. The envelopes are quite light-tight, and are very light in weight.

R. B.—Your trouble appears to be due to the small amount of light you have available. The three 1,000 c.p. lamps you have on the right-hand side of your studio should be altered to two of 2,000 c.p. each, and the third one replaced by a standard lamp of 3,000 c.p. This could be moved about the studio and placed in any position as required. On the left side the light should be increased to 2,000 c.p., and the lamp so fitted as to allow of its use on the floor level if necessary. We should also suggest that you have a raised platform for your sitters, say 1 ft. from floor, to enable you to get a slightly lower camera level, your present level appearing too high. Diffusers should be provided for the lamps, and a large white moveable reflector placed near the door leading to the studio from the front shop. You do not seem to be getting good covering power with your lens, the feet of your sitters appearing other than sharp. The extra light may allow you to stop down a little and so perhaps correct this.

R. N.—We referred your query to Mr. R. P. Rudd, the author of the article, who replies as follows:—The "H" type is one of the two kinds of reflectors supplied by Messrs. W. J. Bartholomew & Co., 40, Gerrard Street, London, W.1., and which they recommend for use in small studios. Mainly, I use the reflected light from the angle formed by the screen (J) and the wall (K) and the corner of the ceiling, but I attempt and secure any form of lighting required at will simply by moving the lamp and reflector to the desired position. When "in situ" the distance required from lamp to secondary reflecting surface can easily be judged, care being taken that the Barkay reflector be properly focussed with the light from the half-watt 1,500 c.p. lamp. I use various distances from 18 inches up to 3 feet away from secondary reflecting surface, but there is no hard and fast rule. I alter it to secure the best lighting in the subject of the moment. Sometimes it is up in the corner near the ceiling, at other times down to within 4 feet of the floor for small children.

G. S.—Under the Electric Lighting Acts, both supply corporations and municipal authorities are given very considerable powers, and as the recent case of the Westminster company ("B. J.," May 26, 1922) showed, it is quite open for a company or undertaking to charge anything they like for current up to a certain maximum; that is to say, they need not charge everybody the same power rate, even if they admit that they are entitled to have current at a power rate. But what they are usually prevented from doing is the showing of undue preference between different consumers. We advise you to find out, if you can, consumers who are getting the power rate and are using the current pretty much in the same way that you are as regards total amount and intermittency of use. Never mind whether they are photographers or not. You aim must be to show that one consumer is being given preference over another, and if you can show that you stand a pretty good chance of compelling the people to supply you at the most advantageous power rate. You should look through the judgment in the Westminster case, and the article which we wrote upon it, as already referred to above.

K. W.—We certainly agree with you that it is best to rely entirely upon electricity, as your windows are too small to have much effect. The lamps you mention are quite good, but we should advise you to have separate diffusers on small stands. We think the candle power of your lamps should also be increased to allow of the short exposures necessary for children, and would suggest that one, two and three be 2,000 c.p. each and four and five 3,000 each. One hanging indirect pendant in about the centre of the studio with a lamp of 2,000 c.p. would be a great help. Your floor could be covered with felt, which is of smoother surface than carpet, and would take up the inequalities of the floor boards. Lamps 4 and 5 should be on standards, as the General Electric Company's No. F.A.6,201, and provided with focussing resistance, which allow of over-running the lamps. The lamps would be of a lower voltage than your supply, and would only be overrun during the actual exposure. Small separate diffusers should be supplied for these, while one larger diffusing screen would do for lamps one, two and three. The booklet supplied by the General Electric Co., Ltd., Magnet House, Kingsway, London, W.C.2, on studio lighting, would be of interest to you.

S. B.—The cameras for while-you-wait ferrotype or card portraits are of rather an elaborate type, as they contain a changing device for bringing, frequently, 50 cards or plates successively into position for exposure and also provide for developing in daylight. As some of the cameras are not expensive, we think your best course would be to apply to Messrs. Jonathan Fallowfield, Ltd., 146, Charing Cross Road, London, W.C.2, who supply all makes on the market. An ordinary lens is used. The following is a formula for the combined developing and fixing bath:—

Water, to make	40 ozs. fluid.
Hydroquinone	½ oz.
Soda sulphite	4 ozs.
Soda carbonate	4 ozs.
Hypo.	8 ozs.
Liq. ammonia .880	2 fl. ozs.

Addition of more ammonia to the developer gives more vigour. The plates develop (and partly fix) in two or three minutes. They can then be examined in daylight and fixed in plain hypo. You really make a negative by the process, but as it is on a black surface, and as the developer produces a whitish coloured image, the effect obtained is that of a positive.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3258. Vol. LXIX. FRIDAY, OCTOBER 13, 1922. Price Fourpence.

Contents.

SUMMARY.

A leading article is recommended to the study of employers and assistants in photographic establishments for the sake of the general sense which it aims to convey of the legal relations which exist between master and servant under common law. The present series of notes, dealing chiefly with the establishment of this relationship of employer and employed, will be followed by another in which the writer will consider more particularly the legal aspect of conditions of service and the severance of the relationship. (P. 614.)

At a recent congress of the Photographers' Association of America Mr. H. Wills read a paper containing a wealth of practical information on the making of good portrait negatives. His hints ranged from the provision of screening and reflecting appliances in the studio to efficient arrangements in the dark-room and in the mixing of photographic solutions. (P. 617.)

In the present issue Mr. J. Effel resumes his talks on the work of a portraitist in the studio, and has some good advice to give on the part which a sense of psychology should play in photographic portraiture. (P. 615.)

Several correspondents urge upon the Professional Photographers' Association the desirability of holding next year's Congress at the same time as the Photographic Fair. (P. 627.)

Renewals of half-watt lamps are an advisable precaution at the present time of year, and may be done at less expense than hitherto. (P. 613.)

Some hints on the lighting of sitters against white backgrounds in the making of portraits in the shadow-profile style are given by a contributor in an article on page 620.

A suggestion in the manipulation of studio blinds and hints on the copying of line drawings are given in contributors to "Assistants' Notes." (P. 621.)

At the Royal Photographic Society on Tuesday evening last Dr. Reginald S. Clay delivered the twenty-fifth Traill Taylor Memorial lecture, where he made a highly condensed review of the development of the photographic lens. (P. 624.)

The Photographic Golfing Society had a most enjoyable autumn meeting at West Runton, Norfolk, last week. A group of those who attended, among them many leading members of the photographic trade, is reproduced on page 626.

The Northern exhibition is to be held in the City Art Gallery, Manchester, from February 5 to March 3. (P. 626.)

Although often attributed to the late Major-General James Waterhouse, the form of lens stop long used under this name was the invention of a John Waterhouse, who published a description of it in 1858. (P. 613.)

EX CATHEDRA.

The Life of Half-Watt Lamps.

The falling leaves give us warning that the artificial light season is again upon us, and that it is well to see that the installation which has done good service in the past is given a fair chance for the immediate future. Much will depend upon the amount of work which has been exacted from the lamps, but if they have been in constant use it is very probable that a considerable loss of actinic power has occurred. Even if indistinguishable to the eye, a slight deposit on the globe will cause a yellowness of the light, and this can only be detected by comparison with a fresh bulb. A test may be made with an ordinary Watkins meter, or, what is more satisfactory, comparative exposures may be given with a fresh and a used bulb respectively. It is very satisfactory to note that a considerable reduction has just been made in the price of half-watt lamps, so that it will not be a serious matter to provide the necessary renewals. When a number of lamps are in use it is a good plan to change them round from time to time, as there are usually two or three which get more work than the others.

* * *

The Waterhouse Stop.

It would appear that the name of the lately deceased Major-General Waterhouse is associated in the minds of many people with the particular but now largely obsolete pattern of lens diaphragm which for half a century and more went by the name of "Waterhouse." As a matter of fact, however, General Waterhouse had nothing to do with it. Those who take an interest in the origin of the appliances or processes of photography may be invited to turn to the "Journal" of what is now the Royal Photographic Society for the year 1857-8 on page 258 of which they will find the first description of this form of diaphragm in a letter written by John Waterhouse, of Wellhead, Halifax, on July 1, 1858. The writer begins by pointing out the advantage of inserting a diaphragm between the lenses of a portrait objective instead of applying a stop to the front of the lens as had been hitherto done. He proceeds to describe the cutting of a slit in the lens' tube and the insertion therein of a thin metal plate in which is a circular aperture of any required size. Except for the small projecting piece, which in later years was marked with the F. No., this original Waterhouse stop was identical with those which throughout a long period of years were fitted to lenses, until the greater convenience of the iris diaphragm caused them to fall into disuse. We are afraid we must plead ignorance of any further details of the life of this inventor of a universally employed photographic accessory. Perhaps some of our readers of the older generation can tell us something of John Waterhouse. In this connection it is interesting to note that in the library of the Patent Office is a volume of MS. notes and cuttings collected by

"J. W." prior to the year 1859. It is possible—and we have the idea that this view is taken by the Patent Office librarians—that this "J. W." is identical with the John Waterhouse who gave his name to the diaphragm.

* * *

Vertical Enlargers. The ease with which the self-focussing vertical enlargers can be manipulated must cause many would-be users to look with envy on the full-size installations of this pattern. While smaller and less expensive models are now available, including a condenser pattern by Messrs. Houghtons, there are, however, ways by which many of the advantages of a vertical enlarger may be secured by those who possess lanterns of the ordinary pattern. If fitted with a condenser, the latter should be retained, but as a rule it is better to discard the clumsy lamp house and to instal a light tin or iron box to carry the light, which may be incandescent, electric, half-watt, if possible, or gas, the inverted mantle being excellent. A sheet of finely-ground glass should be placed close to the condenser. This will almost obviate the necessity for adjusting the light. A couple of grooved runners should be fixed to the wall, and between these a frame to carry the lantern (which will, of course, have the lens pointing down) at the distance of about one foot from the wall. The whole is now suspended by cords and weights similar to a window sash. A table beneath completes the outfit. Focussing may be simplified by fixing a scale on one of the runners, which will give the total distance between negative and paper for various degrees of enlargement. The negative being set opposite to one of these, and focussing done in the ordinary way, the image will be the desired size.

SOME NOTES ON THE LAW OF MASTER AND SERVANT.—I.

With the possible exception of matrimony there is no relation more common than that of master or servant, nor is there one which in its legal bearings is less generally understood. Since questions depending on this well-defined legal relation constantly arise in the dealings of photographic assistants with their employers, it may be of advantage to attempt a bird's-eye view, so to speak, of the law of the subject. Within the limits of an article of this nature it is, of course, almost impossible to deal with particular cases or problems, but it has been the writer's aim to convey the general sense by which a lawyer is guided in forming an opinion of any concrete dispute. In these democratic days he should apologise in advance for the constant use of such undemocratic expressions as "master" and "servant." He speaks, however, in the language of the law, which delights in such crude but simple terms. After all, the words are, perhaps, less likely to lead to confusion in the minds of the reader (and of the compositor) than their more modern counterparts "employer" and "employee."

To arrive at a due understanding of the important relationship of master and servant, it is, perhaps, advisable to distinguish it from the somewhat similar relationship existing between a principal and his agent, for it by no means follows that the legal principles which govern the relations between a master and his servant are equally applicable to principal and agent. The true distinction between the two cases is that a principal merely directs what work is to be performed by his agent, but has no control over the method by which the work is done, while a master not only orders the work to be done, but has the right to direct how it shall be done.

For instance, a London photographer, who visits a country town for professional purposes once a week, and who arranges that a local stationer shall book orders for him on a commission basis and expend a specified sum provided by the photographer in advertisements, is a principal in the transaction, and the stationer, who is left a free hand as to the methods to be employed in securing orders, is his agent. If, however, the photographer opens a studio in the country town and places a salaried manager in charge of it, the relation between him and the manager is that of master and servant. All such employees as studio operators, printers or receptionists are "servants" within the legal meaning of that term, and their employment is governed by the principles which this article endeavours to elucidate.

Even where it is clear that the relationship is not that of principal and agent it does not always follow that the position of the parties is that of master and servant, since, in some cases, and particularly those in which the remuneration varies with the profits of the business, there may be some evidence of a partnership. There is no very satisfactory general test which can be applied to such a case, the precise legal relationship of the parties depending upon their intention as gathered from their acts and all the surrounding circumstances. It is provided by the Partnership Act, 1890, that the receipt by a person of a share of the profits of a business is *prima facie* evidence of the existence of a partnership between him and the other persons who share the profits, but that the remuneration of a servant by giving him a share of the profits does not by itself make him a partner. It follows then that if, apart from the fact of an employee receiving a share of the profits, he would be only a servant, something more than the payment to him of such share (for example, the acquiescence of the proprietor of the business in his engaging or dismissing servants or entering into business transactions) is necessary to establish evidence of a partnership, while the fact of his receiving a fixed salary in addition to a share of the profits is strong evidence against the existence of a partnership. The payment to a person employed in a business of a commission on business introduced by him would not in itself constitute him a partner.

The relationship of master and servant is created with the greatest ease. With the one exception mentioned below, no formality is necessary; a mere agreement (either verbal or written) by one person to employ and by the other person to be employed is sufficient and, even in the absence of an express agreement, the law can imply the relationship, from the fact that some person is found to be working for another with the latter's consent. In one case, however, namely, where the relationship is intended to continue for more than one year from the date of its creation, an Act of Parliament passed in the reign of Charles II., and known as the Statute of Frauds (a measure designed for the prevention of fraud which was once stigmatised by a very eminent Judicial authority as being more conducive to fraudulent practices than any other legislative enactment) requires it to be evidenced by a written document signed by the party whom it is sought to hold to the agreement. For instance, an agreement for the employment of a servant for two years, or an agreement made in January for the employment of a servant for six months from the 1st October (which will consequently continue for more than one year from the date in January on which it is entered into) will not be binding on any person who has not signed a written memorandum of it, but if one of the parties signs and the other does not (as if, for instance, an offer of employment contained in a letter written by the employer is accepted by the employee verbally), the agreement may be enforced against the

one who signs but not against the other. The memorandum of the agreement need not be a formal document, so long as it contains all the terms, and it may consist of a letter or a series of letters. The memorandum should either be signed across a sixpenny adhesive stamp or presented at Somerset House for stamping within fourteen days after signature, or, in the case of the memorandum consisting of a series of letters, within fourteen days of the date of the last of such letters. The absence of a stamp does not render the agreement invalid as is popularly supposed. The only effect of failure to stamp a document is that in any legal proceedings arising out of it the document cannot be given in evidence without paying the proper stamp duty and a penalty, which is usually £10.

Whether the agreement for employment is written or verbal the law will always read into it any well-established general custom of the business to which it relates, unless the application of that custom is expressly excluded by the terms of the agreement.

Even an agreement with an infant (that is, a person under the age of 21 years) will be binding on him if it is for his benefit. The question whether an agreement is for an infant's benefit is one of fact depending on the particular circumstances of each case, but, speaking generally, it may be said that if an infant employee agrees to give his services in return for a fair rate of remuneration the agreement will be binding on him, and not liable to be repudiated by him under the general principle that an infant is without legal capacity to enter into contracts.

In common with most other human enterprises a contract of service is more easily entered into than terminated. In the ordinary course the employment is deemed to be for a year, and, if it continues beyond the end of the first year, to run from year to year, although the wages may be paid at more frequent intervals than a year, and in such a case the employment can only be terminated by either party at the end of a year of service, in the absence of some express agreement or well-established custom of the trade to the contrary. If, however, the wages are expressed to be so much per week or per month or per other period less than a year, this circumstance is sufficient to take the case out of the ordinary rule, and the employment may then be terminated at any time by reasonable notice on either side. Numerous decisions (some of them by no means easy to reconcile) have been given by the Courts on the question of what constitutes reasonable notice, and from these there may be deduced the sound working rule that persons in responsible positions, such as managers, must receive or give not less than three months' notice, while one month will suffice in the case of assistants or clerks. The notice need not be so timed as to expire at the end of a calendar month, and, in the case of a servant whose employment can be terminated by a week's notice, the notice can be given on any day of the working week. Questions sometimes arise as to what notice is necessary where a servant is engaged on a month's or four weeks' trial, the salary being paid weekly. It is clear that in such a case the engagement is for a definite period of one month or four weeks only (as the case may be), and at the end of that period may be terminated by either side without notice. If, however, the employment continues beyond the original period, it can then only be terminated by such notice as, having regard to the position occupied by the employee, is reasonable or is required by the custom of the trade in which the employee is engaged.

Apart altogether from any question as to notice, a contract of service is terminated automatically by the death of either party or a dissolution of partnership if the employers are a firm. An Order of the Court for the winding-up of a Company also operates as a termination of the employment of its employees, although, curiously enough, the bankruptcy of a private employer does not have a similar effect. Some further notes on the circumstances which, in common law, justify the breaking of the contract and determine the conditions of service must be postponed to a later issue.

G. E. S.

WITH A PORTRAITIST IN THE STUDIO.

The reports of the P.P.A. Congress, Salon and R.P.S. Exhibitions having made large demands on our space during the past three weeks, the present series of chapters by Mr. J. Effel have unavoidably been interrupted. This week Mr. Effel resumes his place, and in the next paper of his will take accessories and backgrounds as his subject.

VIII.—THE PSYCHOLOGICAL ASPECT.

Psychology is a word very largely used nowadays, and invariably employed in a wrong sense. I mention this here because I wish to anticipate pedantic critics, who might fall foul of me for mis-use of the language. When I urge the importance of the psychological aspect, I mean that the student of portraiture should have a more than usual understanding of human nature, that he should know his own powers and his limitations, and should be quick to apprehend the likes and dislikes of the widely different individuals who patronise the portrait photographer. Briefly put, in this paper I use the word psychology to indicate the mental attitude of a photographer towards his clients, and of the clients towards the photographer, his methods and his work.

However we may argue the point, whether it pleases us or offends our vanity, we are to be classed with butchers, bakers, drapers, and other tradesmen in so far as we are all in business for profit, that we have goods to sell, that the better the quality of our goods and the more attractively they are displayed the greater will be our chances of success. Of course, no exact parallel can be drawn between photography and other sellers of commodities, for the photographer is in the unique position that he requires the active co-operation of his client in the production of his goods. One may not be in a good mood when the tailor is taking measurements, but that fact will not affect the ultimate fit of the garments, a hatter may be quite mad, yet make good hats; and who on earth would care a rap about the untidiness of the man who makes our boots? Attempt to classify the portrait photographer with other professions and businesses, and you will speedily find that all analogies break down. I know of no other calling, not even that of the portrait painter, where it is so essential that there should be something of psychological affinity between the two parties to ensure the happiest results. It is because the mood of the sitter counts for so much, and that mood is determined so largely by the moral effect produced by the artist, that I lay stress on the importance of the psychological consideration. We have heard a great deal about posing and lighting the body; I would talk to you now of posing and

lighting the mind. When you see more—in the psychical as well as the physical sense—you may actually photograph more.

Lest the impatient young photographer think I am going to counsel him to repeat words to the effect that every day his work gets better and better, I hasten to assure him that I am an essentially practical-minded person, and that the only "suggestion" I have faith in as a help to better business is that every day he should study his craft more and more.

A doctor does not rely upon his knowledge of the curative properties of drugs alone; the most successful lawyer is not necessarily the one with the most erudite knowledge of law; a knowledge of ailments, of their symptoms and proper treatment is, of course, taken for granted as being possessed by the general medical practitioner, the solicitor certainly knows the legal points which are obscure to the layman, yet I think I am well within the mark when I say that quite half of the

A Soulful Child.—This portrait is a capital illustration of numerous points touched on in this and previous articles. Everything is subordinate to the expression; it is a perfect example of a three-quarter view of the face. The direction of the eyes is dead right. Little light is used, and the small nose made to stand out. While there is hair in profusion, suggesting other treatment, the artist has purposely narrowed down the interest with the chiffon on the head. The student may see how stout or awkward figures could be so treated that the eye would be deceived about the outline. Note that the lighting is very simple, and that the fragile body is hidden with very full drapery.

work of the good doctor or lawyer is done by psychology, and the application of good common sense *minus* law or medicine.

Portrait photography from the show case to the reception room, to the dressing room and studio, from the advertising of goods, the selection and salesmanship, the manner and ability of the operator, is a calling where the psychological factor is of paramount importance. Meantime, I am only concerned with the studio part of the business. Let us consider what psychology has to do with producing better negatives.

When I say that the success of the studio worker is quite three parts brain work to one part technique, I mean a great deal. Mixing equal parts of sulphite and carbonate, boiling black prints in alum, hypo and dirt till they turn brown, leaving a hundred plates in a box containing standardised solution for twenty minutes, are not operations calling for much intellectual effort. In fact, nowadays, the production of negatives and prints of the "D. and P." order should merely be a case for the use of scales, thermometer, and a clock. Mark this point, that I am only writing for the assistant who is thoroughly conversant with judging exposures, and making negatives of good printing quality; with the scatter-brained photographer to whom every negative exposed sets him guessing, the man who sprinkles bromide (alleged 10 per cent. solution) lavishly, plays around with reducer and intensifier and "weighs" everything, from metol to hypo, in the same "chuck and chance it" way, I confess I can do nothing. Given the willing, able assistant (and I am convinced there are thousands capable of assimilating advanced tuition), the higher flights of portrait work will only be attained by working and thinking out things for himself. To make the photographer think, to make him realise that if he doesn't constantly mix brains with his formulæ he will get left in the struggle, are difficult enough tasks to set myself, but I not only hope to succeed, but to prove that the profession of portrait photographer is an intellectual one requiring at least as much mental effort as that of the writer or the actor.

I understand that it was the custom of a lady photographer who enjoyed a big vogue to ask her clients to visit her on a day previous to the appointment for the sitting. After a friendly chat over a cup of tea, the photographer reckoned that she had made progress with her client, and that the subsequent operations in the studio were greatly simplified by this preliminary interview. I do not doubt this contention for a moment, but those businesses must be very rare, nowadays, where the principal would have the leisure and the clients sufficient interest for this ritual. We live in an age where speed is a great consideration. I would be sadly lacking in psychology myself—to say nothing of humour—if I were to advise photographers generally to add hospitality and psychoanalysis to the other terrors popularly associated with a portrait studio.

But if a preliminary interview with a sitter is scarcely practical politics, the photographing successfully of a person one has never seen before is a task of extraordinary difficulty. I cannot think that Whistler would have given us a masterpiece of Carlyle had his medium been photography and the portrait taken in a few minutes on a busy Saturday afternoon. Yet that is how the majority of us have to work, and I submit very seriously that a man who "handles" thirty or forty clients daily, men, women, children, of all tempers and temperaments, and consistently produces work that pulls good orders with but a negligible number of resittings—I submit that he deserves to rank as a man of considerable professional skill. It rests with the individual photographer himself to maintain this dignity.

Charles Dickens, who was something of a psychologist, tells us somewhere that after knowing a man intimately for twenty years he was greatly surprised at an action of his which seemed quite foreign to his character. The great student of human nature was merely showing what a complex study the human mind is, yet photography is more exacting than novel-writing; mistakes are well-nigh irrevocable; there is more retouching and faking possible to the literary than to the photographic artist. What the trained observer failed to see in twenty years the portraitist is frequently asked to see in twenty seconds. Of course, it cannot be done. Surely, we have all had the disconcerting experience of taking negative after negative without quite satisfying ourselves, and then, when we had finished the sitting, of seeing the client posing and smiling delightfully? One cannot give a formula that will enable the earnest photographic worker to catch the self-conscious subject at what is literally the psychological moment. After all, one has to *see* a soul before one can photograph it; in what may be rightly called "portrait studies," qualities needed far more than art training and technical skill are insight, sympathy, and a profound knowledge of the joys and

sorrows of life. Look at that priceless gem, "Girl with a dead canary," by Greuze. Greater than the technique of the master is the heart of the artist. To the casual glance it may merely represent a child crying: in reality it is a study of a soul in pain. It is fortunate, maybe, that the photographing of souls has not yet become a craze. Why then waste time talking about it? For two sufficient reasons, the first being that I consider the rendering of "character" to be the highest achievement of the portraitist. But to the practical worker who has constantly to keep before him the question of profit, my second reason will have more weight. I merely urge that the portrait photographer should study psychology sufficiently to "sense" quickly what will appeal to his client. One may see a very vulgar soul, and yet not wish to photograph it, but certainly the vulgar one's clothes have to be taken to perfection. I said before that to *do* more the photographer must *see* more. I would now like to add that when he sees more he may want to *hide* more.

J. Effel.

(To be continued.)

SHORTENING THE ROUTE TO GOOD NEGATIVE MAKING.

[The Photographers' Association of America held their 40th annual Convention at Kansas City, Missouri, on May 1 to 6, 1922, under the presidency of Mr. G. L. Hostetler. The proceedings of this Convention are published in excellent style in book form running to 175 pages. Superbly printed, and with some excellent illustrations, the Association are to be congratulated on producing such a pleasing volume. Amongst many interesting lectures and demonstrations is one by Mr Harry Wills, of Rochester, New York, which, we think, will be of great use to our readers. The lecture, a somewhat abridged version of which appears below, consisted of practical hints on the various processes which enter into successful negative making. In particular, the dark-room practice suggested by Mr., Willa is a move in the right direction, for it is often in this branch of the work that improvement is most needed.]

Most of our troubles in making a negative begin in the studio, and I believe that many operators will agree with this statement. A great many photographers might insist that they do not sell the negative to their customer, but they sell the print. I insist that the negative is the foundation for the article which you are delivering to your customer, and if the foundation is weak, the structure cannot stand up. You may use all the schemes and all the business methods to get the people into your studio, but you must back up these methods with good photographs, otherwise your days of success in the photographic business are numbered. We are at a time to-day when we must make better photographs than we ever made before. You must begin with your negative, and for the most part that negative is made in your studio. If you are not getting negatives which yield satisfactory prints, you must analyse your working conditions as well as your ability to control your light, and find out the reason for your failures before you can hope to correct them. Three pieces of apparatus that I consider essential in any operating room for the convenience of putting any light under almost perfect

Fig. 1.

control, whether it be a skylight or an artificial light, are shown in fig. 1.

The little side screen is 36 inches wide and 7 feet high. There is an opaque shade on a spring roller, attached to the bottom of the frame, for raising and lowering at will. Attached at the top, over a small curtain rod, is a piece of black India linen, which slides backwards and forwards. There are times when one does not want to cut out all the sidelight, but simply soften or slightly diffuse it. By lowering the opaque shade, and drawing over the thin curtain from the top, you will be able to diffuse your light to almost any degree, or you can diffuse a small portion of the sidelight and allow the pure, unobstructed light to come in the other portion if required.

Fig. 2.

This little screen is very practical and inexpensive to manufacture yourself. After we have cut the side light down to where we want it, we have a head screen. It does not necessarily have to be this particular type of screen, but if the top light overbalances the side light, or is too broad on the forehead, you must have something to soften or point it up into balance with the side light, and it must be a screen of some kind—not too large—and easily adjusted. I

prefer the dark thin covering, as illustrated in the top of our side screen. The third piece of apparatus shown here for light-control is a reflector, which is very practical and easily manipulated. The dark side comes in very handy for cutting out the reflections from the floor which very frequently give trouble in eyeglasses. The top tilting effect on this reflector can be used to very good advantages for giving us a very slight illumination in our shadows, and yet turned at such an angle that it does not interfere with eyeglasses or reflect false lights into the eyes.

Fig. 2 represents two small black screens, which I consider, the handiest little screens in a studio, especially where spotlights and back-lights are being used. One screen is intended to be used in front or between the spotlight and the lens, so that the light cannot be seen in the lens. These screens are 24 inches wide, and 6½ feet. high, and are covered with black sateen. Sometimes two spotlights are used, and two screens are then essential. I have seen a great many fine negative possibilities spoiled by getting a flare of light into the lens. To arrive at the short cuts to good negative making we must simplify and make our working conditions in the studio easy and efficient. First, we must have a light of the right photographic quality and plenty of it. If we have too much light it is a very simple matter to cut down the volume. There is no excuse for not having plenty of the right kind of light at all times, for there are many artificial lighting devices at our command, which have proved to be very satisfactory.

Have the right kind of lenses to meet all your requirements, and do not try to photograph interiors, groups and large heads with the same lens. I want to dwell a moment on the importance of keeping lenses clean and ready for use at all times. It is very surprising to me to find throughout this country, so many dirty, neglected lenses in use every day. We cannot possibly expect to

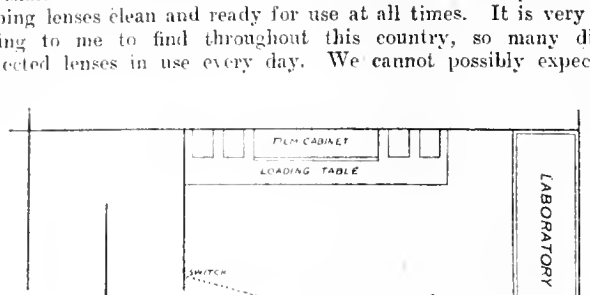

Fig. 3.

get clean, crisp, brilliant images with lenses that are covered with a scum. Our shutter and bulbs should be kept in working condition. If we have a shutter that does not work accurately and we cannot fix it, there is but one thing to do and that is to get a new one. It does not pay us to work with a shutter that does not open and close all the way every time.

A lens hood for the front of our lens is just as important as eye lashes are to protect our eyes from conflicting glaring rays of light. The lens is the eye which sees the picture, and if it does not see it clearly, we cannot expect to register it clearly on our film or plate. The camera and stand should be, at all times, in working condition and kept clean, inside as well as outside.

A presentable clean and practical working focussing cloth on the camera will add to the general appearance of your camera room, as well as backgrounds of different desirable tones, easy to manipulate, so that they do not require two people to handle. If chairs or other pieces of furniture are used, they should be of a practical type and kept in good condition and easy to handle. Your screens for light-control should be of a practical kind and should be kept in repair and be easy to manipulate. Convenience in the camera room: This reminds me of a demonstration I was called in to make a few weeks ago in a popular studio. Everything was working well except the camera stand, the cogs on the raising and lowering gear having been stripped. When we succeeded in getting the camera at the proper elevation, I was handed a large nail by the operator, who suggested that I slip it in between the cogs to hold the camera bed in position. It happened that I had been introduced as an expert operator to the lady who was posing for us, but before completing the work, I felt that I was anything but an expert operator, and that our lady subject thought we were a couple of cobblers. In other words, we had failed to make a favourable impression, because our apparatus was not working.

In regard to plate-holders, it is best to have enough filled to complete your sitting, without taking time to change, as much

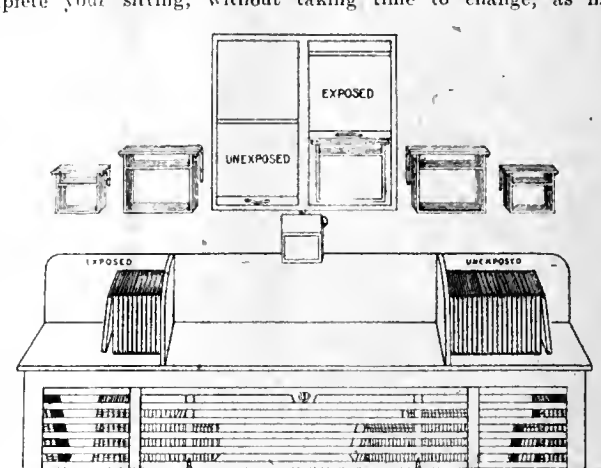

Fig. 4.

time is lost while the operator is in the dark-room changing his plates or films. It is also essential to have a rack on the side of your camera for keeping plate-holders within convenient reach. Another service which I consider very practical for taking care of the unexposed and exposed holders while working at the camera is a small table on rollers with compartments. This little table can be moved around with the camera within convenient reach of the operator, no matter which side of the camera he is working. In making the exposure, there is one rule nearly as old as photography itself, expose for the shadows and the high-lights will take care of themselves. Therefore, to be a successful operator you must learn to read the registering values of your shadows. The high-speed plate or film does not contain the same line of gradation as that of the medium speed product. Therefore, the high-speed plate should be developed to a greater density than those of lesser speed, otherwise you will be inclined to get flat, thin negatives.

We will now take the dark-room work as briefly as possible and endeavour to show by proper equipment and conveniences that we can also make short-cuts and sure-cuts in the developing of the negative. Fig. 3 shows a suggested floor plan of a practical dark-room, containing chemical cabinet, developing bench and sink, loading table, and drying cabinet. A dark-room should be a pleasant and convenient room to work in, and there should be plenty of ventilation in this room. It is just as essential to have good ventilation for the good of the sensitive gelatine products, as it is for your good health. The walls of this dark-room do not have to be black or dark. They can be white if no white light enters

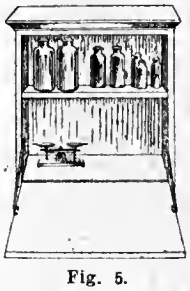

Fig. 5.

the room. Fig. 4 shows the loading table, which, I think, is very practical. It has a place for exposed and unexposed plate-holders, and has two cabinets immediately above the centre of the table for exposed and unexposed plates. In the centre is a small safe-light to assist in loading the plates or film. On either side of the centre cabinet are racks for plate or film developing hangers to keep them off the table and off the floor. Underneath is a little

lattice door to enable you to see the condition of your plate or film stock, and a shelf for keeping surplus holders.

Fig. 5 represents the chemical cabinet which is very convenient to have in a dark-room. The door opens down from the top, and when opened forms a shelf on which to weigh out your chemicals. When finished push everything back and close the door. This eliminates all possibility of chemical dust in the room, and in many cases saves a multitude of troubles. A developing bench and sink is illustrated in fig. 6. On the left-hand side we have a developing

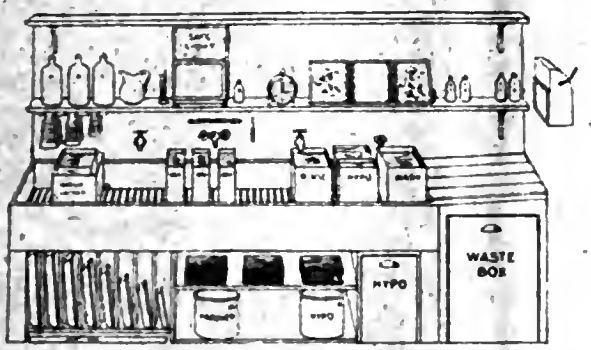

Fig. 6.

tank in a water jacket made of galvanised iron. There should be a two-inch space all round the developing tank. In cold weather this can be filled with warm water to raise the temperature, and in hot weather with ice or cold water to reduce the temperature. In the centre are three developing tanks, which contain solutions of varying strengths. To the right is a rinsing tank with water running into it. Next we have two hypo-baths. When the negative comes out of the rinsing tank, it should go into the first hypo bath. When that bath is full it should by all means be taken over to No. 2, and then from there it should be removed to the washing-box. The importance of two hypo baths is that No. 1 bath receives all the water and alkali that remains in your negative and will very shortly weaken the No. 1 bath. For that reason, after a negative goes through No. 1 it should always be taken into No. 2 and left there for a sufficient length of time until it is thoroughly fixed. No. 2 bath is always a comparatively fresh bath, and the method for keeping it fresh is this: When No. 1 bath does not clear a negative in ten minutes throw it away, and put No. 2 bath in the position of No. 1. Then put a new bath in the position of No. 2. For the convenience of making this bath up quickly and keeping it up to standard, we have underneath the sink two jars; one of hardener made up according to formula and one of hypo also according to formula. Take the given amount of hypo and the given amount of hardener and we have a new bath in very short time. The principal importance of two fixing baths is the freedom from stain. A negative fixed in an over-worked bath, while it may appear clear, contains an invisible substance which soon becomes discoloured, sometimes unfortunately all over the negative and other times only in spots. One cannot put too much stress on the importance of properly fixing the negatives. If a negative is properly fixed it can be washed in circulating water for 15 minutes. Directly over the washing and fixing boxes is a negative comparator. This is very important to standardise the density of negatives. Sometimes the density varies to a very great degree, and, at the same time, the worker is confident that all are just the same density. In this comparator are put one negative of a dark ground and one of a light ground of the average density required to make the kind of prints you are accustomed to making. You can always tell when looking through the washed negatives, before hanging them up, just how far off is the density, or if in doubt, stop during development, fix out a negative and compare it. The centre compartment of this comparator is ground glass with light behind. When developing the average portrait plate or film, Wratten Safelight, Series 2, is quite practical for the very highest speed product, but if you are using panchromatic plates it is necessary to replace it with the Series 3, which is a green light. Panchromatic negatives should be developed by the time and temperature method, as it is very difficult even with a green light to judge the developing density. The green light is a convenience for handling the plates only. If the proper kind of lights are used, a dark-room should always be light enough to see all around it. Under the drain board we have a waste box for all waste papers, film and plate containers, also a hypo bin. At the extreme left we have racks for such trays that might be used for intensifying, reducing, etc.

Fig. 7 illustrates a drying box either for plates or for films. This box can be installed in the dark-room or in some other room convenient. It is 28 inches high, has a shelf in the centre, and is deep enough to take the drying racks. Sliding doors are practical for the reason that they can be opened at any section and negative racks put inside. The entire box can be covered with cheese cloth, or it can be made of compo board. If there is not too much dust flying around, I would prefer the cheese-cloth. There is an opening at one end for a fan which gives air circulation through the negatives, causing them to dry quickly, and free from grit or dirt. Sometimes it may be convenient to put the fan on the outside of the dark-room wall and bring the air from another room.

We now come to the different kinds of developer used for the making of the negative. We have pyro, the old stand-by, Elon and hydroquinone, and a number of others. Pyro, together with Elon, makes a very desirable developer. Elon has the action of a very soft developer, and, properly balanced with either pyro or hydroquinone, gives very pleasing effects, but remember that pyro and hydroquinone are the two contrast agents, and those agents, properly proportioned, with carbonate and sulphite, will give you a satisfactory reduction of the silver image, when used at the proper temperature. Pyro, Elon, or hydroquinone should be used at 65 degrees Fahr. If a developer containing hydroquinone and Elon is used at a temperature lower than 65 degrees, the action of the hydroquinone will be greatly reduced. The Elon, doing practically all the work, will give you a soft, weak negative. In using pyro-soda two images are made. One, known as the stain or pyro image, and the other the silver image. Therefore, in pyro developer it is essential that allowance is made for this stain in judging density. A negative that does not have this stain, such as an Elon-hydroquinone developed negative, must be carried further so that the high-lights do not grey over in the print. Sulphite of soda is included in this developer as a preservative and preventive of staining. It has the greatest affinity for oxygen of any of the chemicals that we are using. Therefore, it keeps the oxygen away from the pyro until the sulphite has been exhausted by the oxygen, and then the pyro will commence to discolour. Sulphite is your colour control. soda carbonate gives the detail and pyro the contrast. These three chemicals can be balanced to produce any desired type of negative. I have found that many localities require different balance of the chemicals used in developer. For instance, if alkali is found in the water it will be necessary to decrease the amount of carbonate used. If hard-water is the local condition, it is necessary to increase the amount of carbonate, but remember that when you increase the amount of carbonate it is also necessary to increase the amount of sulphite, I have also found water conditions that required more pyro. Sometimes, in addition, it was advisable to use a small quantity of Elon and hydroquinone in order to get the action required. In some places iron is very prevalent in the water, and it is then necessary to use more sulphite in order to keep down the stain. There is absolutely no excuse for getting a stained negative, or a negative of an undesirable colour, if you understand your local water conditions and the chemicals you are using. That, together with the proper hypo bath and sufficient

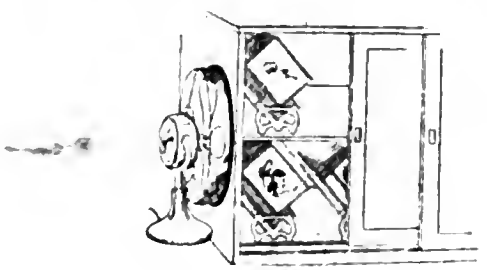

Fig. 7.

time for fixing, will prevent stains either with films or plates. There is positively no reason why films should stain any more readily than plates if the developers are balanced and the hypo baths are in good working condition.

At this point I want to mention the importance of pure chemicals. There is a vast difference between both the carbonate and sulphite of soda that is on the market to-day. The best of them are comparatively cheap, and it will pay you to buy such chemicals that carry a guarantee; chemicals that are tested and known to be pure,

are the cheapest investment you can possibly make. Tank development is the one step of progress that we have made, and I for one, would never go back to dish development if for nothing else than for the reason that it keeps the stains from my fingers. Tank development is more practical for the reason that the chemicals remain in better balance throughout the development of the negatives on account of not being subjected to so much oxygen from the air as is the case in dish developing. Let me impress upon you the importance of not over-using your tank developer. Several formulæ are given for their keeping quality, and it is generally recommended that a tank of developer can be used from day to day with equally good results This is true in a measure only, and quite a number of negatives can be developed in the same tank of developer. If it is strengthened and kept up to standard, it can be used the second, third, and possibly the fourth day with fairly good results, but every time you develop a negative you leave just so much bromide in the developer, and this bromide will eventually retard the developing action, and your negatives will look weak and under-exposed. On the other hand a tank of developer may be kept for possibly two weeks if it is covered with a floating lid to exclude the air, and is of normal temperature, provided you have not developed a great number of negatives in the same developer. Therefore, the life of a developer should be estimated by both quantity of negatives developed, and the number of days it has been standing as well as the temperature of solution. Renew your tank developer frequently, and whenever you find that you are not getting results, that are up to your standard, make up a new developer.

Many people have, to their disappointment, taken out of the washing-box negatives showing reticulation throughout the image and background, caused by softening of the gelatine in hot weather. This can be prevented by using a chrome alum solution, 6 ozs. to 1 gallon water. After developing rinse your negative quickly and put it into this solution, leaving it there for from 30 seconds to 1½ minutes, then without washing put it into the fixing bath, thoroughly fix and then wash, and you will have no trouble in hot weather. It is important that you keep this chrome alum bath at a temperature not higher than 70 degrees, and your hypo practically the same. If this bath is used the second day, I would suggest putting in a few drops of sulphuric acid, being careful that the bath is not used after it becomes alkaline. When the bath is fresh be careful that your negatives do not remain in too long, as, if so, it will be almost impossible to fix them This chrome alum intermediate bath is important for summer use, not only to keep the gelatine from frilling, but to keep your negatives from drying too dense, which is the natural result from the swelling of the gelatine in hot weather. Developing, fixing, and washing have now been considered, and the negatives should now be dried in a room with good air circulation, and free from dust, or in a drying box, as illustrated in fig. 7. After the negatives are dried they are ready for proof retouching.

HARRY WILLS.

WHITE BACKGROUNDS AND SHADOW PROFILES.

QUITE the best portrait of the professional type in the 1922 London Salon of Photography was a portrait of a lady, her shadowy profile full of exquisite detail being shown against a nearly white background. Whiter backgrounds than that shown in the Salon specimen are common in professional studio portraiture, and some time ago a London lady professional worker made a specialty of heads—full, three-quarter, and side-face—against what appeared to be, and, no doubt, was, a perfectly white background. So white was the background in some of these famous and much-admired examples that blocking-out was suspected by the uninitiated, but a close examination of the outline of the hair was enough to rule out the use of an opaque medium, blocking-out being out of the question.

White backgrounds are usually very disappointing to those who use them for the first time, or who fail to get acquainted with them after constant use. To the photographic plate white material is really white only when it is effectively illuminated, and white may very easily become a grey, a fact one is made well acquainted with when using a sheet of white cardboard as a background for flowers and still-life subjects. A white background is affected by shadow and poorness of direct light more than a ground of any other shade, and even its distance from sitter and camera will alter the actinic power of its whiteness. Even a cloud passing over the sun will grey the whiteness of a background, though the eye may not notic it. The eye knows the ground to be white both in sunshine an shadow, but the sensitive plate is inanimate with no reasonin powers, and it pictures only that which it sees, which, in the cas of a "dulled" white background, is a greyed whiteness, such a one gets when copying a black and white line subject on a proces plate on a dull day.

The inexperienced worker might suppose that "whiteness" (density in negative) could be increased by slight under-exposur with strong development, but this is not easy of accomplishment and any attempt to increase density will result in the upsetting o any delicate fones seen in the image of the figure posed before th white ground. Shadow profiles are not easy things to "light" effectively, and it is of little use to spend a lot of time arrangin a shadow portrait if the effect is to be lost in the process o developing.

It is possible to get many effective shades of whiteness and grey ness with a properly-made white background by altering the angl of it, its distance from the camera and sitter, and the blinds abou it, but to picture it at its whitest, the ground must be in a posi tion to catch the whitest of light, and, what is more important hold it, as a properly-made lantern screen will hold it, a light absorbing material being fatal to good results.

Shadow profiles (I do not mean silhouettes) are difficult enough t light effectively, and more difficult to render in such a way tha all details may be seen in the print, and in the making of such pictures one is up against a double proposition, the correct balancing of one (the shadow portrait) against the other (the white background) calling for some experience and skill.

The value of a tone or shade is estimated by its worth or im portance as related to other tones or shades, either low or high, weak or strong. When tones and shades are placed in a portrait precisely as they appear in nature the picture is technically spoken of as "good," or "true" in values; when an artist fails to pro duce them as they naturally appear—fails to produce just relation ships—his result is called "weak" in values, and when he elects to exaggerate them for purposes of artistic effect they are some times spoken of as "strong" in values. The effective rendering of the lower shades in portraiture is as important as the picturing of the higher lights, and one is made to realise this fact when taking shadow portraits.

"Autant d'hommes, autant d'avis," as my chief used to remark when I, as an assistant in a Paris studio, tried my own methods of lighting. There are, no doubt, many opinions as to the most effective method of posing and "lighting" a shadow profile against a white background. I am now—but have not always been—in favour of posing the sitter back towards a soft and much diffused light, and placing a black background or cloth as near to the "profiled nose" of the sitter as it is possible to place it without its being included in the field of view. Then by cutting down the light very judiciously between sitter and lens, strengthening it upon the background, and so balancing the whole, one may, with modern anastigmats of a large aperture and well-backed or matt-surfaced rapid plates, secure good results with a minimum of exposure. Exposures, however, must be so arranged as to secure proper shadow detail and proper density by direct development—preferably tank—because of the danger of trying to alter the usual and easy run of things by tinkering with the developer.

PRACTITIONER.

THE CLUB PHOTOGRAPHER STANDARD FOR MOUNTS.—The diversity in mount sizes, especially in exhibition prints, is a point which is continually worrying club secretaries and hanging committees. If a series of standard sizes were adhered to, much less trouble would be given and a more regular arrangement of the exhibited pictures would be possible. The "Club Photographer" has made arrangements with Messrs. W. Butcher and Sons, Ltd., to cut and market duplex mounts on card of the following sizes and prices:—

12 x 10	Packet of 12	2s. 0d.
15 x 12	Packet of 12	3s. 0d.
20 x 15½	Packet of 12	5s. 6d.
24 x 19	Packet of 12	10s. 0d.

The mounts are double-sided, combining white and light grey in one series, and cream and fawn in another. A ballot has been taken of the various societies as to the advisability of the last two sizes being adopted as the standard, and it is proposed to recommend these sizes to all exhibiting members of the various clubs.

Assistants' Notes.

Notes by and for assistants will be considered for this column. Payment for accepted contributions is made on the first of the month following publication.

Modest and Correct Demeanour.

Applicants for situations are prone to pay too little attention to demeanour at interviews, a fact many proprietors of photographic establishments are well aware of. Manners count to-day nearly if not quite, as much as qualifications, although the fact is not often stated publicly. A member of the Cambridgeshire Education Committee a few days ago, however, went out of his way to speak of the demeanour of a candidate for a post, and seekers after photographic appointments would do well to make a note of its importance. There were eighty applicants for the post, seven of whom were interviewed by a committee. One was chosen, and, in giving a report of the committee's work of selecting and appointing the man, a committeeman said, "Mr. ——— was the most distinguished of the applicants, but I do not think that was the reason why he was recommended, as much for his testimonials and demeanour at the interview." A situation-seeker's interview with a sole proprietor may be trying enough for one's nerves, but an interview with a board or committee is worse, because of the many pairs of eyes at work. The interview may, moreover, prove to be the turning-point of one's career, and it behoves the "victim" to have his wits about him, not to profess too much, and to remember that modest and correct demeanour meets with its reward.—L. T. W.

Manipulating Studio Blinds.

A generation ago a considerable amount of attention was paid to the art of studio-blind manipulation by the majority of professional photographers, but to-day it is only the third-rate worker who makes an elaborate business of it before the eyes of the sitter. Apprentices and assistants in my early days were enjoined by principals to make a good show of their task of blind-pushing by means of a pole, on the supposition that the more they manipulated the blinds the more was the sitter impressed, the latter going away with the idea that the operator took an unusual amount of trouble to get a satisfactory result.

It was then the custom—and is still the custom in old-fashioned studios—to keep the "glass-house" well lighted, to have most of the blinds out of use, and to start with as much light upon the sitter as possible. The sitter posed, blinds were then pushed or drawn until a satisfactory lighting was obtained, and I have known very quick operators (who have secured a proper lighting in a very few minutes) to fix upon a lighting, to "undo" it and to do the work all over again, lest the sitter should think that not sufficient pains were taken to secure an effective lighting. Many customers may like a lot of fuss, and applaud a performance with a bamboo stick or pole, but there are some whom it would unsettle and annoy, and in studios of the better-class photographers blind-manipulation is modified or done so unobtrusively as not to offend.

In many of the very best studios to-day operators work in the reverse way to the plan adopted by our fathers, and the system has much to recommend it. The present-day man who wishes for—and secures—the best results is he who commences with a darkened studio—every blind drawn—admitting light rather than eliminating it after the sitter has been roughly posed, and I advise all operators to make trial of the two systems.

It will be found that the play of light upon the features, its power of modelling, and the making of light and shade are better and more quickly appreciated and understood when one starts with darkness and admits light, rather than when the sitter is posed in a blaze of light which is afterwards toned down. Superfluous light dazzles the operator, and he fails to see—for a time, at any rate—the most delicate shades, whereas by starting in darkness all delicacies of tone and modelling are more clearly and quickly seen.—L. T. W.

Copying Line Drawings.

The reproduction of line subjects on slow process plates seems at first sight to be about as easy a photographic process as could be imagined. Unless conditions are favourable and exposures be kept within very narrow limits of variation from the "correct," an exact rendering of the original cannot be expected. The reason for this is that in over-exposure the light irradiates over the edges of the lines and so narrows them. The finer work thus tends to become thinner still, often to unprintable density, especially when, as far too often happens, the artist has assisted in giving the effect of delicacy to such touches as much by thinning his ink as by reducing the actual width of his line.

When attempts are made to improve matters by cutting and by subsequent intensification the fatter lines are usually widened because the reducer inside the lines has no work to do and reinforces that which is attacking the edges while on the finer parts it has veil to remove. When matters are still further complicated by uneven lighting (which means variation of exposure locally), or by faulty arrangement of lamps causing light to catch the shiny surface of modern drawing inks, the final result can easily become a mere caricature of the original.—D. C.

Exhibitions.

GLASGOW AND WEST OF SCOTLAND SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.

Under the auspices of this Society there was held last week in the McLellan Galleries, Glasgow, an exhibition of photographic art. The Society's efforts met with gratifying success, and it is hoped that it will do much to stimulate photographic business in Glasgow and the surrounding district. The exhibition is the first professional photographers' exhibition organised in Scotland. Although the Society was only formed two years ago it has already accomplished much useful work, and is now fully representative of professional photographers in the West of Scotland. The success of last week's exhibition is such as amply to justify the Society in making the event an annual one.

There were in all some 300 exhibits, the show being exceptionally strong in portraiture, but there were included many excellent specimens of commercial photographs and also a number of views of architectural and other subjects. R. Brinkley and Son had an attractive group of portraits. S. Langfier had on view some striking portrait studies delicately finished in water colour. Mr. Bairnher contributed a group of subjects, some of which were in water colour and others in sepia-toned bromide. John Doig exhibited portraiture and commercial photography, while Whyte and Sons showed a group of portraits and commercial subjects of great merit. Coloured portraits formed a prominent feature of the exhibits by the Elite Photo Company. W. Nicol Smith provided a most effective display consisting entirely of portraiture in soft tones. Among the studies shown by Messrs. Lafayette was a striking portrait of Sir Alfred Yarrow, Bart., while Messrs Turnbull and Maunds displayed among other excellent pictures a portrait of Mr. Allan Maunds, of the Glasgow School of Art. The group of subjects shown by W. Ralston were notable for their lighting effects and attracted considerable attention. Messrs. Buchanan and Armour exhibited an attractive mountain scene and also works in portraiture, while child studies in colour formed a feature of the exhibits of Wm. Elsmore. Messrs. Weir Bros. had on view a number of attractive photographs of children, and among the group exhibited by Archibald Fairbairn, an enlarged photograph of a young officer was outstanding. R. Shankland displayed a number of excellent photographs of commercial subjects.

During the whole week the exhibition was well patronised. On entering the hall each visitor was supplied by the commissionnaire at the door with a leaflet giving a few reasons in concise form why photographs should be secured.

FORTHCOMING EXHIBITIONS.

October 18 to 21. Rotherham Photographic Society. Hon. Secretary, S. G. Laversidge, Orissa, Gerard Road, Rotherham.

October 18 to 28. Portsmouth Camera Club. Particulars from the Hon. Secretary, C. C. Davies, 25, Stubbington Avenue, North End, Portsmouth.

November 4 to 11. Bournemouth Camera Club. Latest dates, entry forms, October 20; exhibits, October 31. Particulars from the Hon. Secretary, 88, Old Christchurch Road, Bournemouth.

New Books.

Patents for Inventions. By J. Ewart Walker, B.A., and R. Bruce Foster, B.Sc. London: Sir Isaac Pitman, 21s. net.

A BOOK which gives comprehensive guidance in the procedure of taking out a patent, and, so far as can be done, in patent law, is certainly one which is much to be desired. The authors may, therefore, be congratulated on having taken up this task, which is none of the easiest if the book is to be of service to people who are not lawyers. It can certainly be said that although both of the authors are barristers-at-law, they have not unduly inflicted legal language upon the reader. While their text is rather dreary reading, it is at any rate explicit and largely free from the technical expressions which occur in such abundance in the well-known text books on patent law. Probably the authors are fully conscious of the pains they have taken to set forth the legal technicalities of a patentee's rights and liabilities in a way which the layman can readily understand.

Properly speaking, the book divides itself into two parts, the first being the procedure which is followed in the course of the passage of a patent application through the Patent Office and in the opposition to a patent. One of the authors is known to us as an examiner in the Patent Office, and therefore this part of the text may be taken as embodying the official mind of the Patent Office in respect to the course which an inventor or his agent should follow. The second and larger part of the book concerns the status of the patentee after his patent has been granted and sealed by the Patent Office. Perhaps sufficient emphasis is not laid by the authors upon the fact that the granting of a patent in the ordinary course confers a kind of protection which is far less substantial than probably many inventors suppose. The Patent Office follows the routine according to the comparatively limited powers which are given it. When an inventor has got his patent, it still remains to be decided whether it is worth anything. That is left to the expensive machinery of the Law Courts, where the whole claims of a patentee may be argued afresh from the very start and evidence produced in support of or opposition to them. The optimistic inventor may be recommended to study the pages of the present work, in which are described the numerous grounds upon which a patent may be declared invalid, e.g., want of novelty, want of inventive ingenuity, insufficient description, in addition to such errors of drafting as disconformity between the provisional and complete specification. The authors support their general discussion of these important matters by references to cases which have been heard in the Courts, but they do not give any details of these proceedings—they could hardly do so, except in a very much larger treatise—so that a reader must be on the alert to recognise that his own particular case corresponds with one or other of the general defects. Other chapters deal with the rights of a patentee regarding infringement of his monopoly, the granting of licences and transfer of patents, and the text is brought fully up to date by inclusion of sections dealing with the effect of war measures upon patent rights. The book includes also the texts of the Patents and Designs Acts of 1907, 1914, and 1919, statutory rules and orders, a set of the official patents' forms, and a list of 510 cases heard in the Courts to which reference is made in the text.

PHOTOGRAPHING THE SAHARA.—According to the daily papers a fourth attempt to complete a photographic survey of the Sahara desert is to be made by a Mr. N. A. Greville and a brother. The task, it appears, was commenced nearly three years ago, and nine white men have lost their lives in the previous attempts to reach Lagos, British West Africa, from Algiers. About £15,000 has been spent up to the present, and another £10,000 will be required, there being still 400 miles of the journey to picture,

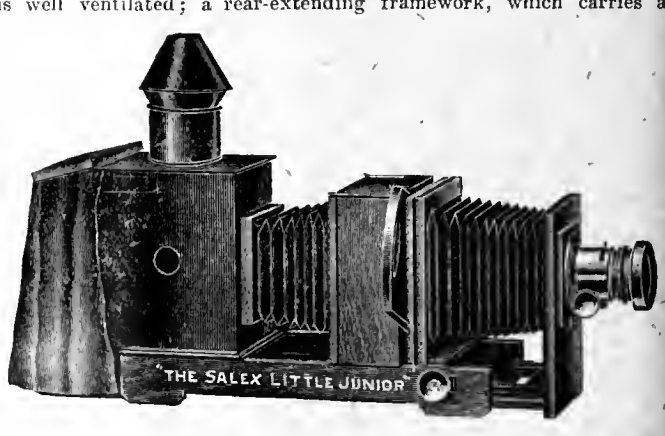
"This time," says Mr. Greville, "I propose to start from Lagos and make for Zinder, about 600 miles away. After we leave Zinder we shall be completely cut off from the outside world. We are choosing the most favourable weather, and if we are lucky shall complete the job in about six months. The difficulties are formidable. Anyone who has not experienced Sahara sandstorms cannot realise the terror of them. The sand beats down with the force of pebbles. A plain may be turned into hilly country in a night by one of these storms. On one occasion we found that the surface of the country had risen 250 ft. in places in one night.

New Apparatus.

SPECIALIST SECONDS METER.—Messrs. E. B. Fry, Ltd., 110, Pratt Street, London, N.W.1, send us this ingenious and handy appliance for timing exposures, etc., in the dark room. It consists of a bell mounted upon a wooden block. The mechanism for ringing the bell is very simple, and contains no clockwork or intricate device which could possibly get out of order. A metal tube is attached to a rocking lever mounted inside the bell, and a small steel ball runs up and down the tube. The pendulum, which is attached loosely to a hook on the lever, provides sufficient momentum to keep the apparatus working for seven or eight minutes. At one end of the stroke the steel ball runs up the tube, and at the other end it is allowed to fall upon the inner surface of the bell, making a faint but perfectly audible ring. The wooden block is attached firmly with the screws supplied in any vertical position, and the two parts of the pendulum are then screwed together so that the hook and the weight are in line with each other. The pendulum is then attached to the flat hook under the bell and set in motion. Accurate timing of seconds may be adjusted by the joint and long screw provided on the pendulum rods, but usually very little alteration is necessary. The swing of the pendulum is constant, and, whether it is long or short, the timing of the ring of the bell is always the same. The angle of swing, however, should not exceed 60 deg. if the greatest accuracy is desired.

In counting seconds by this meter, one commences exposing or timing upon the first ring. The next ring will then be one second; the next ring two seconds, and so on. We have tested the meter in the dark-room, and find it remarkably accurate. The pendulum and bell are plated and highly polished, and the meter is finished in excellent style. The price complete, ready for fixing, is 7s. 6d.

THE SALEX LITTLE JUNIOR ENLARGER.—The City Sale and Exchange, 54, Lime Street, London, E.C.3, have just introduced this compact and well-made enlarger. Strongly constructed of oak and of excellent workmanship, it is a handsome piece of apparatus, capable of good work. The light-chamber is of ample size and is well ventilated; a rear-extending framework, which carries a



curtain, is provided. The condenser is contained in a box of novel design, allowing a current of air to circulate between the lenses. The cells are not screwed into a tube, but are held by clips in the wooden frame. Thus they can be easily removed for cleaning. The negative carrier is simple yet efficient. Being quite a free member, it can be moved into any position, and is firmly held by spring clips. Focussing is by an improved

rack and pinion: the teeth of both racks and pinions are cut deeper than usual, thus ensuring smooth movement without sag or back-lash. No lens is supplied, but a specially large lens panel is fitted, allowing lenses of the Petzval type being used. The Salex Little Junior Enlarger is made in two sizes—viz., for 3½ in. × 2½ in. and ¼-plate negatives, the prices of which are £4 4s and £5 3s. respectively. Lenses may be supplied suitable for these enlargers from 12s. 6d. upwards.

THE TELEROS LENS.—Messrs. Ross, Ltd., of Clapham Common, London, S.W.4, have introduced a new type of single focus telephoto lens, which combines lightness of weight, with high efficiency and speed. The new lens differs from the "Teleentric" in that its front component is a doublet and back component a triplet. In the "Telecentric" this was reversed, the front being a triplet and the back a doublet. This alteration of the components allows the lens to be made generally smaller, and the "Teleros" is only half the weight of a corresponding lens of the older type. The "Teleros" lens, which Messrs. Ross have sent us for trial, is of 11 ins. equivalent focus, and covers a 4¼ by 3¼ plate. Its aperture is f/5 5, which allows of very rapid focal-plane exposures being made, and generally the lens is a great advance upon the older model. The enlarged image given by the "Teleros" is of great use when photographing press, sporting, and natural history subjects, while it is also of considerable value for portraiture, child studies, and pictorial landscapes. We find upon actual test of this lens that the definition at full aperture, is quite equal to that obtained by the highest class anastigmat, while for speed, and quality of the image, it is all that the makers claim for it. The lens of 11 ins. equivalent focus has a total length overall of 3⅞ ins. and requires a camera extension of 6¼ ins from flange to screen. The Teleros lens is made in five sizes, the aperture in each case being f/5.5. The equivalent focus and price of each size are as follows:—9 in. £11 10s.; 11-in., £14; 12-in., £15 5s.; 13 in., £16 15s.; and 17-in., £27 10s. An interesting booklet, with particulars of this lens, may be obtained upon application from Messrs Ross, Ltd., Clapham Common, London, S.W.4.

QUICK LEVEL TOP.—A handy little fitting for the camera tripod has just reached us from Andrew H. Baird, of 33/39, Lothian Street, Edinburgh. It is called the "Lothian" quick level top, and is intended for use as a tilting device for a camera of moderate size. It consists of two small discs with flat surfaces, one of which may be attached to the camera stand by means of the ordinary screw, while the other which contains a screw is intended to take the camera. These two discs are attached by means of small rods to a universal clamping device, which is operated by a screw and wing nut. The fitting allows the camera to be firmly held in any position, while it also acts as a turntable. The usefulness of such a fitting will be particularly realised in dealing with such subjects as flowers, carvings, museum specimens, when various positions of the camera are necessary. The stand may be firmly fixed in a level position, and the camera may then be adjusted to requirements. Thus by simply loosening the wing nut, the camera may be pointed up or down over a very wide range, or turned in any direction. The "Lothian" quick level top is small in size, and will occupy very little space in the camera bag, but being made of gun-metal it is extremely strong. The price of this handy little device is 7s 10d. post free.

New Materials.

Gevaert Lantero Plates. Made by Gevaert, Ltd., 115, Walmer Rd., London, W.10.

LANTERN SLIDE makers will thank us for drawing their attention to these plates, issued in two varieties, viz., black-tone and warm-tone. The latter are about 1-30th the speed of the former, and require an exposure of about 5 secs. at 4 in. from a 16-c.p. bulb. These plates in parti ular are a valuable power in the hands of the slide maker on account of the fine range of warm tones which they readily yield with the developer recommended by the makers for both grades, viz.:—

Metol	25 grs.
Hydroquinone	9 grs.
Soda sulphite (cryst.)	350 grs.
Soda carbonate (cryst.)	1 oz.
Potass bromide	9 grs.
Water, distilled	20 ozs.

We have also used the metol hydroquinone-thiocarbamide developer recently recommended by Mr. J. Dudley Johnston for these plates, and have obtained some especially pleasing tones, ranging from blue to dark chocolate brown. Four solutions are required, each of which will keep indefinitely under the usual conditions:—

Solution A:

Metol	44 grs.
Hydroquinone	30 grs.
Sodium sulphite (cryst.)	1 oz.
Sodium carbonate (cryst.)	1½ ozs.
Water	20 ozs

Solution B:
Ammonium carbonate ... 10 per cent. solution.

Solution C:
Ammonium bromide ... 10 per cent. solution.

Solution D:

Thiocarbamide	33 grs.
Ammonium bromide	11 grs.
Water	10 ozs.

Printing by contact and using an Edison Fullolite 60-watt lamp, 5 secs. at 2 ft., was found to be the unit of exposure with negatives of average density. For bluish tones the factor is 6, making the exposure 30 secs. The developer is compounded as follows:—

Solution A
Metol hydroquinone developer ... ... 6 drams.

Solution B:
10 per cent. ammonium carbonate 1 dram.

Solution C
10 per cent. ammonium bromide ... 1 dram

Solution D
Thiocarbamide solution ... ... 30 mins.

By varying the exposure and temperature of the developing solution many fine tones ranging from blue-black to purple may be obtained. For chocolate and brown tones a slight alteration of the developer is found advisable. The exposure factor for sepia tones is 5, thus the exposure under the conditions of lighting mentioned above was 25 secs. The developer is as follows:—A, 6 drs; B, ½ dr.; C, 1½ drs.: 10 per cent. hypo, 20 minims.

For the black tone plates, the metol-hydroquinone developer, solution A may be used alone. The plates give good dense blacks free from "greenishness," and have particularly transparent high lights. There is one point we noticed when using the Gevaert lantern plates, namely, that fixing takes place very quickly in the ordinary 20 per cent. hypo solution. This is a great advantage, but it should not lead the worker to curtail the time of fixing unduly. Ten minutes should be allowed to ensure complete fixation, and the plate should be moved about in the solution for the first thirty seconds. While clearing with Farmer's reducer is a great advantage in lantern slide making, the Gevaert plate requires very little clearing, since the shadows veil scarcely at all. From a thorough test of both the black and warm tone Gevaert lantern plates we have every confidence in naming them as materials of pre-eminent quality for the slide maker.

PORTRAITS OF H.R.H. THE PRINCE OF WALES.—Some excellent portraits of H.R.H. the Prince of Wales, in scout uniform, were taken at York House on Saturday, October 7, prior to his departure for the great scout rally at Alexandra Park. The portraits were taken by Mr. Cyril D. Venning, of Messrs. Val L'Estrange (1916), Ltd., of Knightsbridge.

Meetings of Societies.

MEETINGS OF SOCIETIES NEXT WEEK.

MONDAY, OCTOBER 16.

Birmingham Phot. Art Club. Annual General Meeting.
Bradford Phot. Soc.—"What the Society's Enlarger Can Do." Bernal Riley.
Dewsbury Phot. Soc.—"Transferotype." W. H. Hammond.
Kidderminster and District P.S.—"Norway—A Peep at its Folk and Fjords." F. W. Pilditch.
Southampton C.C.—"Across Africa in War-time." J. B. Simester.
Wallasey Amateur P.S.—"Killarney." J. Mansell.

TUESDAY, OCTOBER 17.

Birmingham P.S.—"Belgium before the War." W. J. Ballard.
Bournemouth C.C.—"Enlarging." J. Thomas.
Cambridge P.S.—"Apparatus and How to Use it." The Secretary.
Exeter C.C.—"Prehistoric Man." W. S. Lewis.
Hackney P.S.—Outing to Winchelsea and Rye.
Halifax Scientific Soc.—Social Evening.
Leeds P.S.—"The Great School of Portraiture in England." H. Thompson.
Manchester Amateur P.S.—Beginners' Print Competition.
Morley Amateur P.S.—"Round About Some Yorkshire Villages." W. E. Cundill.
Slough and District Y.M.C.A. Phot. Club.—"Amateur Photographer" and "Photography," 1921, Prize Slides.
South Glasgow C.C.—Lantern Slide Monthly Competition and Criticism of Slides.

WEDNESDAY, OCTOBER 18.

Borough Polytechnic P.S.—Third Print Competition.
Croydon C.C.—"A Dark-room under the Tiles." J. C. Coffin.
Edinburgh P.S.—"Bromide Enlarging." A. H. MacLucas.
Edinburgh P.S. (Oct. 18-30).—Exhibition of Rambling Club Prints.
Partick C.C.—"Gaslight and Bromide Printing." T. Horn.
South Suburban and Catford P.S.—"After Dark." H. Creighton Beckett.

THURSDAY, OCTOBER 19.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday October 10, the President, Mr. W. L. F. Wastell, in the chair. The twenty-fifth annual Traill-Taylor Memorial Lecture was delivered by Dr. Reginald S. Clay, who took as his subject "The Photographic Lens from the Historical Point of View." His discourse was a rapid and highly concentrated review of the development of the photographic lens. It is a large subject, abounding in technicality, and to cover the whole of it from the time of Chevalier's first lenses for Daguerre to the most recent improvements in photographic objectives, called for a degree of condensation which necessarily gave the lecture the form of an amplified chronology. However, Dr. Clay contrived to compress an immense amount of historical matter, particularly in reference to the lenses of the English optical firms within the limits of the time at his disposal. Any report of what he said must inevitably be very incomplete. Some details may be given, and the student of this branch of the history of optics referred to the full text of the paper which is to appear in the November issue of the "Photographic Journal."

Referring briefly to the earliest mention of lenses, Dr. Clay said that glass globes filled with water were known to the ancients for their magnifying power. It was also probable that polished transparent stones or quartz were made use of for magnifying or even as burning glasses. The camera obscura, which was the origin of the photographic camera, was first mentioned by Leonardo da Vinci (1452-1519), who used a pinhole to form the inverted image on a screen. Dr. Clay considered that the first mention of a camera with a lens was made in 1550 by Hieronymus Cardano, but a Venetian nobleman, Daniel Barbaro, in 1568 not only used a lens in his camera, but a diaphragm as well.

Speaking of the achromatic lens, Dr. Clay said that an Englishman, W. Chester More Hall, in 1723, had such a lens made for his private use, but it was incorporated in a telescope some time before Dolland's publication. The evolution of the photographic lens began in 1839 when Daguerre and Fox-Talbot published their discoveries. Daguerre's lens was one of meniscus form working at $f/14$. It was made by Chevalier to Wollaston's formula. The Petzval lens was the outcome of a conversation in 1839 between Prof. A. von Ettinghausen, of Vienna, and Joseph Max Petzval, and was made by Fredrich Voigtländer. This was a wonderful lens, said Dr. Clay, as it had continued to be made in its original form for some seventy years. The aperture of Petzval's original lens was $f/6$, and Andrew Ross made it in an improved form working at $f/4$.

Dr. Clay went on to speak of the doublet lens made of two cemented achromatic lenses by Thos. Ross in 1841. Davidson, who also made a symmetrical doublet in the same year, failed, like Ross, to discover the advantage of this construction in reducing distortion, etc

Dallmeyer's entry into the field was in 1860, when he took out a patent for a separated triplet of which all three components were cemented achromats. The curious panoramic lens of Thomas Sutton, patented in 1859, was next described by the lecturer. It was, he said, a globular shell filled with water. Owing to the variation of the refractive index in the liquid, due to changes of temperature, this was not a great success. Referring to the aplanatic lenses of Steinheil and Dallmeyer, Dr. Clay said that the latter's wide angle rectilinear lens invented in 1866 consisted of two flints, and worked at $f/15$. In 1874 Ross placed upon the market a portable rapid symmetrical lens calculated by F. H. Wenham.

The new glasses of the Schott Glass Works, Jena, proved of great assistance in the development of the photographic lens, and the lecturer proceeded to show how glasses made by combining the three classes of glass, viz., old crown, flint, and new barium crown, could be made to produce a lens which was achromatic, anastigmatic and aplanatic. If two components having these qualities were combined the lens could also be made orthoscopic, and could easily be given a flat field. Speaking of the Concentric lens, the first anastigmat, Dr. Clay said that Schroeder, who was calculator to Messrs. Ross, realised that this lens was not spherically corrected, and proceeded by combination of the two types of crown glass, to construct in 1892 a symmetrical cemented triplet, which overcame the difficulty. This lens was supplied to the Greenwich Observatory for stellar photography, and is still in use there. The Telecentric lens of Ross was calculated by Bfelicke, and had a short back focus. This enabled it to be used in ordinary cameras, especially of the reflex type, and it became very useful for taking sporting photographs. The first lens of this type was made by Martin, but it was not well corrected. The Teleros lens, which was an improved form of Telecentric has just been put on the market and could be made much lighter in weight than the Telecentric.

Speaking of the origin of lenses of the telephoto type, Dr. Clay referred to the patent taken out in 1891 by T. R. Dallmeyer for a telephoto. In 1899 Messrs. Dallmeyer introduced their well-known Adon lens. The Busch Bis-Telar, with fixed separation, appeared in 1905, while the Zeiss Magnar followed in 1906. A new large Adon with a fixed separation and focal length, and made in two sizes with apertures of $f/4.5$ and $f/6$ respectively, appeared in 1912, while in 1919 the Dallon, calculated by Mr. L. B. Booth, was placed on the market. This lens consisted of two cemented pairs, constructed of special glass, and the air space being eliminated, pincushion distortion was reduced to a minimum. Dr. Clay then referred to the uses of lenses by the Air-Force, and remarked that at the outset the 8½-in. focus Ross-Zeiss Tessar was found suitable for the work. However, lenses of longer focus, and in greater number, were soon required, and the "Airo Xpres" of 20-in. focus, working at $f/5.6$, was evolved. Referring to the introduction of the Cooke lens, Dr. Clay said he did not think that the great advance that this type marked was as well appreciated in this country as on the continent. The introduction of this lens formed a starting point for a new method of lens construction, which had had, and would continue to have, many fruitful applications. Mr. H. Dennis Taylor was responsible for the working out of this principle, and patents were taken out in 1893, 1895, and

1898. During the war a special Cooke lens was evolved. This, said Dr. Clay, was the "Aviar," which was designed by Arthur Warmisham. It was a split divergent lens, an idea which originated in the mind of Dennis Taylor, but was never developed; the actual carrying out of the system was left to Mr. Warmisham.

Dr. Clay said he would like to point out that the Zeiss Unar and Tessar were based on the same principles as the Cooke lens, and that he would not be far wrong in saying that nearly all the modern rapid anastigmats were modifications of the Cooke, and built upon the same foundation.

Comparing the Cooke Aviar with a captured Zeiss lens, the lecturer said that Mr. John H. Gear selected as the superior negative the one made with the British lens.

Speaking of the iris diaphragm, Dr. Clay said that one was made in 1816 by Nicéphore Niépce, this was now in the museum of Châlon-sur-Saone. It was, however, Messrs. R. and J. Beck who were the first to fit the iris diaphragm to photographic lenses; this was in 1882, and they were regularly supplied with the Beck rapid rectilinear lens in 1887.

Speaking of earlier forms of lens stops the lecturer referred to the revolving diaphragm of John B. Dancer (1856), which was fitted in front of the lens. Lake Price had inserted diaphragms in a slot in the lens tube, but in 1857 or 1858 Waterhouse "improved the notation," said Dr. Clay, and so gave the system his name.

The Isostigmar lenses were introduced by Messrs. Beck in 1906, and were interesting because they could be made to cover a field of 85 to 90 degrees at f/16, and were thus the first wide angle lens with such an aperture. Messrs. Beck was also responsible for another simple idea, viz., the use of magnifiers in front of a lens. These were introduced in 1894, and were made for the Frena camera. In a final review of the development in the manufacture of lenses since 1840, Dr. Clay said that we first had the wonderful achievement of Petzval, who produced at the first attempt a lens which held its own almost unchanged for more than sixty years. The next step was the invention of the rapid symmetrical lenses of Dallmeyer in 1866, and Steinheil in the same year. These two great inventions in lens manufacture were followed, first by the anastigmats of Hugo Schroeder, Paul Rudolph, and Emil von Hoegh in 1890, 1891 and 1892, following the invention of the barium crown glass of Schott, and finally by the Cooke lens of Dennis Taylor of 1893. In conclusion, Dr. Clay considered that British opticians might claim to have borne their share in the history of lens making in spite of all the praise that has been lavished on the Germans.

A most hearty vote of thanks was accorded to the lecturer on the proposition of Mr. W. B. Ferguson, seconded by Mr. A. C. Banfield. The proceedings ended with the handing to Dr. Clay of the medal struck each year for presentation to the Traill-Taylor lecturer.

CROYDON CAMERA CLUB.

Mr. B. J. Rose opened the formal session with a capital exposition entitled, "Photographic Odds and Ends," mainly of constructional order and mostly requiring diagrams to describe. He started, he said, under difficulties, having experienced three misadventures. The first was suddenly advanced from March next to the opening night by an imperious secretary; the second had reference to his son, who had assisted by bringing the wrong bag of materials, and had been requested to return home for the right one; and the third arose out of an encounter with a wasp (since deceased), which necessitated a bandaged hand. Nevertheless, despite these trials and tribulations Mr. Rose did right well, and was as ingenious as ever.

Contorted portraits, first shown, caused considerable amusement, and are simply produced. A piece of card is bent into a half-circle and retained in position by glued on pieces. Paper side-runners permit of a bromide print being retained in the same curvature and photographed *in situ*. Concavity and convexity towards the lens respectively introduce different effects, and further variation is afforded by placing the curved cardboards with the plane of the circle either horizontal or vertical. The radius of the half-circle used was 2 inches, and in practice a little less than a half-circle is employed. Naturally, a small stop is demanded when making the negative. He suggested by employing much larger radii unduly long faces might be slightly broadened and vice versa, and be more acceptable to the sitter than a faithful representation.

Next came pinholes. A fitment for a camera front consisted of a sliding piece carrying pinholes of varying diameters, any one of which could be used at will. The largest hole was $\frac{1}{8}$ in. in diameter to permit of focussing, and also of the insertion of a narrow rod graduated in inches. By putting this against the focussing screen the extension was shown at a glance. A very simple but neat device.

"Intimate Photography" on C. P. Crowther's lines, pushed, possibly, a shade further than this talented advocate of short foci lenses would approve, was strikingly exemplified by a pinhole portrait of the lecturer, the pinhole during exposure being exactly 6 in. distant from the face. A photograph made by this means fully demonstrated the importance of the nose, even all indications of character were emphasised, though the pose is less than three-quarter face. As a member observed, much unchristian satisfaction would be felt by bashing such a nose.

But joking apart, the photograph was instructive in one respect in showing that in portraiture a near viewpoint *per se* affords no suggestion of stereoscopy. With a large aperture lens the case is entirely different, as the nearer the approach the more it sees round the corner, so to speak, and pseudo-stereoscopic relief is induced, often to a startling degree.

Tips on making many other appliances followed, the demonstration being brought to a conclusion with a consideration of photographic Christmas cards. A device in connection with the last may be useful to many. Frequently it is desired to set off a diagram or drawing, but carbon paper is out of the question owing to its greasy nature, which repels ink. In lieu thereof Mr. Rose takes a sheet of tissue paper, rubs over it a block of Nixey's blacklead, removes as much lead as possible with a rag, and the substitute is complete. Set off lines are plainly visible, and can be removed if required with india-rubber.

Mr. Sellors bitterly remarked that some years ago, like the silly ass he was (cheers), he started making Christmas cards, which were welcomed with a chorus of praise by the household. They were absorbed not by the dozen, but by the gross, till the gross grew into a ghastly nightmare. Never again! Mr. Rose, in reply, was understood to say that he went in for mass production, which involved but little trouble. One simply chucked the gaslight papers into the printing frame one after the other (which is not unusual) and then chucked them into the developer, hypo bath, and washing water, and there you were. "In future I am not," said Mr. Sellors with grim determination.

EDINBURGH SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.

Meeting held at 116, Hanover Street, Edinburgh, on Monday, October 2, at 8 p.m. Present Miss Bertram, Messrs. J. Campbell Harper, Norman Thomson, George Ayton, George Balmain, Swan Watson, J. B. Johnston, E. D. Young, W. B. Hislop, G. G. Morrison, and George M. Aikman, Mr. J. Campbell Harper, the President, in the chair.

In welcoming the members at the first meeting of the session, the President stated that during the recess he had been considering very seriously some useful and permanent work which the Society, as well as its individual members, might do to make themselves a more vital and effective force in the world and in business. He was of opinion that what was required was simply more courage and determination to carry out the schemes and build some of the castles which, up till now, have only been "in the air." Lack of courage and the dead-weight of fear of unsatisfactory results in new schemes must be got rid of, if the Society and its members were to succeed. He stated that it was said that artists are born, and not made, but he maintained that the art world is composed more of men who have made themselves artists by courage and determination with years of training. He was anxious that the Society should attain a higher level, and should zealously pursue the carrying out of their schemes. He thought there were many things the Society could do if the members attended and had the courage to express their opinions. He suggested that the question of electric light charges should be investigated, and he also strongly recommended the holding of a congress and exhibition in Edinburgh as a great stimulant towards raising the status of the professional photographer and the quality of his work. It is essential that every grade of work should be included in the exhibition, as was done in the International Exhibition which was held in London last month. He considered such an exhibition one of the most encouraging and interesting things from a professional photographer's point of view.

The Secretary read the report on the instructive and appreciative lecture delivered by Mr. Lawrence, of Messrs. Kodak, Ltd., in Edinburgh last week, which was approved.

Mr. Young stated that the classes for posing and composition and retouching would commence in the College of Art this week, and he urged master photographers to endeavour to get their assistants to join one or other of the classes, especially the retouching class, as it was most important that every assistant, who is to be of any use to his employer, should have a training in drawing. The President intimated that Mr. Hoskins had been appointed teacher of practical chemistry and optics in place of Mr. Hislop. He stated he had had an interview with him, and he thought he would make an excellent teacher, and he asked the members for their support to the class.

It was agreed to hold an informal meeting in the Victoria Café on Monday, October 16, at 8 o'clock, to discuss as to holding a congress and exhibition in Edinburgh.

A discussion took place on the question of the affiliation of the Society with the Professional Photographers' Association, London. Some of the members felt that nothing was to be lost but much was to be gained by becoming affiliated to the P.P.A., while other members considered that this Society would lose its independence by becoming affiliated. It was resolved to discuss the matter further at the informal meeting to be held this month.

Mr. Young brought before the meeting a pamphlet on a method of class study in the course upon "Appreciation of Fine Arts," written and conducted by Mr. F. C. Tilney. He said that from the statement the course appeared to be most helpful to professional photographers, and suggested that a number of the members should combine and take the course. It was agreed to bring the matter before the next informal meeting, when it was hoped there would be a larger attendance.

A vote of thanks to the chairman concluded the business.

News and Notes.

The Liverpool Amateur Photographic Association has been very kindly lent the extraordinarily fine "Camera Portraits" by Mr. Walter Stoneman, F.R.P.S. A House Exhibition such as this of work of such high technical merit and of such a unique gathering of famous people is very much appreciated by photographers and others living far from London.

Richmond Camera Club.—This old established society, whose headquarters are at the Cottage, Public Library, Richmond Green, sends us its syllabus for the session October, 1922, to May, 1923. Many well-known names are included in the list of lecturers, and their subjects show much variety. We predict an interesting and instructing session for the members.

Postcard Printing.—The London and Provincial Photographic Service have removed to more commodious premises at 97, London Road, Leicester. This firm are making a specialty of high-class postcard work, and send us specimens of their cards in black and sepia. These are extremely well done, and at the low prices charged should command good business.

The Western Australian Camera Club.—The fifth annual report and statements of account for the year ending June 30, 1922, has just reached us. The club is undoubtedly in a very healthy condition, both financially and as regards membership, the number of the latter now reaching 118. The exhibition of members' work, which was held November 21 to 26, 1921, was eminently successful, and attracted many visitors, 250 prints being hung. The committee of management elected on August 31, is a particularly strong one, consisting of keen energetic members, who should help to further the success of the Club.

Photographic Golfing Society.—The autumn meeting of the Golfing Society, which draws its membership from photographic trade circles, was held last week in Norfolk, the headquarters being the Links Hotel, West Runton. There was a representative attendance of members of the photographic trade, as shown by the group photographed by Mr. H. H. Tansley, of Sheringham. Reading from

Photograph by H. H. Tansley.

The Photographic Golfing Society. Autumn Meeting at West Runton.

left to right the members of the industry included in the group are as follows:—Front row: T. M. Illingworth, J. M. Isaacs, S. Adamson, Frank Butcher, Fred T. Butcher, and C. Stanley Houghton. Middle row: J. J. Shepherd, E. W. Houghton, J. Harrington (Sydney), Gerald M. Bishop, C. S. Downing (with challenge shield), Major D. Geddes, E. Smith, Arthur C. Brookes. Back row: C. E. Case, F. W. Greenwood, A. J. Child, J. W. Thompson, W. E. Mitchell, A. W. Brookes, J. S. Boyesen, A. H. Starnes, W. H. Burditt, W. F. Butcher.

The Northern Exhibition.—The tenth Northern Exhibition of Photography is announced to be held from February 5 to March 3 in the City Art Gallery, Manchester. The exhibition will be divided into four sections, comprising pictorial photographs in monochrome or colour, lantern slides, colour slides, Autochromes etc., and natural history and scientific photography. Fifteen awards will be at the disposal of the judges, and will be in the form of decorative plaques. The pictorial section will be judged by Messrs. F. C. Tilney and J. Dudley Johnston, and the technical and scientific sections by Dr. G. H. Rodman. The prospectus and entry forms are now available and may be obtained from Mr. Walter Johnson, 30, Hartingdon, Road, Chorlton-cum-Hardy, Manchester.

Cameras for Photographing Moving Objects.—In a patent specification, No. 184,189, not yet accepted, of H. L. Cooke, 148 Mercer Street, Princeton, New Jersey, a camera for taking photo

graphs from a moving body is described. The camera is so mounted that it can be moved continuously to compensate for the apparent motion of the object to be photographed, and may be used on aircraft, motor car, ship or train. In the form described, a camera is mounted together with a telescope and a gyrostat in gimbal rings, the axes of the three instruments being parallel, and the centre of gravity of the entire movable system being situated at the intersection of the gimbal ring axes. Adjustable torques are applied to the gimbal ring axes by adjustable springs, to produce a gyrostatic precession of the entire movable system in the desired direction and at the desired speed. Time exposures are thus rendered practicable, and the camera may be fitted with a wide-angle lens.

Art Study for Photographers.—During the summer months, when the ordinary activities were suspended, the Pictorial Group of the Royal Photographic Society formed a circle to study the course of lessons in the Appreciation of the Fine Arts devised by Mr. F. C Tilney. It proved eminently successful, and should mark the beginning of a more serious appreciation of the problems of the graphic arts which are involved in photography as well as in the arts of painting and other graphic media. Photographers are apt to imagine that technical skill in photographic manipulations is all that is required for pictorial success, unaware, apparently, that as an art medium, photography is conditioned by precisely the same considerations that apply to the other arts. On this point the course of lessons proved of inestimable value. They are loaded with information which the ordinary photographer seldom takes the trouble to absorb. That is to say, they are designed for the lover of art, whether he be a photographer or not. Of their value to the camera pictorialist there can be no doubt, and if any of our photographic societies can find twenty-one members sufficiently in earnest to subscribe their four shillings (or fewer at the proportional higher rate) and tackle the lessons seriously, the standard of pictorial work will undoubtedly be greatly improved. Club secretaries please note. Full information can be had from Mr. F. C. Tilney, Walden, Cheam, Surrey.

Correspondence.

**** *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

**** *We do not undertake responsibility for the opinions expressed by our correspondents.*

THE 1923 P.P.A. CONGRESS.

To the Editors.

Gentlemen,—We want what we want, when we want it, exactly, and we want the congress held in the spring, when we have left the trying time of winter months behind, and can spare a few days, and an evening or two, without much trouble. Looking forward to the best season we have had, and the fellows we meet, the things that we see, the things that we hear, are conducive to that optimist feeling, that is so necessary; but September! of all months! The wonder is that 298 got there. I can only surmise that the majority must be of the favoured few, with long purses, or their businesses under the control of assistants. Last month it took me all my time to wangle a Thursday afternoon.

Faithfully yours,

James W. Carrick

540, Green Street, Upton Park, London, E.
October 7.

To the Editors.

Gentlemen,—I have seen Mr. James Speight's letter which appeared in your last issue. May I be allowed to remind all members of the P.P.A. that any suggestions or complaints they have to make, will, if addressed to the Secretary receive every attention and consideration. The Council are quite as anxious to carry out the wishes of the members when conveyed to them direct, as they are when their attention is called to them through the medium of the Press.—Yours faithfully,

Alfred Ellis, Secretary.

2, Vinery Villas, Hanover Gate,
London, N.W.8.
October 9.

To the Editors

Gentlemen,—I was very pleased to see the letter from Mr. James Speight and entirely agree with him. I have been a member of the P.P.A. since its formation and attended every Congress except the last, and when the suggestion was first made of holding the Congress in September I wrote you a letter protesting against the alteration, but not a single member backed me up. The small attendance, however, shows very well that a mistake has been made, and I hope the Council will see their way clear to arrange the time to coincide with the Photographic Fair.—Yours faithfully,

Fred Gegg.

Corinium House Studio, Evesham,
October 9.

To the Editors.

Gentlemen,—Your correspondent has admirably and fully expressed the opinion of a good many provincial members, who, like myself, are quite unable to attend an autumn congress. It may be very convenient for those living in or near London, but it is not so for us country members. I have always enjoyed attending the May meeting and seeing a good show of apparatus and materials, but shall be debarred for the future unless a vote is taken as suggested and the arrangement possibly altered. I trust that will be done and the country members given a chance.—Yours truly,

A Staffordshire Member.

To the Editors.

Gentlemen,—I would like to support Mr. James Speight's suggestion that a referendum of members be taken re the September Congress. To me it seems a great pity to have it apart from the date of the Photographic Fair, and the time of year must certainly be awkward for a great many. Besides the children going back to boarding schools (a big business) there are a lot of weddings in September which cannot be missed, also it is so close on one's summer holiday. I had written for my badge but could not get to the recent Congress, and would not like to risk a week away at this time of the year. Of course if September suits the majority, well and good, but some of us would like to know that we are in the minority.—Yours faithfully,

T. Everitt Innes.

The Studio, St. Petersgate, Stockport,
October 9

Photographs by Wireless.—A special article in the "Daily Chronicle" last week dealt in an interesting manner with some of the latest developments in the sending of photographs by wireless. It was stated that in the research laboratory of the General Radio Co., at their Twyford Abbey Works, photographs have already been received by radio, and though the invention is not yet beyond the experimental stage, remarkable results have already been obtained. Those who have seen the radiographs say the pictures are quite good, and generally recognisable. Though the main criticism is that the clarity of the pictures leaves room for improvement, this will be remedied in time. The fact remains that wirelessed pictures are an actuality to-day. The pictures which have been received by the General Radio Co. are wirelessed direct on to a specially made sensitive celluloid film, which is afterward developed. It was only in 1905 that the success of Professor Korn, of Munich University, in telegraphing portraits was heralded as a marvellous invention. He then claimed to have transmitted photographs over a resistance equivalent to more than 5,000 miles. In 1907 pictures were cabled by newspapers as experiments, the process being rather complicated and costly. Since the armistice the most notable enterprise has been the cabling of pictures across the Atlantic in 1920, thus demonstrating in certain circumstances the value of the invention either in newspaper hands or in criminal investigation. By means of a luminous circular plate, against which photographs were projected, pictures were telephoned in the same year from Antwerp to Paris in eight minutes. Mr. Thorwald Anderson, a Dutch inventor, has claimed to have improved upon this method by coding pictures to this country by cable. Mr. T. Thorne Baker has also been working for some years upon sending pictures by wireless, and two years ago he claimed to have an improved system. Now the wireless picture, as Senator Marconi prophesied, has arrived, and, though the greatest secrecy is being maintained by the officials of the General Radio Co., it is known that the method of direct radio photograph transmission is such an improvement on previous efforts that its appearance as a commercial project is shortly anticipated.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

A. D.—Black and white powder colours, as used for finishing enlargements, may be obtained from Messrs. Reeves and Sons, 4, Farringdon Avenue, London, E.C.4. The airbrush would be the best means of covering the background in your print, but if this is not available oil colours may be used. These may also be obtained from Messrs. Reeves, as above.

W. K.—We have no further information than that contained in the specification. No doubt the inventor, M. C. E. Bredon, 44, Rue de Cambrai, Paris, would be glad to give you further particulars. We do not imagine that exposure would be more rapid than in other one-exposure cameras of simpler construction, such as that of Mr. E. T. Butler, which is upon the market here.

Electric.—We should advise you to do away with the Jupiter lamp and in its place fix a half-watt bulb of 2,000 c.p. fitted with a Barkay reflector. A standard lamp of 3,000 c.p. should also be provided. This would enable you to control the lighting, as the lamp could be moved into any position. The General Electric Co., Magnet House, Kingsway, London, W.C.2, make a specialty of studio lighting, and their catalogue would be of use to you.

B. M.—Possibly the prints are not fully toned. This would account for a certain amount of weakening, but not of bleaching. We suppose you are using an ordinary fixing bath of plain hypo, with not more than 2 or 3 ozs. of hypo per 20 ozs. of water. If stronger than this, or if the bath contains additions, such as acid, alum, etc., there is a certain liability to reduce the depth of the prints, though not to the extent of bleaching them. So far as we know, there is no means of restoring the depth of P.O.P. prints which have been bleached in the fixing bath.

A. S.—You cannot do better than use half-watt lamps in your studio. These, if fitted with Barkay reflectors, will be very efficient. The General Electric Co., Magnet House, Kingsway, London, W.C.2, would give you particulars of their studio lighting outfits. The Barkay reflectors may be obtained from W. J. Bartholomew and Co., 40, Gerrard Street, London, W.1. The lens and camera depend entirely upon the amount of money you are prepared to expend. We should advise you to consult the professional price lists of the well-known apparatus makers. You will have no difficulty in getting full length figures in your studio using an 8¼-in. focus lens on a half-plate.

T. W.—(1) A fair amount of practical work in both studio and dark-room is absolutely necessary. Text-book instruction is very useful, but the practical knowledge is the principal thing. (2) "Science and Practice of Photography," by Chapman Jones, is a volume which should suit you. It is now out of print, but may be obtained (second-hand) from Messrs. Foyle, 121-123, Charing Cross Road, London, W.C.2. For illustrations of apparatus we would refer you to the "British Journal Almanac," where many advertisements of cameras and other accessories are given. (3) Messrs. Jonathan Fallowfield, Ltd., 146, Charing Cross Road, London, W.C.2, make a specialty of "while-you-wait" photography, and would give you particulars of the apparatus, etc., needed. The "British Journal Almanac" gives particulars of all the most up-to-date processes and apparatus used in photography, together with formulæ and working details.

J. T.—The stains in your films are due to insufficient fixation, while the white powdery deposit on the surface is due either to the wash water containing a large proportion of lime, or to the films not having been sufficiently washed. We should advise you to soak the films in strong hypo solution, say 6 ozs. hypo to 1 pint water. They may be left in this solution for 10 minutes, but should be watched carefully. If this does not remove the stain, probably thiocarbamide may be of use. Make up the following :—

Thiocarbamide	90 grs.
Citric acid	90 ,,
Water	20 ozs.

Wash the films very thoroughly to remove hypo and carefully wipe each side with wet cotton wool before placing them in this bath. A few minutes only may be necessary to remove the stain, but we are afraid you will not completely clear your films as the stain seems to be of fairly old standing.

Skipress.—You will find some useful hints on engineering photography in the little book "Commercial Photography," issued by our publishers, price 1s. 3d. post free. The only other book on commercial photography, including that of engineering subjects, is a very excellent American manual, "The Commercial Photographer," published by F. V. Chambers, 636, South Franklin Square, Philadelphia, U.S.A., price 4 dollars. You would have to send direct for it. The best book on retouching is Johnsons "Retouching," by Bruce and Braithwaite, for which our publishers are special agents, price 5s. 4d. post free. We advise you to get a camera of the square bellows or slightly taper pattern. For such work you want at least two lenses, namely, a wide-angle of about 5 inches focus and an anastigmat doublet of 8 or 9 inches focus. The latter need not be one of the ultra-rapid $f/4$ lenses, but is better one of the $f/6.8$ or $f/7$, which is listed by most of the leading makers. A lens of this type is better for covering the plate when the lens front is raised.

M. M. L.—It would be impracticable to obtain a light sufficiently intense for studio portraiture from dry batteries, accumulators, or similar electric storage apparatus. In your circumstances we think you have no alternative between flashlight and incandescent gas. The latter has the same defects as the petrol light you are using, namely, not enough light and too much heat, but the best of these gas installations, the "Howellite," of Messrs. J. J. Griffin & Sons, Ltd., Kemble Street, Kingsway, London, W.C.2, suffices for exposures of, say, 4 or 5 seconds on a fast plate with an $f/4$ lens. As regards flashlight, it would be absolutely necessary to fit up a big chamber to carry off the smoke. Although this form of light is scarcely used in this country, it is largely adopted in France and in America, where portrait photographers have been to a good deal of trouble in fitting up smoke cabinets as part of the studio. Of the two, we should think you would do best with flashlight, and if that is so, it may be of service to you to mention the name of Mr. D. Charles, 50, Webb's Road, Clapham Junction, London, S.W.11, who is a good man to draw up for you, and supply, if necessary, a specification as regards the design and fitting of a smoke chamber and ignition of the powder.

Contents.

SUMMARY.

In a contributed article Mr. A. H. Hall makes some suggestions for obtaining greater depth of tone in prints. Among other methods he mentions the use of smooth baryta-coated paper as the transfer paper in carbon printing, and also the application and subsequent printing of a film of bichromated gelatine. (P. 633.)

In a recent paper in "American Photography," Mr. E. J. Wall sets forth the chemical relation which the alkali in a developing solution bears to the developing agent proper, and from these considerations evolves a table showing the developing equivalents of the various alkalies. (P. 634.)

In his paper this week, Mr. J. Effel has some more things to say on the part which psychology plays in the conduct of a portrait studio. (P. 631.)

In a leading article, we consider the practice of portraiture in ordinary rooms in relation to the fashion for unorthodox lightings which has been created by the spotlight and other means. (P. 630.)

Several correspondents return to the subject of the time of year for the next Congress of the Professional Photographers' Association, and express the view that a referendum should be taken among the membership. (P. 643.)

Commercial makers of photographs for advertisements may well consider the greater favour which is being bestowed on soft-focus effects by advertisers of taste. (P. 629.)

Condensation of moisture on lenses is not limited to their outdoor use in bad weather, but occurs even in studios, particularly during the winter season with its variations of temperature. (P. 630.)

The advantages of the auxiliary spot light for the production of distinctive effects and also in supplement to daylight are the subject of a paragraph on page 629.

At the Royal Photographic Society on Tuesday evening last Major F. C. V. Laws, R.A.F., in a lecture on the progress of aerial photography, gave instances of the remarkable improvement in the technique of aerial-photographic methods, and described some recent important applications of aerial photography. (P. 640.)

By optical copying of an opaque negative in place of contact printing from one on a transparent support economy of material can be effected, although at some sacrifice of quality. (P. 630.)

The misuse of the dark-room towel is perhaps more largely responsible for chemical contamination than any other cause. (P. 630.)

The preventible causes of blisters on prints are described in the current issue of the American "Studio Light." (P. 636.)

A process of sensitising resin with bichromate is the subject of a recent patent specification. (P. 637.)

Ex Cathedra.

Soft-Focus Commercial Work. In this country it is almost invariably the practice to use absolutely sharp photographs for newspaper and magazine advertisements. This is doubtless due to the fact that it is generally considered necessary to work up the prints liberally in body colour before handing them to the process-man. This is obviously out of the question with photographs made with lenses giving pronounced diffusion. On the other side of the Atlantic soft-focus pictures are now becoming quite a feature in the advertising pages, particularly of such periodicals as use the rotary photogravure process. The effect is rather pleasing, and doubtless often attracts the cultured eye when the usual brilliant result upon heavily-glazed paper would be passed over. It is noteworthy, and should be suggestive to some of our workers in this branch, that in many cases the advertised article is not made prominent; its presence is unnoticed until the accompanying type matter has been read, when the advertising appeal becomes insistent by reason of its very reticence.

* * *

The Spotlight in the Studio. The exhibition of professional portraiture at the Congress of the P.P.A. last month, and also the portraits included in the Salon and Royal Photographic Society's show, have demonstrated the desirability of using some style of spotlight for obtaining special effects of lighting. The ordinary studio lighting, whether it be daylight or artificial light, falls short of the requirements in this direction, and only the more general effects may be obtained. It is quite possible to control all lighting in the studio, by means of shades or reflectors and by the position of lamps or windows, but the more appreciated effects are difficult, unless some special apparatus is to hand. The general form of spotlight now offered for studio use owes, perhaps, its success to the effects obtained by it in cinema work, but while these effects are largely of a theatrical kind, there is no doubt that in skilful hands this method of lighting can be extremely useful in the portrait studio. The spotlight, as now placed upon the market, consists of a metal body containing the electric lamp and reflector, mounted on a sliding tray. In front of this is placed a convex condenser, and by aid of the sliding tray the beam of light can be increased or decreased in covering power. A small spot can be focussed upon the object it is desired to illuminate, or a flood of light can be spread over a large area. The lamps are usually light in construction, and therefore very portable, and can thus be moved with a minimum of trouble to any part of the studio. Various diffusing devices are obtainable for use with these lamps, and colour filters may also be used to tone down the beam to any desired amount. This type of lamp is equally useful to the professional who relies only upon daylight, for by its aid accentuated lighting effects can

be obtained, and shadows, often difficult to illuminate by reflected light, can easily be made more luminous. Moreover, the price of most of these lamps is quite reasonable, and places the accessory within the reach of all.

* * *

Opaque Negatives. Some months ago we inspected an installation for making bromide enlargements, in which the ordinary glass or film negative was eliminated and replaced by a bromide paper negative "print" which had been copied from the original positive print. This was in its turn re-photographed to the desired size upon bromide paper, the final result being, of course, a positive. While it can hardly be expected that an equally good range of tones can be produced by this method when compared with the usual one of using a transparent negative, there are circumstances in which the idea might be profitably employed. Given a series of much under-exposed negatives, these, if free from fog, might be used for the production of prints on any scale without the labour involved in the plan usually recommended of bleaching with mercury so as to produce a positive image, and from that making an ordinary negative. It is, of course, understood that this procedure is only recommended for images which are too feeble to give a printing density by any of the usual methods of intensification.

* * *

The Lens Surface. Lenses are not cheap to buy, and extra rapid anastigmats are not the cheapest of lenses, hence it is rather surprising that so little thought is exercised over their preservation. Not a few good lenses are now suffering from that iridescent appearance upon their surfaces which is an indication that a slight corrosion of the glass has set in, a warning which, if not heeded, will result in a much more serious deterioration. We have noticed this to occur chiefly to lenses which are left permanently on the camera, as is the case with Press and many studio cameras; it is rarely seen upon a lens which is removed from the camera and put away in a case or bag. It is not wise to expose any lens to a damp atmosphere or to a strong light unnecessarily. Lenses which are left upon cameras should be fitted with closely-fitting caps, and in the case of studio lenses, both back and front lenses should be so protected. The temperature of most studios varies within a wide range during a day and night, especially in autumn and winter, and with these changes there is grave risk of moisture being condensed upon the glass. One night may do little harm, but a hundred nights will do much.

* * *

The Dark-Room Towel. Observations of a number of dark-room methods lead us to repeat some warning notes, which have already been given many times. We refer to carelessness over spilled solutions. Very often the same cloth is used to mop up spilled hypo and spilled developer, and then to wipe the photographer's fingers between operations. And, instead of being removed from the dark-room, washed and dried, the cloth is left hanging near the developing bench. When dry, it contains a deposit of tiny crystals left by the evaporated solutions, capable of floating into every cranny and crack of the dark-room. The cloth needs only to be picked up and put down again to start hundreds of these crystals on their ways into most unlikely places. These afterwards give rise to all sorts of markings on plates and papers, for which, very often, the manufacturers get the blame. Solutions spilled, however small the quantity, should never be given a chance to dry up; they should be thoroughly mopped up at once, and, when it is necessary to wipe the fingers, this should be done with something which does not contain a kind of cocktail of all the solutions used. Otherwise, faults due to contamination are sure to make their appearance.

PORTRAITURE IN A SITTING ROOM.

WHILE it continues most difficult to find premises suitable for portrait work, without paying an enormous rent or going to considerable expense in building or alterations, the young photographer who has finished his (or her) novitiate, and is anxious to make a start, or the old hand who wishes to open a branch in a new neighbourhood, is often deterred from taking premises in a desirable position by the fear that it will be impossible to do good work without something approaching an ordinary studio light. Curiously enough it is the man with studio experience who is most affected in this way. There are few rooms which have not enough light for portrait work. Twelve square feet of glass will suffice for most purposes if the room is large enough to permit of free movement of the camera and sitter. In such rooms it is not usually practicable to take full lengths by daylight, but nearly all bust and half-length work can be undertaken with success.

Not only the size and position of the window have to be considered, but the nature of the outside surroundings. Bushes, trees and other buildings if near a window may entirely destroy its value for portraiture, so that no room should be chosen before sitting in the positions which would be occupied by the model and noting the extent of unobscured sky which is visible.

There has lately been a considerable change in our ideas as to portrait lighting. In every exhibition may be seen photographs which outrage all the traditions of Victorian portraiture, and this has made it all the easier for the worker of to-day. One of the cardinal points was the avoidance of two sources of light. Now we have "spot lights" to light the sitter from the back in addition to the ordinary lighting. The worker in rooms need not therefore be hampered by any ideas of orthodoxy in this respect, but is free to seize any effect which may appear attractive in his eyes. Another tradition was that only one window in a room should be used to illuminate the sitter, others being completely blocked out. This, again, has gone by the board. Then, the great increase in plate speed which has been made in the last year or two has greatly simplified photography in ordinary rooms. Formerly it was necessary to work fairly close to the window to secure a reasonably short exposure. Now it is possible to work almost anywhere in a well-lighted room, if the lighting of the sitter be deemed satisfactory.

As the position of a window cannot be changed it is very necessary to provide as much free working space as possible, and to this end every article of furniture or piece of apparatus should be banished, so that the sitter and camera may be moved about easily and without fuss. The utility of this may be proved by taking half-a-dozen negatives of a sitter who does not change her position, the camera being kept at a fixed distance, but moved round in an arc of about ninety degrees, commencing with the lens axis parallel to the window and working round until the lens is pointing nearly into the light. Another set might be taken to show the effect of moving the sitter in a line parallel with the window so as to vary the amount of front and side light, the camera being kept stationary all the time. An experienced

photographer will hardly need to expose plates to realise the variations in lighting, but the beginner will find the exercise a useful one.

The reflector is an important accessory in room portraiture, and it is well to provide two, one five or six feet square, which can be used to give a soft general illumination when placed at a distance from the sitter, and a smaller one, about thirty by forty inches, which can be placed at close quarters for more decided effects. For "spot" light or jazz effects a small swing mirror is sometimes useful. This may be stood upon the floor or on a table and the light directed upon any desired point.

The apparatus for a room studio should be chosen with a view not only to the size of negatives to be produced, but the size of the room in which it is to be used. In most cases a whole-plate camera will be large enough, and unless the repeating back is a fetish it will be better to select the ordinary parallel bellows pattern with double slides. A studio stand is essential, on account of the facility of movement which it gives, but it should be no larger than is absolutely necessary. It is not wise to attempt to work with a solitary lens, particularly if it be of short focus. It is hardly safe to approach nearer to the sitter than five feet, for fear of what is improperly called distortion, and this being the case a sixteen-inch lens will be necessary for a three-inch head upon a whole plate, the distance for this size being sixty-four inches. Sixteen inches is obviously too long for smaller heads and sitting figures, so that another lens, which may have a focal length between nine and eleven inches, is necessary.

If the room studio has lofty windows, say nine or ten feet high, standing figures may be undertaken, but with lower ones it will be necessary to provide some form of artificial light. If current be available, two or three 500-watt gas-filled lamps may be fitted to serve as a top light, and all will be well. Where there is no current, an enclosed flash lamp may be used with advantage. Such lamps are usually fixed upon an adjustable stand so that the light may readily be placed at any desired height.

There is a tendency when working with a small area of light to get hard negatives, but with most rapid plates this may be avoided by curtailing the time of development. Nothing is gained by trying to bring out shadow detail, but much may be lost at the other end of the scale by blocking up high-lights.

WITH A PORTRAITIST IN THE STUDIO.

[The following article continues the notes by Mr. J. Effel on the part which psychology plays in the management of a studio. It is hoped to print some further papers by Mr. Effel. The next one, which should appear next week, will deal with accessories and backgrounds.]

VIII. *(continued)*—THE PSYCHOLOGICAL ASPECT.

There are some portrait photographers who seek to impress their customers by their dress and manner. There are others who do not mean it, but who certainly create impressions that are not pleasing. I must confess that I have found that the public do not care a hang about the photographer's appearance. Frock coat, velvet jacket, long hair may impress a certain class, but nothing counts so much as naturalness and sincerity. Remember it is always the quack in all professions who spends so much time and money in self-advertising. The "typical" photographer is becoming out of date. It goes without saying that the studio worker's manners should be perfect, and that he should have a knowledge of all the little courtesies and evidences of good breeding. I remember years ago being sent as locum to one of the highest class studios in the country. The operator was a pompous sort of chap with a "guid conceit o' himsel'," as they say in Scotland. I had to work with him for one day to get into the way of things before he left on holiday. The dressing-room was on the second, and the studio on the third floor. I found that it was the custom of this operator, when he had a particularly distinguished client, usually a lady of noble family, to bow her out of the dressing-room, and indicating the studio stairs with a fine sweep of his arm to *send the sitter up in front of him*. The humorous part of the business was that my reversal of the procedure threw the reception room into a panic. No doubt they are still acting like ill-bred flunkies at that studio, and the clients are having quiet chuckles at their expense. I am no great stickler for what is ordinarily called etiquette, but the point I wish to make in this connection is that at the very outset of the sitting it was more than likely that the client looked upon the artist as a bounder. And it does not need much psychology to tell us that that is a disastrous beginning.

Whether a photographer is treated with respect or with contumely depends altogether on the individual. I regret to say that the photographer has been sadly lacking in psychology in this respect. I can go over in my mind a dozen of successful photographers, every one of whom is a broad-minded, approachable man, with the social virtues one expects from a good business man and citizen. But there is also a very large class, good enough photographers, and men who could easily fill a better position, but who seem to spend all their spare time in grousing. What most of these grumblers need is Kickology. Just listen to this story for a minute. Mrs. Green has brought her four little children to be photographed by Snapshotte, who advertises himself as a "medalist (one I) for child portraiture." Mrs. Green has made no appointment, she arrives at quarter to one, and the light is bad. Old Snapshotte is in a deuce of a temper. He has been struggling with copies all morning, blaming everyone for losing originals, the paper stop of the copying lens has been torn, and no one can think where he put the scissors. The camera is dismantled of portrait lens, hood, vignetting arrangements, and sundry odd parts, and pulled out to its triple extension. Snappy (that's what the staff and everybody else call him) has just thought about running out for a bit of lunch, and now his receptionist has ushered these people into the dressing-room! The "medalist" is in a paroxysm. That fool, Jones, the general assistant went to his dinner (lunch?) at half-past twelve. Certainly that had been Snapshotte's own idea, but then when it was wet, and the copying not started—dash it all, he would give Jones a bit of his mind. The fellow had nothing in his head, no thought of anything but his dinner. And why didn't that stupid girl in the reception-room have a bit of tact? Why didn't she tell Mrs. Green that the light was too bad for children? It was high time those half-watt lamps were put back in their position; nothing seemed to be done unless he did it himself. Good heavens! there were the children actually wandering into the studio, when he wasn't anything like ready for them. Of

course if he *was* ready, they would take about a year to do up their hair! Mrs. Green has given no definite order; the children are all going to a garden-party, and she thought it a good opportunity when they were in their light clothes to have them photographed. Oh, maybe a group of four, then the two boys together, the two girls, and then some post-cards or cheaper ones of each one separately. The woman didn't seem to know her own mind at all, he would give the receptionist definite instructions that we could not do business in this easy-going fashion. True, he had told her, that when somebody well known came in, that it was better to leave it to his own discretion, and the Greens were wealthy people, and very easy to deal with, but, deuce take it all, look at the light, where has Jones put the screw that keeps the lens from falling out, and why didn't he tack up the Seavey background without waiting to be told? Assistants and customers were a lot of fools, and photography was a damned rotten business, if that woman thinks he can make pictures of her children—he had a good notion to give *her* a bit of his mind——

Now, that picture is not very much overdrawn. I would ask friend Snapshotte to cultivate a sense of proportion, to think how other businesses are conducted, and then ponder over the psychological aspect. In the big store a polite attendant shows customers to the different departments, courtesy is the rule, and on leaving you are asked if your requirements were satisfied. Is it any wonder that Mrs. Green and others of her class enjoy shopping, and dread a visit to the studio of such as our estimable friend, Snapshotte? Photography is a very exacting business, and one that is calculated to try the temper of a saint, but, after all, other folk have their troubles, yet keep their worries from their customers.

I would most certainly say that if the photographer is to give himself the best chance of success, he should establish himself on a friendly footing with the sitter in the first few minutes in the studio. Neither obsequiousness nor patronage will do. Unless a lady can feel quite at her ease and children happy in your premises, you will never be a success as a "portrait specialist." I have no room in my philosophy for the man who fawns and truckles to wealth and position, and treats his poorer clients with lordly condescension. I know that a photographer, like every other man who deals with the public, has to be "all things to all men," but adaptability is a very different thing from snobbishness. The man who makes a practice of leaving all but his richest clients to assistants should advertise the fact in his showcase. I was struck recently on reading an account of Horatio Bottomley's methods with audiences that in the finer perceptions, that otherwise astute showman was lacking in psychology. It appears that he had an elaborate system of grading his oratory according to the profit he was going to receive for his exertions. That was fundamentally unsound. I remember a comedian appearing at a concert where the hall was about a third full. When, after the show, I said something to the effect that the poor house did not seem to detract from his performance, he turned to me and said: "And do you think that I should punish those who *have* come to hear me, for the weather conditions which have kept others away?" Now, that's real psychology, and my actor friend stands high to-day as one who gives every audience his best. Why is Mrs. Smallpurse made to feel that she can only get the attention of an army trainee, when she orders half-a-dozen postcards of little Nellie? She knows jolly well that Snapshotte himself took those pretty pictures of kiddies which she admired in the window. And yet at the end of a bad half-year the Snapshottes will think to improve matters by sending out a few thousand circulars couched in terms of the most flagrant hypocrisy.

One does not require to be much of a character delineator to weigh up the various clients who enter the studio through the dressing-room—that is as far as pleasing with our work is concerned. The business man plainly dressed wants a different picture from the youthful knut, or, as I ought to put it, the smart young fellow should not be taken in a style suitable for a Pa. Roughly speaking, vulgar people want their clothes featured more than those who never wear anything but the best, but a photographer who cannot express admiration for a pretty frock or a tastily dressed child is a lost soul. The other day I came across a booklet sent out by a photographer of repute. It contained several pretty pictures of children, and almost implored patrons to have the little ones taken naked or with very little clothing. Ribbons and bows were to be avoided as inartistic, and the mother would be well advised to leave the arrangement in the capable hands of the man with such an array of awards for his child portraits). For downright folly, and faulty psychology this would be hard to beat. If a lady sends her child in hand-embroidered taffeta, with the latest in shoes and socks, she does not want a picture of a barefooted child in Jæger underwear. It is only the intimates of the family who have the privilege of seeing baby at bath time. Imagine the consternation at a fashionable "at home" if nurse introduced the children in combinations or less! Certainly, if a fond mother wishes to show the little one's beautiful body, that is a different matter, and the photographer should always be on the look-out for pretty, plump children, and can suggest tactfully a drapery picture to the parent. I question if many photographers could pass an examination in colours, fabrics and styles at present current in fashionable clothes. Crêpe-de-chine, sponge cloth, voile, stockingette, jade, rust, champagne, nigger convey nothing to the average male photographer. The same operator would carefully study some erudite treatise on the photographing of repoussé work, and yet not know the difference between a blouse and a jumper, nor bother his head for a second about suitable ways of taking the varying styles of the clients who keep him alive! There seems to be a sad lack of psychology here.

What the mere man must get into his head is that men's fashions may experience a complete change in fifty years, but those of women undergo revolutions in five years, and change from month to month, and what is more important, in these days of the cinema, *every factory lass or shop girl knows each change*. French photographers know more than we do in this respect. The man who fills his case with pictures of ladies in high-waisted robes with V-shaped necks when everybody is wearing frocks with boat-shaped neck, and waist line approaching the knees, will not get customers however "artistic" his work may be intrinsically. Don't tell me that positions are the same although the cut of the clothes is different, for that is not correct. The man who advertised "all the latest positions" was nearer the mark, for the student of dress will know that a lady in crinoline and one in a hobble skirt are different propositions in posing. Our grandmothers did not sit cross legged, but then that attitude would have been as awkward as it would have been thought unbecoming. Yes, let us scrap all out of date specimens, and have the courage of our convictions at the same time, and scrap our out of date ideas.

In conclusion, I would say that it is the business of a photographer to give the public what they want, not what he thinks they ought to get. If he thinks that a certain style or finish, although somewhat different from that which they are accustomed to, would better suit their taste, it is up to him to educate the public; but, after all, a professional photographer is a merchant, not a teacher; besides, it is generally the other way about, for most times it is the artist who will not change enough to suit the public.

Before we can supply our customers with the right goods, and serve them up in the right fashion, a pretty good study of their education, their social position, their artistic tendencies or their ostentatious bearing, is required. No rules can be laid down, but assuredly there is scope for psychology.

J. Effel.

DEPTH OF TONE IN PRINTS.

That the range of gradation of most classes of photographic papers is too limited is evidenced by recent introductions of slow gaslight papers for giving warm black tones, since the makers claim a longer scale of gradation than is found in the other development papers of their manufacture. Though these papers undoubtedly represent a step in the right direction, they are slow, and are not adapted for enlargement purposes except by the large trade firms who have very powerful light installations for dealing with this class of work. It may therefore be useful to examine various methods which may be used for increasing depth in the shadows. Though few of these are commercial, they may have special application in individual cases, it being obvious that any possible increase in scale must start at the point where the shadows begin to be blocked up.

Whatever the merits of the best development papers, it will probably be agreed that a carbon print is unsurpassed for the length of scale it will give, and it may therefore be regarded as the standard. It is, of course, necessary that the carbon print be made on a suitable transfer paper, and it will then be noticed that the depth in the shadows is enhanced by the semi-glossy appearance, due to the deposit of pigment embedded in a considerable amount of gelatine. Those tissues which give a dead matt result have far more pigment in their composition, and though useful in some circumstances, do not exhibit the special feature mentioned and so fall below the standard.

The writer has found that the maximum depth he can get with a carbon print is obtained, when using for the transfer paper, a smooth baryta-coated paper, such as is prepared for some bromide emulsions. The shadows of a good carbon on this paper are quite glossy, and the surface of the high lights is almost matt. Such transfer paper is not obtainable commercially, and it is not easy to prepare without leaving streaks in the coating of insoluble gelatine. Several applications of a weaker solution of chromé alum and gelatine than is usual in preparing transfer papers, is the best method of avoiding these markings.

With development papers various devices have been suggested to prevent the blocked-up shadows which are often apparent in a print which has been fully developed, and generally speaking, it is the platino matt type of paper which exhibits this defect in the most marked degree. Especially is this the case with sulphide-toned prints in this class of paper. The most common method of alleviating this trouble is to rub in an encaustic paste or megilp evenly over the whole surface. Some improvement is certainly effected by this means. A thin spirit varnish applied with care gives similar results, but in both cases the print is apt to show a somewhat greasy appearance. Steaming the print till the gelatine is on the point of melting used to be popular some years ago.

A print which has had a slightly too short exposure, and has been developed to the limit without blocking up the shadows is often much improved by intensification with the well-known bichromate formula, and the writer has recently seen some prints, exhibiting remarkable depth in the mixed chloride and bromide type of paper, which have been treated in this manner, and steamed subsequently until the surface shows a slight gloss.

In a recent number of this journal mention was made of the device of coating the print with an oil pigment which matched the silver image in colour, and removing this coating where accents were required. This procedure is very popular with some pictorial workers, and undoubtedly depth can be enhanced in this way. It would appear, however, that this pigmenting method is more often used to lower the key of the picture than to increase depth, though there is no particular reason why it should be so used, except to satisfy the aspirations of the particular worker.

All the devices mentioned so far, either require the general treatment of the print, or a certain amount of skill in selecting and treating portions of the print in a manner which will not be obvious on inspection.

The methods which follow depend more on photographic than mechanical processes, and in the writer's opinion, include the most effective means of giving depth to the shadows.

The print may be coated with a thin solution of bichromated gelatine; when this coating has been dried in the dark, the print is adjusted in proper register with the negative, and exposed to daylight for a sufficient time to render the gelatine in the shadows insoluble. The soluble gelatine is then washed off in hot water, leaving a deposit in those parts of the print where the light action has been sufficient. When dry, the gelatinised portions, *i.e.* the shadows, will dry with some gloss, while the high lights remain matt.

This method, while quite effective, is limited to contact prints. The same effect can be obtained on any bromide print by the Carbro process. Presumably double transfer paper would be suitable, though the writer has used photo-litho paper, in which the gelatine is more soluble, with complete success. This paper is treated exactly as a piece of pigment plaster would be for the Carbro process, and after fifteen minutes contact with the bromide print the two are placed in water at about 90 deg. F., the photo-litho backing peeled off, and the print developed as usual. On drying, a considerable amount of gelatine will be deposited in the shadows and none in the high lights, and the amount of the deposit can be controlled to a considerable extent by the time of immersion in the No. 2 bath and by the temperature of the water.

The results by this means are distinctly good and an obvious extension of the method is to use a piece of ordinary carbon tissue which will give a coloured deposit, and when the underlying bromide is re-developed the two images will give a print of great depth. Of course the bromide print must not be too dark or the final result will be very heavy, and it is important that the pigment chosen should bear some resemblance to the colour of the bromide print, or double tones may result in the high lights, if the pigment is completely washed away and the silver image re-developed. It is not always easy to avoid the high lights being slightly veiled, however, when the two images are superimposed.

Another method which involves considerable trouble, but is very effective, is to make the original print on a brand of paper suitable for Bromoil. After bleaching in the usual way the print is not fixed out, but is re-developed, and after a brief washing, is treated as if for Bromoil by pigmenting those parts which require strengthening, leaving the other portions of the print alone.

It is, of course, obvious that the pigment used must match the colour of the print, and the portions which have been pigmented should be finished with a fine brush, if necessary slightly moistened with petrol, to eliminate the grain. Any parts which has received unwanted pigment can easily be cleaned with rubber when the print is quite dry. Granted the necessary skill to pigment without showing obvious grain, there are great possibilities in this procedure.

A. H. Hall.

The City Sale and Exchange, of 81, Aldersgate Street, London, E.C.1, send us their sale catalogue of photographic apparatus. The sale is open until October 31, and some remarkable bargains are offered. Lenses, suitable for portrait work, are a special feature, while many types of cameras for field or studio are offered at very favourable prices.

THE ALKALIES IN DEVELOPMENT.

[In a recent issue of "American Photography" Mr. E. J. Wall has the following paper, in which is considered the action of the various alkalies in development from a standpoint which is largely neglected, namely, that of the relationship of the alkali to the chemical properties of the particular developing agent. The present paper explains the function of the alkali in a developer in a way which can be readily understood even by those with a very moderate acquaintance with chemical matters.]

Probably few recognise that alkaline development was discovered sixty years ago, more than twenty years before the first gelatine dry plate was made, and that pyro-ammonia was used. This was a great advance over the old acid developers and it differs entirely in its action. With the old iron or pyro-plus-silver developers, we had what is called physical development, in which, practically, the light-affected silver salts were not in themselves reduced, but merely acted as germs or nuclei for the deposition of the nascent metallic silver of the developer, which was deposited on the top of the film. With alkaline developers, the light-struck silver salt is itself reduced and the image is formed in the thickness of the vehicle, there being no free silver nitrate or other salt to form the nascent silver.

It is not going too far to ascribe some of the merit of the discovery of the alkaline developers to an American, E. Anthony, of the well-known firm E. and H. T. Anthony, the predecessors of the Ansco Co. He stated in 1861, that the speed of a bath collodion plate could be increased by fuming it with ammonia prior to exposure. Then Wardley suggested the use of a neutral solution of pyrogallol, and Leahy and Russell almost simultaneously discovered the action of alkaline pyro, which could have been a logical outcome of Anthony's suggestion.

At the present time one may say that, with the exception of amidol, and like developing agents, an acid developer is never used, and probably even with these the hydrolysis of the sulphite, which is always used with them, furnishes the sodium to form the phenolates that are the actual reducing agents.

Unfortunately we are accustomed to use the term "developer" not only for the real reducing agent, but also for the solutions as a whole, which sometimes leads to a little confusion or doubt.

As a legacy from the early days of the dry collodion plate and collodion emulsion, ammonia was the first alkali used, and though it persisted for many years, it has now fallen into almost complete disuse, except with colour screen-plates, so that it is not worth while to discuss it. Its disrepute is founded on the fact that it is very volatile and therefore the developer is constantly changing, and to the fact that but very few experiments have been recorded of the use of ammonia with the newer developing agents, in which we may include every one except pyrogallol.

Of the fixed alkalies we have the carbonates and the hydroxides, usually called the caustics, of potassium and sodium. It may be as well to try and give a sketch of the part played by the alkali in development, and this may be briefly represented by the following equation :—

$$2AgBr+2Na_2CO_3+H_2O=2Ag+2NaBr+2NaHCO_3+O$$

Or putting this into words, the bromine set free from the exposed silver bromide combines with some of the sodium carbonate to form sodium bromide and sodium bicarbonate, which are restrainers, while oxygen is set free, this molecule of oxygen being taken up by the developing agent. If this last reaction does not take place there is no development, for it is the capacity of the developing agent for oxidation that starts the reduction of the silver, and the alkalies accelerate the action.

The carbonates are the most generally used salts, and it is generally assumed that the potassium carbonate gives greater density than the corresponding sodium salt. Actually it gives a little more rapid development. It has fallen into considerable disuse because of its higher price and its proneness to deliquesce, or absorb water from the air. The sodium carbonate is the more generally used.

There are actually three carbonates of sodium; the bicarbonate or acid carbonate, $NaHCO_3$, the sesquicarbonate, $Na_2CO_3.2NaHCO_3.3H_2O$, both of which are practically useless for development, and the normal sodium carbonate. This is the salt actually used and it exists in three forms: the crystalline, or decahydrate, $Na_2CO_3.10\ H_2O$, the monohydrate $Na_2CO_3.H_2O$, and the anhydrous salt Na_2CO_3.

If we place under these formulæ their molecular weights we shall easily see what relation they bear to one another :—

$Na_2(CO_3).(10H_2O)$
$46+60+180=286$
$Na_2(CO_3).(H_2O)$
$46+60+18=124$
$Na_2(CO_3)$
$46+60=106$

Therefore, it is clear that if we use the crystalline salt, we are actually paying for and using nearly two-thirds of water.

In most formulae we meet with the term "anhydrous," whereas as a matter of fact the true anhydrous salt is rarely used, the photographic desiccated soda being the monohydrate. It is generally assumed, too, that this is double the strength of the crystalline salt, but actually it is stronger, in the ratio 286 : 124, or 100 : 43.4. But we shall not make a very grave error if we assume that the desiccated soda is double the strength. For instance, taking a typical developer containing 5 per cent. of crystallised carbonate; it contains approximately 25 grains per ounce of solution. Then, if we use half the quantity of the dry salt, the error will be under 2 grains per ounce. This excess is negligible and may well be within the error of weighing.

The dry salt has the advantage over the crystalline, besides not taking up so much room, of being more stable, as it is not so likely to effloresce, or lose its water of crystallisation. It should be noted that commercial carbonate, if not properly kept, almost always contains some of the bicarbonate, as it absorbs carbon dioxide from the air along with moisture. After thirteen days exposure to the air it may contain as much as 15 to 20 per cent. of bicarbonate, which is useless for developing. It is obvious, also, that the crystalline salt is much more prone to this decomposition than the desiccated, because of its richness in water (H. Dubovitz, "Chem. Ztg.," 1921, *45*, 890).

The quantity of carbonate to be used with a given developer varies considerably according to the predilections of the worker, or writer, and variations within reason make no essential difference, save in the velocity of development. One may, of course, adopt the formula suggested by the plate maker, and it is always assumed, and sometimes claimed, that these are the best suited to the plates. But as someone once said: "A maker's formula generally shows the maximum amount of alkali and the minimum amount of restrainer, or, in other words, is the most trying developer that it is advisable to employ, or that the maker will guarantee his plate to bear."

The more alkali used the more rapid the development, and the shorter the total time of development. Increase of alkali cannot bring out more detail than the exposure has put into the plate. The only advantage in the larger amounts of alkali is that they develop out the fainter details in the shadows more quickly, so that one may stop development before the highest lights have become too dense to be properly rendered in a print.

W. F. A. Ermen has recently shown ("Phot. Journ., 1922, 62, 123) that, except in the case of hydroquinone, increase of carbonate of soda above N-5, that is about 1 per cent of the anhydrous salt, does not affect either the time of appearance or the density. As the time of appearance of the image is a practical measurement of the velocity and duration of development, it is obvious that if we use more than the above quantity we are merely wasting it and probably causing a greater tendency to fog.

The caustic alkalis, the hydroxides of potassium and sodium, are not so much used, except with some of the newer developers, mainly because they are supposed to cause frilling, cause more fog, and attack the fingers. As a matter of fact they can be used with excellent results, provided they are used properly. Their action with the developing agents is to form salts, the so-called phenolates, and this is well shown in the case of pyrogallol. The formula for this is $C_6H_3.OH.OH.OH.$, and it is possible to replace the H (hydrogen) of the three OH molecules with either potassium or sodium. Then we have:—

$C_6H_3.OH.OH.ONa$, the monophenolate,
$C_6H_3.OH.ONa.ONa$, the diphenolate,
$C_6H_3.ONa.ONa.ONa$, the triphenolate.

The last of these compounds, the triphenolate, is so energetic that it will reduce unexposed silver bromide at once; that is, it fogs the plate all over at once. The diphenolate is not quite so energetic and begins to reduce the image, but in about 2 minutes it also fogs the plate. The monophenolate gives no more fog than the carbonate, yet develops more quickly and actually converts the pyro developer into one that is more like metol than anything else.

It is easy to calculate how much of either of the caustic alkalis is required to form the monophenolate. Taking the molecular weight of pyrogallol, so often called pyrogallic acid, though it is not an acid, as 126, we only want to add one molecule of soda (NaOH = 40) or potash (KOH = 56) to the above quantity, according to the following equation:—

$$C_6H_3.OH.OH.OH + NaOH = C_6H_3.OH.OH.ONa + H_2O$$

Putting the above facts into a formula we arrive at the following:—

A. Pyrogallol	... ...	25 gms.	192 grs.
Sodium sulphite, dry	...	82 gms.	630 grs.
Water	... ...	1000 c.c.s	16 ozs.
B. Caustic potash	...	11.5 gms.	88 grs.
or caustic soda	... ...	8.5 gms.	65 grs.
Water	... ...	1000 c.c.s	16 ozs.

For use mix 1 part of A, 1 part of B and 1 part water. This gives normal density in from 2½ to 3 minutes, and a good black image with practically no trace of fog. This was suggested by E. Valenta ("Phot. Korr.," 1902, *83*, 703), and worked out on the above argument.

Some may consider that, as practical workers, there is very little interest in such facts as these, and that the equations are put in to look learned. But suppose we apply them to a particular case, and for this purpose take the article of Mr. J. J. Proskauer ("American Photography," 1922, 242). In the first place, I should personally find fault with the formula, because it leaves me in doubt whether the total bulk of the solutions is to be 72, 32 and 12 respectively, or whether the salts have to be added to these quantities of water, when the volume of each solution would be an unknown quantity, on which exact arguments cannot be based. Mr. Proskauer has probably given the formula as he received it. It is:—

A. Distilled water	... ...	72 ozs.
Sodium sulphite (E.K. tested)	...	6 ozs.
Hydroquinone (E.K. tested)	... ...	3 ozs.
Potassium ferrocyanide	... ...	16 ozs.
B. Distilled water	... ...	32 ozs.
Sodium sulphite	... ...	3 ozs.
Potassium ferrocyanide	... ...	8 ozs.
C. Distilled water	... ...	12 ozs.
Sodium hydroxide	... ...	6 ozs.

To use, take four parts A, two parts B and one part C.

As the caustic alkalis form the phenolates, and the formula of hydroquinone is $C_6H_4OH.OH.$, it is clear that caustic soda may form either the monophenolate or diphenolate, according to the quantity used. Assume the molecular weight of hydroquinone to be 110, thus:—

$$C_6H_4OH.OH.$$
$$72+4+17+17=110$$

Then the monophenolate is formed with 40, the molecular weight of the soda, and the diphenolate with 80.

Now to apply these facts to the formula. Assuming the total bulk of A and C to be 72 and 12 respectively (B does not interest us at all in this calculation), then it is obvious that as they have to be mixed in the ratio of 4:1 there will be 73 grains of hydroquinone, and this must require 53 of caustic soda to form the di-salt. But there were actually used 219 grains. That is 3½ times too much, or an excess of 166 grains in the 5 ounces of mixture, or taking into consideration now the B solution, there were 23.7 grains of caustic extra per ounce, which can do no good except blacken the plate.

If the quantity of soda in this formula be reduced one ought to have an equally active developer, with far less tendency to fog. Incidentally, let it be remarked that the use of potassium ferrocyanide in conjunction with a caustic alkali and hydroquinone was suggested by G. Balagny in 1891 ("Phot. Archiv.," 1891, 10) and A. Lainer ("Phot. Korr.," 1891, *28*, 6), and the latter's formula was for many years a favourite in Europe. The "Les-Lite" formula is merely a botched-up Lainer formula.

Should one want to use one or other of the salts, the following brief table shows the equivalent weights that should be used:—

NaOH	KOH	Na_2CO_3	$Na_2CO_3.H_2O$	$Na_2CO_3.10H_2O$	K_2CO_3
80	112	106	124	286	138
1	1.400	1.325	1.550	3.575	1.725
0.714	1.	0.946	1.110	2.553	1.232
0.755	1.033	1	1.170	2.698	1.302
0.323	0.452	0.858	1	2.307	1.113
0.280	0.392	0.371	0.433	1	0.483
0.580	0.812	0.768	0.899	2.072	1

To use this table it is only necessary to multiply the weight of a given alkali by the figure to that which it is desired to use; thus 5 of anhydrous soda are obviously equal to 1.170×5 of the monohydrate.

There is one action of the alkalis with developing agents, which are combined with acid radicles in order to increase their solubility in water, that should not be overlooked, and that is that the free base is precipitated on the addition of small quantities of the alkali. This is particularly noticeable with paramidophenol hydrochloride, $C_6H_4.OH.NH_2.HCl$; the action of the first addition of an alkali is to combine with the hydrochloric acid, setting free the base, which is not very soluble in water, and only on the addition of further alkali does it go into solution. The developing agents which show this property more or less are adurol (brom or chlor-hydroquinone), diamidoresorcin hydrochlorate, metol, ortol, paraphenylendiamine hydrochlorate and triamidophenol hydrochlorate; though with most of these, unless a fairly strong solution be used, the precipitate passes unnoticed. Naturally one has in these cases the chloride or sulphate of the alkali formed, and the former acts as a restrainer in developing.

Besides the above alkalis there are a few other agents that have been suggested, but which have not come into general use. Sodium tribasic phosphate, $Na_3PO_4.12H_2O$, was suggested by Lumière ("Jahrbuch," 1896, *10*, 190) on the ground that it gave greater density without attacking the gelatine or causing fog. However, this hydrolyses, on solution in water, into the normal or di-sodium phosphate Na_2HPO_4 and caustic soda NaOH:—

$$Na_3PO_4.12H_2O + H_2O = Na_2HPO_4.12H_2O + NaOH$$
$$380 \qquad\qquad 358 \qquad\qquad 40$$

It is therefore obvious that we only have to mix the normal phosphate and caustic in the weights given under the equation to form the same thing.

Acetone, $CH_3.CO.CH_3$, a characteristically smelling colourless liquid, produced by the dry distillation of acetates, was also recommended by Lumière and Seyewetz for use with those reducing agents capable of forming the phenolates. Its first action is to combine with the sulphite of the developing solution and form acetone sulphite, with the setting free of the sodium which combines to form the phenolates, as in the case of hydroquinone thus:—

$$2CH_3.CO.CH_3+2Na_2SO_3+C_6H_4.OH.OH.=$$
$$2(CH_3.CO.CH_2.NaHSO_3)+C_6H_4.ONa.ONa$$

This has not come into general use, and its only virtue would seem to be that it costs a little more; it works fairly free from fog, does not stain much, and does not soften the gelatine.

The only other compound we need consider is formaldehyde, again suggested by Lumière and Seyewetz ("Jahrbuch," 1898, *12*, 419), its action being comparable to that of acetone. The only developer that may be considered as having come into any use at all with this is the following:—

Hydroquinone	16 gms.	123 grs.
Sodium sulphite, dry ...	80 gms.	614 grs.
Formaldehyde	20 c.c.s	154 minims
Water	1000 c.c.s	16 ozs.

This is an extremely useful developer for making negatives of black and white line drawings and diagrams, as it gives, on photo-mechanical plates, extreme contrasts with clean whites.

The lithium compounds and a few other isolated agents have been suggested, but in the first case the price and insolubility of the lithium salts are against their general adoption, and in the other cases the substances would seem to have been suggested for the sake of spending more money or as merely something for someone to write about.

E. J. Wall.

REAL CAUSES OF BLISTERS.

In the current issue of "Studio Light," the monthly magazine for professional photographers issued only in the United States by the Eastman Kodak Co., are the following notes on the causes and preventives of blisters in prints:—

Blisters on prints are seldom due to any fault in manufacture of papers, but they may be produced on any gelatine paper by improper manipulation. The best way to prevent blisters is to understand their causes—the remedies then become obvious.

Blisters may form on prints during developing, fixing, washing or toning, or partly during either operation. Their formation during development is a rare occurrence. The same is true of fixing, unless the print is transferred direct from a strongly alkaline developer to a strongly acid short stop bath or fixing solution, in which case small bubbles of gas are formed within the gelatine film because of the action of the acid on the alkaline carbonate. The formation of gas in the gelatine is over the entire surface of the print. If for any reason the gelatine film has become softened, a small gas balloon is formed under each weak spot where gas is being liberated, resulting in blisters or so-called air bells. If the developer is not too alkaline or the acid short stop or fixing bath is not too acid, and prints are rinsed after developing, such blisters are not formed.

Air bells or blisters are liable to occur if the water used for washing contains an excess of dissolved air. Water under high pressure is usually the cause of the trouble. The water contains a great amount of dissolved air and the gelatine emulsion is saturated with water. If the temperature of the water is slightly raised, this air is expelled with the result that it may raise the gelatine and form an air bell. If the gelatine has been properly hardened the air bells are not so likely to form. If this trouble is a persistent one, the remedy would be an open tank into which the water could be drawn from the tap. This relieves the pressure and allows the air to escape.

All blisters, however, are not gas or air blisters. They are often filled with liquid, in which case they are caused by the phenomenon of osmosis.

If a solution of a salt such as hypo is inclosed within the gelatine film of a print and the print is immersed in water, there is a tendency for the water to penetrate the film at a greater rate than the hypo solution diffuses out. An internal pressure is thus created within the gelatine (and especially at the point of contact of the gelatine film and the paper support) which is known as the osmotic pressure of the hypo.

If by any means, therefore, the adhesion of the film and paper in any particular spot has become weakened, or if by swelling or softening or for any other reason the gelatine has become less porous in one spot than in another, the water will penetrate the gelatine film faster at that spot than the hypo diffuses out, with the result that a blister will form.

This osmotic pressure is often great enough to break the gelatine film. If the gelatine has been properly hardened and the print carefully handled, the gelatine should be uniformly porous and no such trouble experienced.

Most blisters are formed during washing after fixing, and their production is assisted by the presence of cracks, creases, or folds in the paper, since wherever these occur the gelatine film is likely to be broken away from the paper support.

Likewise, any factor in manipulation which tends to soften the gelatine locally tends to produce blisters. A powerful spray of water will soften the gelatine in the spot where it strikes the print, and touching the print with warm fingers will soften the print at the point of contact.

Washing at high temperatures should be avoided as much as possible, and in all cases the temperature of the various solutions should be maintained as nearly the same as possible. A frequent cause of blisters is the transference of prints from a warm fixing bath to cold water, and vice versa. In cold weather keep a fixing bath where it will be as cold as the water used for washing.

Apart from the effect of temperature, the use of alkaline wash water or an alkaline fixing bath, caused by carrying developer into the fixing bath with the prints, will tend to soften the gelatine and produce a condition favourable to blisters. It is important then to maintain the acidity of the fixing bath, or use a fresh bath at all times.

Blisters formed during after-treatment are usually caused by toning, and may be due to insufficient hardening, the use of one of the acid bleaching baths, an excessively strong sulphiding bath or too hot a hypo-alum bath, together with one or all of the above causes. If a print is not thoroughly hardened and is placed in a very hot hypo-alum toning bath, it will soften before the alum can begin its hardening action.

If, during final washing, it is seen that blisters have formed, the paper underneath may be pricked and the water squeezed out, or the print may be immersed in equal parts of water and alcohol, followed by a bath of alcohol alone. It is better, however, to prevent toning blisters by drying prints before toning, or better still, by treating with a 3 per cent. solution of formaline after washing and before toning, with or without drying, if there is any reason to believe prints may not be sufficiently hardened to withstand toning.

Assistants' Notes.

Notes by and for assistants will be considered for this column. Payment for accepted contributions is made on the first of the month following publication.

Small Workroom Economies.

In every photographic workroom there are ways—too many to count—in which small savings can be made in time or material.

In some cases, of course, a supposed economy may be only a matter of "penny wise and pound foolish." One man I knew served out some cheap draper's wadding to his assistant instead of the pure cotton wool generally employed for swabbing off negatives. The result was a batch of negatives so scratched that the extra work involved cost, in assistants' time alone, enough to pay for several years' supply of cotton wool.

As a matter of fact, a piece of medicated gauze, well washed and kept in a pot of water, has been found as effective as the best cotton wool without leaving any fluff on a corner of the plate. One piece costing a few pence will last many months in constant use, and so represents a real saving.

For local reduction and the like a little cotton wool is essential. Instead of leaving the roll about to get dusty, it is best to keep it in a box, of which the lid is towards one as it stands on the

shelf. The lower portion of the lid is removed entirely. Thus it is easy to pull out a small bit instantly as required while keeping the bulk clean.

Speaking of reduction, I have seen many dark-rooms where hypo and ferricyanide are just dissolved whenever required for use. This is just one of those innumerable things that are said to "only take a minute." This is a wasteful method, because not only is far too much of the chemical usually taken for the job in hand, but the newly-dissolved hypo is cold, so that the reducer is almost inert, and still more of the ferricyanide is added to overcome the tardy action.

As to the time taken, it is a very interesting experiment actually to take a record of the time occupied in making up these scratch solutions and then to reckon the actual cost of each of these operations in terms of the assistants' wages. Taking, for example, a Winchester of hypo saturated solution and a pint of potass ferricyanide of similar strength, it is fairly safe to say that the time taken to make them up is scarcely more than that required for one of the ordinary doses, provided one has hot water and reasonable facilities for making up such solutions.

In one studio I noticed a gas boiling ring used for heating the mounting-irons. It did not seem so obvious to the proprietor as it did to everyone else that the cost of the gas wasted in a quarter was more than that of a special small burner several times over. In another place I was struck by gas burners being kept alight all day. Although it was a busy shop and kettles of hot water were in fairly frequent demand, as well as batches of dry-mounting, it appeared that there were equally frequent, and sometimes long, intervals when nothing of the kind was wanted.

It was some little time before the reason for this waste came to light. It appeared that the assistant in charge had expended some small out-of-pockets among which was a dozen matches. On applying to the firm's cashier, he was referred to the secretary, a person of rather forbidding manner, who hum'd and ha'd rather unnecessarily over the trumpery expenditure. As the assistant in question disliked such painful interviews, he was faced with the alternatives of providing the firm with matches (amongst other small items) out of his own pocket, or of keeping a burner going all day. The fact of his being a non-smoker decided his taking the latter course.

The supply of spotting brushes seems to be a sore point with some people. It does not seem to be realised that the constant friction of the bristles upon paper, etc., wears them away, so that a brush cannot keep its point for ever.

In fact, the best of brushes has a limit to the work it will do before the point has gone. Now, there are two factors to consider. A brush that has not a good point makes spotting harder and far slower in the doing so that the time lost is soon worth more than a new brush. Then it should be known that a second-rate brush after a week's use is hardly better than a worn-out good one. In spotting brushes a few pence more for the best possible save, in the long run, many hours of niggling work.—D. C.

Photo-Mechanical Notes.

Chromate-Sensitised Resin.

A process which has the appearance of being a new departure in bichromate printing is the subject of a patent specification, No. 183,817, applied for by E. Doelker, of 48, Militär Strasse, Zürich, under the International Convention, but not yet accepted.

A layer of natural or artificial resin is sensitised with a chromate, and is exposed under a negative until the portions exposed are rendered insoluble in a developer comprising (1) an alkali or a substance having an alkaline reaction, or (2) alcohol or other organic solvent, with or without the addition of alkaline substances. The light-sensitiveness of the layer may be increased by adding (1) carbon disulphide, either pure or containing sulphur, or (2) albumen decomposition products. Numerous examples of resins, sensitisers and developers are given.

In one example of the process, 50 to 200 gms. of a non-sticky artificial resin, for example a condensation product of phenol and formaldehyde, are dissolved in 1,000 cc. of alcohol coloured with Schweinfurt green. 100 to 250 cc. of this solution are agitated for 1 to 5 minutes with 2 to 10 gms. of ammonium bichromate and filtered through cotton-wool. A polished zinc plate is roughened with a solution containing nitric acid and alum, rinsed, dried and warmed. The resin solution is then applied to the plate, exposure under a line or screen negative is made in sunlight for three to five minutes, and development effected with a 1 to 1.5 per cent. solution of caustic potash. The plate is rinsed, dried and warmed, and the resulting reproduction etched in fairly strong acid.

Alternatively, an exposure three or four times as long is given, and development effected with a mixture of equal parts of alcohol and glycerine. In another example an alcoholic solution of shellac is similarly employed. The sensitiveness of the resin layer may be increased by adding to it (1) 15 per cent. of carbon disulphide, or (2) 10 per cent. of a solution of albumen obtained by boiling 1 part of maize or wheat with 10 parts of alcohol under a reflux condenser for several hours. After development the backing material may be etched, or the developed layer may be used for direct printing. The process is said to be suitable for all photographic reproduction on non-absorbent backings in monochrome and polychrome printing, and for lithography.

Collodion and Silver Nitrate Consumption.

An operator who compounds his own collodion has many advantages over one who uses a commercial collodion, for, knowing the ingredients and their quantities he is able to calculate the amount of silver nitrate abstracted, and also the amount of by-products left in the bath by the chemical reaction set up by the formation of the sensitive silver haloid.

How this can be done may be explained as follows: Take a winchester of collodion "iodized" with :—

Zinc iodide	320 grs.
Lithium chloride	60 ,,

Here we have 380 grs. of haloid requiring for conversion to silver haloids 580.8 grs., producing 673.92 silver haloids and 286.88 of by-products, i.e., nitrates of zinc and lithium. Each ounce of collodion sensitised as above will contain 4.5 grs. of halogens and consume 7.26 grs. of silver nitrate, leaving in the bath 3.586 grs. of by-products. At the end of the day's negative-making, if a note is made of the quantity of collodion used, the amount of silver nitrate, taken out of the bath may be calculated and replaced. Assuming that 9 ozs. of collodion has been used, then the addition of 90 grs. of silver nitrate will compensate for the abstraction of silver nitrate, by the formation of the sensitive silver haloid and for that which has clung to the film, i.e., if the plates have been well drained after taken from the bath, if not, then 100 grs. will be needed

When such a course of procedure is followed and kept up, the silver bath will keep in good condition and give better and more uniform negatives than when the bath is worked till it gives out from sheer exhaustion.

In addition to keeping the silver nitrate up to its normal strength, the operator is able to note the gradual accumulation of the by-products, which, when in a small quantity, are no doubt of great use, but there must be a limit to the usefulness of these alien nitrates, and if these accumulations have been noted the limit of their usefulness can also be determined.

With line negatives the limit of these alien nitrates is much higher than when screen negatives are wanted, the solidity of the fine dots being much influenced if these nitrates are in excess.

Operators using other haloids than those given above may be interested to know how the above figures are obtained. This is just a simple equation. Divide the molecular weight of silver nitrate by that of the halogen. Thus taking ammonium iodide as the halogen,

Silver nitrate	$AgNO_3$	170	
Ammonium iodide	NH_4I	145	= 1.172

showing that each grain of ammonium iodide requires 1.172 grs. of silver nitrate for full conversion to silver iodide. Bromides and chlorides may be calculated in the same way.

When the base is a bivalent, then two molecules of silver nitrate are required, producing two molecules of silver haloid, and one molecule of nitrate thus :—

$$\frac{2AgNO_3}{ZnI_2} \quad \frac{340}{319} = 1.066 \qquad \frac{2AgBr}{ZnI_2} \quad 1.473 \text{ and } \frac{Zn(NO_3)_2}{ZnI_2} = .592$$

W. T. Wilkinson.

FORTHCOMING EXHIBITIONS.

October 18 to 21.—Rotherham Photographic Society, Hon. Secretary, S. G. Liversidge, Orissa, Gerard Road, Rotherham.

October 18 to 28.—Portsmouth Camera Club. Particulars from the Hon. Secretary, C. C. Davies, 25, Stubbington Avenue, North End, Portsmouth.

November 4 to 11.—Bournemouth Camera Club. Particulars from the Hon. Secretary, 88, Old Christchurch Road, Bournemouth.

December 9 to 31.—Rochdale Amateur Photographic Society. Particulars from the Hon. Secretary, W. Lord, 10, Derwent Street, Rochdale.

1923.

February 5 to March 3.—Northern Photographic Exhibition, City Art Gallery, Manchester. Latest date for entries, January 12. Particulars from the Hon. Exhibition Secretary, Walter Johnson, 30, Hartington Road, Chorlton-cum-Hardy, Manchester.

March 2 to 31.—Pittsburgh Salon of Photography. Latest date, February 5. Secretary, Charles K. Archer, 1,412, Carnegie Building, Pittsburgh, Pa., U.S.A.

March 13 to 16.—Exeter and West of England Photographic Exhibition. Particulars from the Hon. Secretary, Frederic G. Tutton, 9, Union Road, Pennsylvania, Exeter.

March 16 to 24.—Photographic Fair, Holland Park Hall. Secretary, Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications September 25 to 30.

DAYLIGHT DEVELOPMENT.—No. 26,225. Manufacture of negatives from roll-films in daylight. H. J. J. van den Boogaart.

SHUTTER DEVICE.—No. 25,865. Electro-mechanical starting and stopping device for photographic shutters, etc. C. P. Lingwood and C. G. Lowen.

PHOTO-MICROGRAPHY.—No. 25,927. Apparatus for taking low-power photo-micrographs. H. G. Butterfield.

APPARATUS.—No. 25,959.—Apparatus for discovery and correction of astigmatism. R. V. Greene.

TELEGRAPHIC TRANSMISSION OF PHOTOGRAPHS.—No. 26,085. Method of telegraphing photographs. T. T. Baker.

CINEMATOGRAPHY.—No. 26,204. Method of producing a natural effect in projected pictures. T. H. Marten.

CINEMATOGRAPHY.—No. 26,034. Cinematograph screen. A. J. Vickery.

STEREOSCOPIC CINEMATOGRAPHY.—No. 25,860. Stereoscopic motion pictures. L. Hammond.

Applications, October 2 to 7 :—

DAYLIGHT PHOTOGRAPHY.—No. 26,816. Daylight photography. E. P. M. Fortun.

DEVELOPERS.—No. 27,200. Photographic developers. E. C. R. Marks (Daylight Film Corporation).

LENSES.—No. 27,159. Photographic lenses. Kapella, Ltd., and H. W. Lee.

LENSES.—Nos. 26,553, 26,952, 27,052. Photographic lenses. Ernemann-Werke Akt.-Ges.

LENSES.—No. 27,188. Lenses. F. J. Russell.

RELIEF PHOTOGRAPHS.—No. 26,793. Production of relief or embossing effect on photographic prints, etc. E. Bardili and C. H. Kruger.

CINEMATOGRAPHY.—No. 26,795. Cinema photography and projection. J. Cooper and Stereo Kinema Syndicate, Ltd.

COLOUR CINEMATOGRAPHY.—No. 27,174. Colour cinematography. A. H. Bannister.

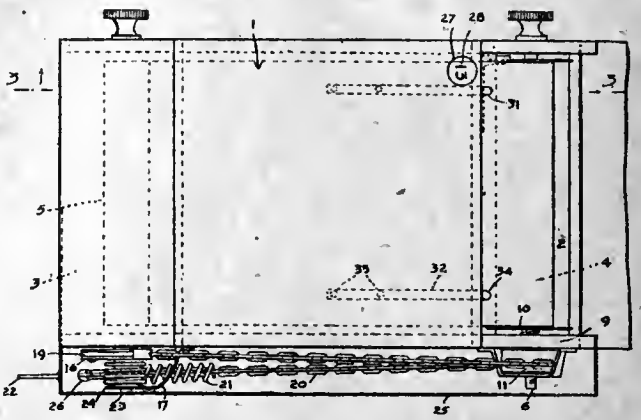
COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

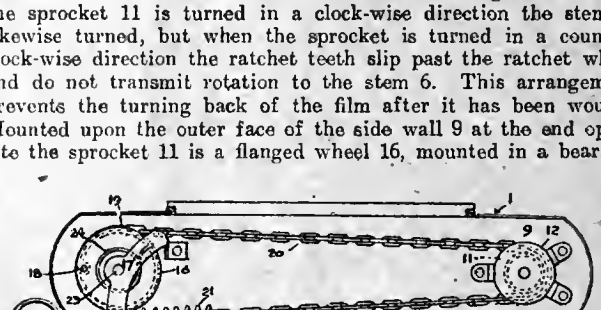
The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

ROLL-FILM CAMERA MECHANISM.—No. 165,756 (July 1, 1920). In the invention, the unwinding of the film to present a picture section in proper position for exposure is effected by pulling a chain, so that when the section is in proper position it is frictionally held. Further pulling of the chain can only be effected by overcoming the resistance whereby the operator is warned that the film is in the proper position.

The illustrations show a folding pocket-type of camera. At the ends are provided compartments 2 and 3 for a winding roll 4 and a film roll 5. These rolls are inserted in the usual way.



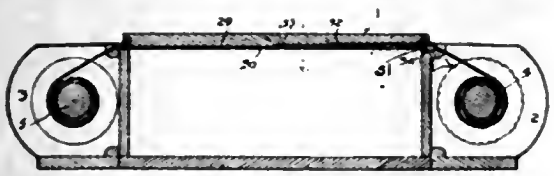
The film from the roll 5 is connected in the ordinary manner with the winding roll 4. In one end of the compartment 2 for the winding roll there is provided a winding stem 6 having a head 7, which is inserted into the transverse notch 8 in the end of the roll. This stem is rotatably mounted in the side wall 9 of the camera, and is longitudinally adjusted. It is normally extended by a helical expansion spring 10. The stem 6 is extended through the centre of a sprocket wheel 11, which is mounted in a bearing 12 fixed upon the outer face of the wall 9. Ratchet teeth and the ratchet wheel are so arranged that when the sprocket 11 is turned in a clock-wise direction the stem is likewise turned, but when the sprocket is turned in a counter-clock-wise direction the ratchet teeth slip past the ratchet wheel and do not transmit rotation to the stem 6. This arrangement prevents the turning back of the film after it has been wound. Mounted upon the outer face of the side wall 9 at the end opposite the sprocket 11 is a flanged wheel 16, mounted in a bearing.



Fixed by a removable pin or screw 18 to the wheel 16 is an elastic band 19, which is wrapped around the wheel and extended in the direction of the sprocket 11. Connected with the end of the band is a sprocket chain 20, which extends over the top of the wheel 16, and is wound round the sprocket wheel 11 and returned beneath the wheel 16. The sprocket chain 20 is extended through a helical spring guide 21, fixed to the bracket and bearing 17, and upon the free end of the chain a ring is fixed. The axle 23 for the wheel 16 has a helical spring 24 mounted thereon, and this is fixed to the bearing 17 and to the wheel 16 so as to return the wheel to its normal position after the chain has been pulled. In rotating the wheel 16, the elastic band is unwound. When it is desired to unwind a film roll so as to present a picture section of the film in position for exposure, the ring on the free end of the chain is grasped and the chain pulled to its full extent outwardly. This causes the sprocket wheel to be rotated in a clock-wise direction, and by reason of the ratchet arrangement between

the stem and sprocket wheel, the winding roll 4 is also rotated and the film wound thereon.

The length of the chain is such, and the mechanism so constructed that when the first film section is brought into position for exposure one pull only is required to move the next section into position. As a warning to the operator that the picture



section is in proper position, the projections 31 engage with the openings 31 and further movement of the chain is met with resistance.—Kotaro Sayo, 1820, Post Street, San Francisco, California.

PHOTO-STEREO SYNTHESIS.—No. 158,552 (January 21, 1920).—The invention, which was described in detail in the "B.J.," 1921, February 25, p. 110, consists in preparing a number of positive transparencies representing successive planes of the subject, and mounted one behind the other. The intervals between the transparencies are proportional to the separation of the planes in the original subject, and to the scale of reproduction. The transparencies are then mounted in such a way that they are illuminated by strong transmitted light, from a chosen standpoint, and when viewed produce the sensation of solidity. The camera used in connection with this invention is capable of being moved from or towards the object, along the principal axis of its objective for each exposure, so that the object is photographed in successive parallel planes. The extent of movement of the camera is equal to the distance separating the successive planes of the object. The objective and the sensitive plate are also displaced continuously during each exposure in the plane of the objective and the image plane respectively. These displacements are kept in constant ratio to each other.—Louis Lumière, 262, Cours Gambetta, Lyons, France.

SWING-FRONT LENS MOUNTS. No. 184,908 (May 30, 1921).—The invention consists of a spherically-jointed lens mount for enabling the optical axis of the lens to be swung in any direction within angular limits. A funnel-shaped ring takes the lens and shutter, and this is attached by means of a slightly wider ring to the camera front. The two rings are kept in contact, and are able to move, one over the other, in all directions. A lens with a shutter body is indicated diagrammatically at 10, fig. 1, carried by the wall 11, which closes in the front or large end of a hollow spherical shell 12. The outer surface of the shell 12 works against the inner surface of a stationary hollow spherical chamber 13 carried by the panel 14. The common centre of these two chambers is at 15, within the lens 10, at the rear principal

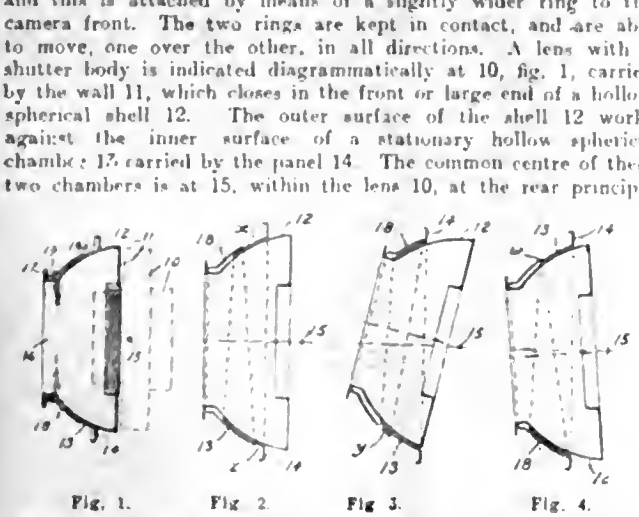


Fig. 1. Fig. 2. Fig. 3. Fig. 4.

point of the optical system, and outside the plane of the camera front. The moveable shell 12 is open at its smaller end, where it is formed into a cylindrical portion 16 carrying a ring 17. This is detachable, and the drawing shows it as screwed on. A ring 18 bears against the outer surface of the chamber 13, and is retained in contact by means of a spring 19 under compression between the rings 17 and 18. It will be seen that in this way the two shells 12 and 13 are frictionally held in moveable contact the one with the other, and that if 13 is held stationary on the lens panel or camera front the axis of the lens 10 can be swung in any direction within angular limits about the rear principal point 15 of the optical system. Figures 2, 3 and 4 represent various positions obtainable, the panel 14 being stationary and fixed to the camera front.—Claude Horace Clarke, Dorincourt, Maresbrook, Essex.

PHOTOGRAPHIC REPRODUCTION OF TYPE CHARACTERS.—No. 182,887 (April 7, 1921). The invention provides a rectangular frame in which is carried a number of characters arranged behind a source of light. Shutters are fitted in front of each character, and can be operated by hand or pneumatic power.

The images of the characters are projected by means of suitably placed lenses and prisms to a common focus on a movable sensitive band, which is conveniently placed in a suitable compartment, and mounted on reels. The shutters may be operated by hand from a keyboard, each key of which represents a character or space. By depressing a key the corresponding shutter is operated, and the band moved transversely, after each depression, in a similar manner to that employed on a typewriter. It is therefore possible to obtain a line of exposures, representing the characters, on the sensitive band.

A perforated strip may be used to operate the shutter mechanism if required. This strip passes over a tracker bar, in which are a number of apertures, so connected to the shutter mechanism that when a perforation passes over an aperture in the bar the exposure is made.—Walter Broadbent, 54, Rosebank Avenue, South Harrow, Middlesex.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

VELOPHOT.—No. 427,299. Photographic apparatus included in Class 8. "Velophot" Erzeugung und Vertrieb Photographischer Neuheiten Gesellschaft mit Beschrankter Haftung, 4, Concordiaplatz, Vienna I, Austria, manufacturers. June 22, 1922.

REGISTRATIONS RENEWED.

ORTHINAL. No. 307,395. Ilford, Ltd. Registered in 1908 in Class 1.

TRADE MARKS REMOVED FROM REGISTER.

In the official language of the "Trade Marks Journal" the following trade marks have been "removed from the register through non-payment of renewal fees." Such non-payment is of course the method adopted by a firm having no further occasion for the use of a mark.

BROMOIL.—No. 303,928. John J. Griffin & Sons, Ltd. Registered in 1908 in Class 39.

ESSYSOLIS.—No. 304,684. Houghtons, Ltd. Registered in 1908 in Class 1.

ESSYSA.—No. 304,685. Houghtons, Ltd. Registered in 1908 in Class 8.

ESSYSA.—No. 304,[illegible]. Houghtons, Ltd. Registered in 1908 in Class 39.

New Materials.

BUTCHER'S MOUNTING STAMPS.—As an easy method of mounting photographs, the adhesive mounting stamps, supplied by Messrs. W. Butcher & Sons, Ltd., Camera House, Farringdon Avenue, London, E.C.4, are a great advance, as regards cleanliness and convenience, upon the usual methods of mounting with paste. These stamps consist of pieces of fairly stout paper measuring only ¾ in. by ½ in., gummed on each side. To attach a photograph to a mount, four stamps are taken, and, after moistening, are stuck to the corners of the print. When these are dry the exposed side of each stamp is then moistened and the print placed in position on the mount. Each corner should be firmly pressed down, and a sheet of plate-glass placed on top of the print. Photographs may be mounted by this means on very thin paper or in albums. The mounting stamps are now issued in the form of a pad, with perforated sheets interleaved with grease-proof paper. The perforations allow the stamps to be easily detached, while the pad is a clean and convenient method of storage. The price per pad of 200 stamps is 1s.

New Books.

Practical Color Photography. By E. J. Wall. Boston: American Photographic Publishing Co.

PROBABLY among the various text-books dealing with photographic subjects one on colour photography is the most sought after, since it interests not only those who are practical workers of the Autochrome and Paget processes, but also those who take a general interest in the subject and have a taste for trying their hand at the many processes of making three-colour prints and transparencies by one or other of the assemblage methods. A comprehensive text-book of the subject on practical lines is, therefore, one which should be available. Such a book, however, which is close upon the heels of what has been accomplished in colour photography, has not, unfortunately, been available for some years. Mr. Wall has filled the breach in the excellent way which was only to be expected from his wide acquaintance with the subject from both the practical and historical standpoints. The latter aspect of the subject, however, receives little emphasis in the present work, which concerns itself predominantly with the technique of the various processes of colour photography, makes brief mention of their origins, and gives sufficient exposition of the principles of colour and colour mixtures for a ready understanding of the theory of the processes,

Many workers at the present time will purchase a book on this subject for its information on the screen-plate (Autochrome and Paget) processes, and the production of colour transparencies upon this principle thus appropriately forms the longest chapter in the book. The mechanism of colour reproduction by a mosaic filter-plate is very clearly shown by diagrams; and this part of the work contains full formulæ for compensating light-filters, developers, correcting screens for use in the viewing of transparencies by artificial light, in addition to sections on the copying of screen-plate transparencies, and on stereoscopic work with screen-plates. The chapter does not attempt to reproduce the working instructions issued for the use of the Autochrome and Paget plates, but usefully supplements these latter, and the only criticism which may be made in respect to it is that the author has not sufficiently emphasised the features of the Paget process, and has said practically nothing about its manipulation. A page or two might usefully be added on the making of the Paget positive transparency and its registration with the viewing screen.

The three-colour methods, additive and subtractive, are very comprehensively treated, and the student will obtain from the book a good working knowledge of current practice in the making of the set of three colour-sensation negatives and their use in the production of prints or transparencies by the assemblage method. The printing processes which are considered in detail are carbon, Pinatype, dye-toning, gum-bichromate, in addition to methods depending upon the production and staining of a gelatine relief. Mr. Wall has had a long first-hand experience in these methods and has made good use of his material in putting the essential details of the processes in compact form. Three-colour lantern-slides is the subject of a special chapter in which is described the making of transparencies with dyed relief on celluloid film; and in this place also instructions are given for the making of a photochromoscope for the viewing of three-colour effects on the additive system. The later chapters deal with methods which could not be omitted from a treatise on colour photography, although they are of much smaller practical interest. These are the bleach-out process, the Lippmann or interference process, the interesting optical methods by diffraction and prismatic dispersion, and also the methods which figured largely in the early days of photography, when much was expected of the colours which silver chloride assumes when exposed to light of different colours. The book is made complete and up-to-date by chapters on two-colour processes, including the Kodachrome, and on the systems of simplified colour work which have been embodied in materials such as the tri-pack of Mr. Ives. The final chapter is a brief review of processes of colour cinematography. In short, the book is a practical manual for the student and experimental worker, to whom it can be recommended as a complete and trustworthy source of information.

PRACTICAL COLOR PHOTOGRAPHY.—By arrangement with the American publishers, Messrs. Henry Greenwood & Co., Ltd., are able to supply copies of the new book, "Practical Color Photography," by Mr. E. J. Wall. The book is supplied post free to any part of the world at the price of 13s. 3d.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held on Tuesday, October 17, Dr. G. H. Rodman in the chair. Squadron-Leader F. C. V. Laws, O.B.E., R.A.F., delivered an interesting lecture, illustrated by many lantern slides, upon the subject of "Progress in Aerial Photography."

Major Laws, in referring to the state of aerial photography, said that in 1914 it was difficult to locate unmounted troops at 3,000 ft., while at the present time such advances had been made that pigeons feeding upon the ground could be easily seen in photographs taken from a height of one and a half miles. Since 1918 thousands of square miles of territory had been covered for the purposes of mapping, but Major Laws did not make the claim that the aerial photograph would take the place of the ground survey map. The aerial photograph would rather help to speed up and assist in mapping, while for surveying forest land and difficult tracts of country the photograph would be of great help. Major Laws referred to the Fairchild survey in the United States, and related how on the occasion of an aerial survey being made for a railway company a large cemetery was found to be directly in the line of the proposed construction. It was only possible to prove such cases from the air, the ground survey being much more difficult and less decisive. For the correction of maps, aerial survey was of great assistance, and the lecturer showed a series of lantern slides illustrating the method of constructing a map from an aerial photograph. A photograph of Mons was shown, first as it was rendered by the camera; the important details were then outlined in waterproof ink and the photographic image bleached out. The resulting slide gave a perfect map appearance. The important difference between this and the Ordnance Survey map was

that the photograph showed the exact position of all the railway lines and sidings, while the survey map did not. Insurance companies were using aerial surveying to show the accessibility of property insured. The photograph gave an excellent idea of this work, and the time occupied in the actual survey was negligible as compared with a ground survey. Some excellent mosaics were shown. These comprised many separate prints, which were overlapped and joined in such a manner that the resulting air picture resembled one large view, probably covering many square miles. Some aerial slides by the Central Aero-Photo Co. and Aero-Films, Ltd., were shown, an oblique picture of Bath being much admired. Oxford, with its white stone buildings, also made an imposing view, while the aerial view of the Cup Final last year, by Aero-Films, Ltd., was as perfect as this class of work can be. Major Laws also considered that the aero photograph was of great value for advertising purposes, but that part of the business should be left to private concerns. The Services at the present time were taking great interest in aerial photographic survey, and much important work was being done. Major Laws said that since 1919 his duties had taken him over the greater part of Europe and the East, and he had realised how important was the work of aerial survey.

Explaining the types of camera used prior to the Armistice, Major Laws said that the pre-armistice camera was a very bulky object. Using as it did, 5 ins. x 4 ins. glass plates in magazines and taking lenses of long focal-length, it was an awkward piece of apparatus. The lack of perfect balance in the plate changing system was very unfortunate. The total weight of the plate camera and all its accessories, when using 18 x 24 cm. plates, was 260 lbs., while the plates and magazine with the changing gear weighed 190 lbs. alone. The mechanism was not by any means perfect, and the alternative exposing gear was not in such a high state of efficiency as it is to-day. Referring to the chance of breakdown in the camera, the lecturer said that an aeroplane cost £10 an hour to fly, and if the camera could not take the photographs required owing to some fault, it was going to be a costly matter. The 150-exposure film camera which was now being used weighed only 45 lbs., while it occupied the same space as the plate camera. The ideal aerial camera, as described by Major Laws, was light in weight, small, simple, yet automatic in action. Its centre of gravity should be constant, and lenses of any focal length could be used. The film or plate should be held stationary during exposure and in the exact focal plane. Major Laws also recommended that an efficient between-lens shutter should be used. The new camera with which the Services were now working followed closely upon the lines of the ideal, and many important improvements had been made. This camera would make a negative 7 inches square upon film, and during exposure the particulars of the altitude of the plane, angle of tilt, date and time are recorded upon the margin of the film and show upon development of the image. This camera had three controls, one electrical, which could be set to work automatically with a regular interval between each exposure; another, which was situated in the pilot's or observer's cockpit, and which had for its mechanical power a small propeller working in the slip-stream; and a third, which was hand-operated, for use should the others fail. Lenses up to 47-ins. focus could be used. This camera was of great use for filling in map-work, or for survey over country where ground work was difficult or impossible. Major Laws showed some slides of a multiple lens camera, in which five lenses were mounted in close proximity to each other, the central lens being used upon its optical axis.

The other lenses had reflecting-mirrors fitted at an angle of 45 deg. to each, and a series of pictures taken in four directions, and also the central view, were recorded upon the one plate. This camera was only in the experimental stage, and had not yet been into the air. Speaking of films for aerial photography, Major Laws said that the film camera was now taking spools measuring 50 ft. by 8½ in., and there was great difficulty in developing and washing such a large mass of film. A new type of developing drum was shown, which had the advantage that it was possible to develop and wash the large films used without touching them in any way by hand; thus preventing finger markings, which were so difficult to remove. Referring to the mounting of the camera in the aeroplane, Major Laws said that the new triple frame was very efficient. The vibrations of the plane were easily overcome by this new attachment, especially the difficult adverse vibrations which effect the sharpness of the photograph most. Some interesting slides were shown which proved the efficiency of this new form of mounting, and a method of recording the adverse vibrations of the plane was also shown. This consisted of flying an aeroplane at night over three powerful lights placed on the ground, with the shutter of the camera kept open and a plate exposed. With the old-type camera mounting a series of saw-shaped bands of light were formed on the plate, while with the triple-frame mounting a nearly straight line was produced. Another interesting series of slides comprised sections of high-speed cinema films showing the bursting of flash bombs, while an actual photograph of the ground taken by the light of one of these bombs showed a hut illuminated brilliantly at 2,000 feet distance. A series of excellent mounted photographs had just been returned from the International Aerial Exhibition at Brussels, and were on view; and one of St. Paul's, taken at 8,000 feet with a 20-in. focus lens, actually showed the pigeons feeding on the steps of the building. In conclusion, Major Laws referred to the value of aerial photographs of such subjects as were not visible in the ordinary way. He illustrated his remarks by showing some excellent slides of the Pyramids, which clearly showed the outline on the ground of buildings which had apparently occupied the position in ancient days. These details were not visible from the ground.

At the request of Dr. Rodman, a very hearty vote of thanks was accorded to Major Laws for his lecture.

CROYDON CAMERA CLUB.

The gentleman whose privilege it is to write the weekly report of this Club (whether he is "office boy," "potman," or what, I do not know) has this week, with more modesty than real occasion, thrown up his task, because the notice necessarily takes the form of a critique upon the house exhibition which has been open this week to the public. Where this angel has feared to tread I have been rushed in at short notice, and, with considerable pleasure, have undertaken what I should have been sorry to miss.

The exhibition is distinctly good, and in one respect at least, is rather unique, if there can be degrees of uniqueness; for it possesses a print of a kind rarely seen, and still more rarely one so good of its kind. This is E. A. Salt's "Portrait by Candlelight" (1). I have seen it before, or one like it, and am glad of another view of it, because it exhibits purely and absolutely the beauty which simple illumination brings about through gradation. The rapid passage of light to dark upon the pillow is real drama in light and shade; the halo round the candle-flame is a marvel; and the whispers of creeping light in the uttermost depths of the dark parts are a joy because they satisfy reason and logic, yet have all the poetry of mystery. And then the charm of the sitter!

Another poem is H. P. C. Harpur's "Sunlight" (17), an architectural interior of great truth and beauty; especially as regards the church window. The quality of this is very fine. The big, dark, near pile should have been shorn right away (for the window is interest enough) and the print been sent to the Salon or Royal. Another by Mr. Harpur is "Slopes of Ide Hill" (85), a charming landscape, wherein perhaps the sheep are a trifle assertive. His "Peace" (81) a quiet sea and setting sun, is in perfect keeping.

Bromoil cannot be said to be the favourite method at Croydon: but nevertheless some of the best work is pigmented. E. J. Wadham's "Butter Market in a Church Porch" (19), is cleverly treated. The church is nice in quality and the peasant crowd pictorially interesting. "A Passing Storm" (30) is a mountainous scene by J. T. Morgan, produced with the pliability we attribute to Bromoil; but it is a bromide. When we come to J. Keane's "On Reigate Heath" (43), we see what delicacy and yet what firm surfaces Bromoil may be capable of. Here is lovely quality, with just tones in the trees and horse and cart; splendid effect of daylight and a delightful composition. S. J. Taylor's "St. Paul's from London Bridge" (49), is another Bromoil of quality; but the barges in the foreground are sad anti-climax. The bottom half of this print wants eliminating. Mr. Taylor's other Bromoils are all charming, particularly "Sunshine" (61) and "Thaw" (62), a fine essay in strong work. What is shown of "Cologne Cathedral" (72) in J. Walker's bromide is first rate. The print is a decorative strip; but it has a sense of space in spite of its drastic trimming. His view of a foggy effect on what appears to be the Thames Embankment shows a real sun in the sky, and makes a beautiful picture, of the photographic kind, called "November" (79). Another successful sun in a mist is seen in "The Pool" (73), by H. C. Inskeep, whose "Pine Woods" (77) is fine also, but in a different direction. It is beautifully composed, and has very convincing tone values.

A chloro-bromide print of "Castle Mill, Dorking" (74), by N. Moody, possesses an unphotographic quality of tone that may or may not be due to the process. The sun on the white walls is luscious, and the whole thing is charming. I don't quite know what I mean by unphotographic quality; certainly I could not explain it; but in pointing out A. E. Isaac's "Stare Cove, Lulworth" (40), I should say that its quality was what we mean by photographic. This, of course, has nothing to do with the selection of subject or general design, which is admirable.

N. Moody's "St. Paul's from Bankside" (51), has the great merit of being an original view. It includes part of an immense arch, beyond which is the cathedral, opposed in sentiment, as well as in tone, by a great crane that stands before it. This is a most successful work in every respect; full of artistic feeling. Another excellent and original selection is J. M. Sellor's "Man's Handiwork" (80)—the stone-work around the western end of the St. James's Park lake. Mr. Sellors has seen and secured the palatial renaissance feeling of all this, and made a dignified subject. His other works show his sensitiveness to the beauty of line and contrast; and V. Jobling's collection of portraits of the young show where his tender spot is.

The muster is 87 examples, all interesting, including a collection of the coloured portraits produced by E. G. Handel-Lucas's process, which baffles everybody but himself. They are astounding results; none the worse for keeping close to the photographic image when it is worth keeping close to; but Mr. Lucas will have to be careful of his shadows where the photographic basis is disposed to be incorrigible.

S. W. Rose and N. Moody supply a little Paget Colour show, most ingeniously and effectually displayed.

No one would believe, from the hilarious reports which have made this club famous, that there was seriousness of purpose enough to produce a show of such high merit.

F. C. Tilney.

Forest Hill and Sydenham Photographic Society.—On October 11, Mr. Cutbush, a member, gave an interesting lecture on tanks and tank development, and showed various kinds of tanks, including one of his own design, which has all the advantages and none of the drawbacks of the previously existing ones. It is of the horizontal pattern, and can be used for one plate only if desired, or for any number up to twelve, only using the quantity of developer required for the plates to be developed, thus effecting great economy in use. Moreover, it is constructed so that it is impossible to put two plates in the same groove, a boon to users of panchromatic plates.

Glasgow and West of Scotland Society of Professional Photographers.—At the meeting held in the Regent Studio (Messrs. Brinkley & Son), Glasgow, on October 9, interesting and instructive demonstrations on spot lighting, Eastman film and diffusion discs were given by Messrs. Laurence, Webb and Scott, of Kodak, Ltd. The lecture and demonstrations were greatly appreciated by a large audience. During the evening the lecturers exposed and developed films, which were exhibited to the audience. Mr. J. R. Brinkley, the President of the Society, occupied the chair. Votes of thanks to the lecturers terminated the meeting.

Commercial & Legal Intelligence.

NEW COMPANIES.

Burroughs, Wellcome & Co. (South Africa), Ltd.—This private company was registered on October 5 with a capital of £20,000 in £1 shares. Objects: To acquire the business carried on by H. S. Wellcome at Cape Town as "Burroughs Wellcome & Co.," and to carry on the business of dealers, wholesale and retail chemists and druggists and druggists' sundriesmen, photographic dealers, etc. The first directors are: H. S. Wellcome, 6, Gloucester Gate, N.W.1; G. E. Pearson, Embassy Hotel, Bayswater Hill, W.; J. C. Smith, Holmwood, Cumberland Park, Acton, W.3 Qualification: One share. Remuneration: As fixed by the company. Secretary: G. L. Moore. Registered office: 67, Holborn Viaduct, E.C.

News and Notes.

The Service Co., Ltd. (London), inform us that they are removing the photographic section of their business, at the end of the present month, to new premises, at 273-274, High Holborn, London, W.C.1. The new premises are situated only a few doors west of the old address.

Barkay Reflectors.—These reflectors for the portrait studio, the advantages of which were the subject of an article in our pages some weeks ago, are now supplied by the actual manufacturers, Messrs. Robinson, King & Co., Grove Glass Works, Marshgate Lane, Stratford, London, E.15.

Heliolette Background Negatives.—The series of these film negatives, which formerly were supplied by Mr. J. A. T. Fraser, have now been taken over by Messrs. Jefferies & Co., Ltd., Pembroke House, High Road, Seven Kings, Essex, who supply them in a considerable variety of size and subject.

"Camera House Journal."—The October issue of Messrs. Butcher's publication contains particulars of goods for the winter trade. The "Dualito" electric enlarging lantern, in both horizontal and vertical models, and the "Club" optical lantern are striking items. Home cinematography is catered for in the various models of the "Empire" projector. A clearance of albums is also announced.

Aldis-Ensign Vertical Enlarger.—A distinctive folder, which explains the working of this new type of vertical enlarging lantern (recently noticed in our pages), has just been issued by Messrs. Houghtons, Ltd., 88-89, High Holborn, London, W.C.1. The folder demonstrates, in a striking manner, the advantages claimed for the enlarger; dealers are advised to obtain copies for distribution to their customers.

Photographic Societies Amalgamate.—The South Suburban Photographic Society and the Catford Camera Club have amalgamated. The fusion has been brought about not because of any sign of weakness—each having about seventy members and money in hand—but by a desire to form a particularly strong society in the S.E. district of London. For some years past the two societies have been meeting weekly on the same evening and within a short distance of one another. The combination is to be known as the South Suburban and Catford Photographic Society, and the meetings are held every Wednesday at the Plough Hall, Lewisham Obelisk, S.E., where the South Suburban has met for the past fifteen years. The vice-presidents, committees, and hon. secs. will act together, with Mr. P. R. Salmon as president and Mr. H. H. Featherstone as vice-president, until the annual meeting in April next. The joint secretaries are Mr. H. D. Fretwell, 10, The Grove, Greenwich, S.E.10, and Mr. Frank Coleman, 24, Ennersdale Road, Hither Green, S.E.13.

Big-game Photography.—The most-talked-about photographs in the National History Section at the Royal Photographic Society's Exhibition are three East African big-game subjects taken by Mr. M. Maxwell, who, the daily papers state, is out in Africa again with camera, motor-car, and gun. Naturalist photographers will be interested to learn that some of Mr. Maxwell's wonderful work has just been put on public exhibition in the Natural History Section of the British Museum at South Kensington. This is an exceptionally fine series of photographs—measuring about 4½ ft. by 2½ ft., and it is to be found round about the Darwin statue, in the main hall.

One photograph, showing an elephant in dense thorn bush, illustrates how difficult it is to detect the animal amid such tropical surroundings, while another shows an elephant standing conspicuously in the open. To get this Mr. Maxwell, we are told, had to reach the scene at dawn, before the herd took to the bush. In one instance an elephant has been photographed just at the moment when he detected the presence of the photographer, while another scene shows the huge creature getting restless, and in the act of swaying one of his legs in a characteristic attitude of indecision and suspicion.

IRIS AND WATERHOUSE DIAPHRAGMS.

To the Editors.

Gentlemen,—In the condensed report of Dr. Clay's lecture it is stated that the iris diaphragm was first fitted to photographic lenses in 1882. This is not quite correct, as in the English version of Monckhoven's "Photographic Optics," published in London in 1867, on page 134 there is a diagram of Petzval's orthoscopic lens, which shows in both section and elevation an iris diaphragm of six leaves having a range in the size described of from *f*/8 to *f*/30.

With regard to the Waterhouse diaphragm, I believe that the gentleman whose name it bears only claimed the improvement of the projecting tang and the slotted rack jacket. The original form of Lake Price necessitated racking the diaphragm slot out beyond the jacket when it was necessary to change the diaphragms. I still have a pair of portrait lenses fitted with these early diaphragms.—Yours faithfully,

EDGAR CLIFTON.

JOHN WATERHOUSE, OF HALIFAX.

To the Editors.

Gentlemen,—You ask in an "Ex Cathedra" paragraph (page 613) for some particulars of John Waterhouse, the inventor of the "Waterhouse" stop. Twenty-five years ago, when at Halifax, I interviewed several of the then old hands who knew most of the Yorkshire worthies, and I was told that in 1855 Waterhouse investigated the problem of toning prints and introduced a "non-acid solution of gold chloride." The alkali he used was potass carbonate and he used "more or less of it according to the tone desired." According to Mr. Jerome Harrison, the process Waterhouse invented was that published (in 1856), in the third edition of Hardwich's "Photographic Chemistry," and subsequently recommended in a paper read by Mr. Hardwich before the London Photographic Society (see "Photographic Journal," Vol. 5, p. 95).

One Halifax septuagenarian was of opinion that John Waterhouse—of whom he had heard but never knew—left his native town for London, but I cannot believe he did so. Had he come to London more would have been heard of him.

In your paragraph you refer to the "small projecting piece" on the stop "which in later years was marked with the F No." I have looked through old handbooks and catalogues, and the earliest picture of a Waterhouse stop with F. No. lab that I can find appears in the 1863 edition ("Preface" is dated April, 1863) of Monckhoven's "Popular Treatise on Photography," translated by W. H. Thornthwaite. The chapter on lenses and stops deals with the older type of "ring," or loose diaphragm, and makes no mention of the "Waterhouse" pattern, but on page 45 there is a footnote which illustrates and describes "a new form of pierced lens mount for use with a series of diaphragms," namely, the "Waterhouse" pattern with projecting piece.

Maybe the whole story of John Waterhouse is buried away in the pages of some badly indexed book.—Yours faithfully,

A. S. JENNINGS.

PSYCHOLOGY IN THE WORKROOM.

To the Editors.

Gentlemen,—Mr. J. Effel dealt recently and in an interesting manner with the psychological aspect of studio work, but something might be said about the psychologist in the darkroom and printing-room. In these places accidents and mistakes will not grow fewer until we realise the fact that there are in the photographic world assistants who are born to trouble, and who sooner or later make the most terrible mistakes and have the most devastating of smashes.

Some assistants are foredoomed to accidents, and the problem is to find the "bad-luck" workers before too much damage is done. Most of us buy our experience in a very dear market, and it is hardly possible—at present, at any rate—to formulate tests by which applicants can be classed as good, average, and dangerous. Something of this kind was done a short while ago when a firm of caterers engaged a psychologist to weed out the "accident waitresses" from their many branches.

Accidents will happen in the best-regulated studios and workrooms, but many such accidents are due to carelessness. An assistant may go for years without breaking or scratching a negative, smashing a dish or measure, over- or under-printing, exposing on an empty dark slide, etc., while another worker may make a daily habit of doing these things. In a Paris studio in which I was once engaged there were twenty-six hands employed in the dark-rooms and printing-rooms, and changes were frequent. Each applicant for a post was, as far as possible, given a trial and carefully watched. He was made to handle negatives very quickly and purposely flustered, the principals being strong advocates of what may be called the science of industrial psychology. The idea was perhaps a little severe to an unsuspecting would-be assistant, but with large negatives—about 20 x 16 in.—of Louvre and other paintings the principals had to be careful in selecting their men.

J. V. S.

PURITY OF HYPO.

To the Editors.

Gentlemen,—On page 611 of your issue of October 6 you record an announcement made by Mr. W. G. U. Woolcock on behalf of the Association of British Chemical Manufacturers. This announcement may give your readers the impression that the "pea crystal" quality of hypo is generally inferior in purity, and an injustice would thereby be done to those British manufacturers who have been sufficiently enterprising to instal modern crystallising plants capable of producing this quality.

Whilst it is not possible to draw any conclusions regarding purity from the appearance of a crystallised product, and whilst it may be true that isolated samples of pea crystal hypo may be found upon the market which have a lower purity than the small crystal kind, as a general rule it may be stated that the uniformity of crystal size and shape in pea crystal hypo is strong evidence of careful manufacture, and more often than not the pea crystal quality will be found to be of the highest purity.

Personally, I always use pea crystal hypo or cube crystal hypo, because of its uniform quality and the readiness with which it can be handled. It runs "freely, and is usually dry. It is easy to weigh off and dissolve, and is never dusty.

The quality of hypo I am at present using, i.e., "pea crystal" of British manufacture, is certainly of a very high degree of purity and is, moreover, perfectly free from insoluble impurities.—Yours faithfully,

HUGH GRIFFITHS, B.Sc.

15, New Bridge Street, London, E.C.4.

THE 1923 P.P.A. CONGRESS.

To the Editors.

Gentlemen,—I am sure that no one doubts the great consideration that the Committee of the P.P.A. would give to any suggestion we sent direct to them, but if Mr. Speight had sent them his letter, instead of to you, it would have been only *one* complaint. By your publishing it, it has induced several other members to join him, each possibly having previously thought that he was the only one inconvenienced. A ballot of members would find out how many do favour the Spring Congress.—Yours faithfully,

T. EVERITT INNES.

The Studio, St. Petersgate, Stockport.

To the Editors.

Gentlemen,—Permit me to thank your four correspondents for their excellent letters in your last issue, protesting against another

Autumn congress. The letter from Mr. Alfred Ellis conveys the impression that he considers the subject is not a suitable one for your columns, but I maintain it is. Such an important matter is not to be settled by a few members writing to the Council. The question is of interest and concern to the whole body of the P.P.A., and even to the profession generally; for are not all professional photographers eligible for membership, and is not the Congress our most attractive asset?

For these reasons the controversy should have the publicity that is derived from the wide circulation of your journal.

There is nothing to be secretive about, for the point at issue is a plain one without complications. Here it is in a sentence: Would another September Congress meet with the approval of a majority of the members of the P.P.A.?—Yours faithfully,

JAMES SPEIGHT.

The Studio, Sutton Coldfield, Birmingham,
October 16.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

G. A.—We advise you to write to Messrs. G. and E. Russell, 202, Northfield Road, King's Norton, Birmingham.

H. E.—The best man for making your carbon colour prints is Mr. Samuel Manners, c/o Messrs. Raydex, Ltd., 71, Lavender Hill, London, S.W.11.

H. H.—We should think your best course would be to take up classes at the Regent Street Polytechnic, London, W.1, where you would be able to get instruction in all branches of the work, both in the studio and dark room.

J. R.—In all probability copyright has expired, but it is rather a complicated question since the engraving may be either an original one, or one made from a painting. If there is still copyright in the painting, it will be an infringement to make a copy of the engraving.

G. A.—To blacken your iron stops, clean off all the old black with fine glass paper and polish with tripoli. Then make the following solutions: Dissolve 40 grs. silver nitrate in 100 minims of distilled water; also dissolve 40 grs. of copper nitrate in 100 minims of distilled water, and mix the two solutions. Dip the stops in this mixture and let them dry. When dry they should be heated on a sand bath until they assume a fine black colour.

J. L.—The formula for a clearing bath for negatives, but using citric acid, is as follows:—

Alum	1 oz.
Citric acid	1 oz.
Ferrous sulphate	3 ozs.
Water	20 ozs.

The negatives should be immersed for about 20 minutes. If you wish to use sulphuric acid, replace the citric acid above by half an ounce of dilute sulphuric acid.

A PRESS PRINTER.—Your trouble is that sulphur is being deposited after a certain amount of hypo. has been used up in fixing the prints. We advise you to discard the formula you are using and make up the following:—

A.—Hypo.	4 lbs.
Potass metabisulphite	2 ozs.
Water	160 ozs.
B.—Chrome alum	8 ozs.
Water	160 ozs.

Mix the two solutions.

J. C.—About the best book for you is the "Writers' Year Book," published by Messrs. A. and C. Black, 4-6, Soho Square, London, W.1., price 3s. 6d., which gives the names and addresses of practically all the periodical publications which use contributed articles, and also photographic and other illustrations, together with their preferences in these respects. Another very useful book is "Willing's Press Guide," published by Messrs. James Willing, Ltd., King Street, Covent Garden, London, W.C.2, price 2s. Our publishers do not supply these books, but you can obtain either of them direct, if still in print, or through any bookseller.

F. F.—A formula for a combined developer-fixer for ferrotype plates is as follows:—

Hydroquinone	½ oz.
Soda sulphite	4 ozs.
Soda carbonate	4 ozs.
Hypo	8 ozs.
Liq. ammonia .880	2 fl. ozs.
Water, to make	40 ozs. fluid.

Addition of more ammonia to the developer gives more vigour. The plates develop (and partly fix) in two or three minutes. They can then be examined in daylight and fixed in plain hypo.

J. S.—Your dishes may be waterproofed by painting with the following mixture:—

Resin	3 lbs.
Plaster of Paris	8 ozs.
Red ochre	8 ozs.
Linseed oil	8 ozs.

Melt the resin over a gas ring, taking care it does not catch fire, and then add the other ingredients in the order named. The mixture should be applied hot, and the wood should be dry and warm. Brush the mixture well into the wood, especially at the joints. Reference to this process may be found in the "B. J." of August 20, 1920, p. 515.

H. K.—(1) The chief reason is that these direct positive cards are very much more thinly coated than ordinary plates or papers, so that a very short washing removes the excess of hypo. Also many of the emulsions for these cards are prepared with collodion instead of gelatine. We think it is plain that the particular samples you send are made with a collodion emulsion. Again, the hypo is much more rapidly removed from a collodion film than from one of gelatine. (2) No, it is a totally different process. The negative is developed in the ordinary way and then, without fixing, dissolved out and the remainder of the silver emulsion then treated in a developer which produces a positive. (3) The Photostat machines are supplied by the Kodak Company, Kingsway, London, W.C.2, who also supply the papers used with them.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3260. Vol. LXIX. FRIDAY, OCTOBER 27, 1922. Price Fourpence.

Contents.

SUMMARY.

Mr. J. Effel, in a further chapter on studio portraiture talks of accessories and backgrounds, and has some useful advice to give in a lively vein on the abandonment of the atrocities which may still be found in some studios, in the shape of both accessories and backgrounds. (P. 647.)

In a contributed article "Thermit" narrates some of his experience showing the directions in which the province of the professional and commercial photographer is invaded by amateurs, often possessing more confidence than experience. (P. 649.)

A very educated demonstration of art principles in the furnishing of the reception room was given before the last Convention of the Professional Photographers' Association of America, when the demonstrator, Mr. Ross Crane, of the Art Institute of Chicago, showed the great effect producible by study of design and colour in furniture and wall coverings. (P. 650.)

In a leading article further consideration is given to the general principles which, in common law, govern the relationship of master and servant. The present article deals especially with the circumstances of terminating an engagement and with the duties which a master and servant owe to each other during the period of employment. (P. 646.)

The chief precautions in the use of flashlight for groups are the subject of a paragraph on page 645.

Some hints on photographing exhibition fowls are given by a contributor to "American Photography." (P. 653.)

The text has now been published of the decision of the Referee under the Safeguarding of Industries Act respecting the classing of gallic acid as a fine chemical. By the decision gallic acid is restored to the list of fine chemicals protected by the Act, after having been removed from its original place therein by the Board of Trade. (P. 654.)

Bromoil prints may be inked up with a roller according to the technique described on page 646, although the dirtiness of the manipulation will discourage most people from adopting this method.

A recent patent describes an elaborate machine on the lines of the Linotype type-composing machine, but designed for producing negatives, on plate or film, of lines of type matter, which can then be printed for reproduction by lithographic, offset, or other process. (P. 655.)

A contributor to "Assistants' Notes" attributes the surface markings in the form of minute specks, sometimes produced on glazed prints, to the use of excessive hardening of the emulsion, or to too much pressure in squeegeeing. (P. 654.)

While a hot water radiator is an ideal means of warming the dark-room, the very necessary temperature of about 60 deg. F. may be secured with an ordinary blue flame oil stove. (P. 646.)

A correspondent raises the question of the preferable use of a yellow safelight, instead of red, for the handling of bromide paper, on account of the red-sensitiveness sometimes encountered in bromide paper. (P. 659.)

EX CATHEDRA.

The Election. Printers and photographers are, perhaps, the only two large classes of people who stand to benefit directly from the general parliamentary election, which will take place on November 15. In a series of contests throughout the country, which in all probability will turn out to be unique in the experience of the present generation, owing to the greater number of parties appealing to the electorate, the claims of candidates are certain to be very actively canvassed, and photography will probably play a larger part within the two weeks which have now to pass, than it has done in previous elections. It may reasonably be supposed that the very considerable proportion of women in the electorate of the country will prompt election agents to bring the personal characteristics of candidates before the voters, as can be readily done by the circulation of postcard portraits. The time is short, but it will not surprise us to hear that photographers able to supply numbers of postcard portraits promptly, or to obtain them from one or other of the firms which make a specialty of rapid print production, will be able to obtain plenty of business between now and the date of polling. The poster portrait is another form of election propaganda in which the photographer is concerned, and in the production of which he can draw upon the assistance of at least one firm, Messrs. Hood, of Middlesbrough, who for many years have included this work among their branches of photo-engraving.

* * *

Flashlight Groups. Unless the studio be provided with a somewhat extensive half-watt installation it is not easy to take large groups in the evening or on dull days, since the lighting, which is adequate for one or two figures, does not give a sufficiently diffused and powerful light. In such circumstances flash light can be made to do all that is needed, and, if properly managed, the results should be equal to daylight exposures. The principal points to be observed are to fire the flash at a sufficient height, say, eight feet from the floor, to keep the sitters from looking up at the source of light, and to have the studio as brightly lighted as possible while focussing so that the pupils of the sitters' eyes are not unduly dilated. Careful experiment must be made to ascertain the minimum of powder which will give the necessary exposure, many groups being spoiled by overlighting. A dilute developer should be used and the negative kept rather on the thin side. It must not be forgotten that the quantity of powder used varies with the diaphragm aperture. Thus twice the powder necessary for *f* 16 must be used if the aperture is reduced to *f* 22. For this reason it is desirable to use an anastigmat and to take full advantage of the swing back to obtain the necessary depth.

Warming the Dark Room. Even if we allow that the comfort of the operator is a matter of no consequence, the maintenance of a reasonable temperature in the dark room is essential to the production of uniformly good negatives. The old-fashioned practice of taking a jug of hot water with which to dilute the developer is a haphazard way at the best. It is far better to raise the temperature of the room to, say, 60 degs. Fahr., so that solutions which have been kept therein will be nearly at average summer temperature. If the building be provided with hot water pipes it is worth while running a branch into the dark room, but, failing this, a very good substitute will be found in an ordinary blue-flame oil stove, which should be placed under a bench by the sink, so that no light can reach the plates. It is advisable to remove part of the wooden top of the bench and to replace it by a slab of the asbestos sheet now so commonly used for partitions and roofing. This is incombustible, and will not warp. And it is not a good heat conductor, so that there is no danger of burning the hands, as would be the case with metal.

* * *

Roller Inking Bromoil Prints. The usual method of inking Bromoil prints, by means of a brush, becomes a tedious business when several prints have to be prepared quickly. Some degree of skill is also needed to obtain a good even deposit of ink on the print, more especially with subjects consisting of a large amount of shadow. These difficulties may be overcome, however, by inking the print with a roller, although the operation is such a terribly dirty job, that there are probably few enthusiasts, even for Bromoil, who will care to undertake it more than once. The whole of the surface is covered with a thin layer of ink, and after allowing the print to become partially dry, it is placed in hot water, and its surface gently rubbed with a wad of cotton wool or a brush. The ink now leaves the print in proportion to the image and a straight copy of the original bromide is obtained. This process differs very slightly from the ordinary Bromoil technique, bleaching, etc., taking place in the usual manner. The bromide print should, however, be upon a paper which consists of a fairly stout base; one which will stand the Bromoil transfer process will be found satisfactory. The print having been bleached, fixed and washed, is blotted off between fluffless blotting paper, and laid, film upwards, upon a sheet of glass.

* * *

The Ink. For inking any good quality lithographic ink may be used, but it has to be thinned down, before it is applied to the print. The best thinning medium is rectified turpentine, not the usual painters' variety, but the purified product sold by druggists. The ink should be rubbed down on a stone or glass slab by aid of a palette knife, and sufficient rectified turpentine added to produce an ink of the consistency of thick treacle. The roller used, is the ordinary proofing roller of the printer, and it should be charged by rolling over the ink on the slab several times, until a good coating is obtained. This is then applied to the print and rolling continued from end to end, until the print is evenly coated all over. Practically no sign of image will be seen, the surface of the print being completely covered with the ink. The print is now hung up for a while to allow the turpentine to evaporate. It is somewhat difficult at first to judge exactly when this has occurred, but it may be taken as a guide, that when the paper of the print is barely dry, the ink is in such a condition that further work may be attempted. The print is now placed, face upwards, in water, at a temperature of about 100 degs. F. After soaking for three minutes, the surface of the print may be wiped with a piece of cotton wool or lint, taking care to keep the print under water all the while. The ink will now be found to come away on the wool from the high-lights first, and then proportionately from the half-tones and shadows, and wiping should be continued until the full image has been "developed." As the wool becomes charged with ink it may be discarded and a new piece used. A flat camel hair brush is useful for removing the ink, as it has the advantage of giving a cleaner result, but it soon gets charged with ink, and is rather difficult to keep clean. Several brushes, therefore, would be needed to complete a print of moderate size.

SOME NOTES ON THE LAW OF MASTER AND SERVANT.—II.

In a previous article* the writer endeavoured to convey the point of view of a lawyer in considering questions affecting employer and employed, particularly as regards the establishment of this relation between two people and its termination. In the present article the latter aspect of employment is the subject of some further examination and the conditions of service in their relation to common law are also considered.

A servant may be summarily dismissed without notice for (1) wilful disobedience to a lawful and reasonable order; (2) misconduct inconsistent with the due discharge of his duties; (3) conduct outside the servant's employment rendering it unsafe for the master to retain him in his service; (4) immorality involving forfeiture of trust in the servant; (5) insubordination incompatible with the continuance of the relation; (6) habitual negligence; and (7) incompetency in performance of any skilled employment for which the servant was engaged, and the master may similarly terminate the employment if the servant becomes, through illness or accident, permanently incapable of performing his duties, though mere temporary incapacity will not give this right nor entitle the master to withhold wages. It is well settled that the master need not tell the servant on what ground the dismissal is based and that even if, at the time of dismissal, he knows of no good ground for the dismissal, he may justify his action if, subsequently, he discovers some act or omission on the part of the servant which would have formed a sufficient ground for terminating the employment summarily, if, at the time, he had been aware of it.

The servant may quit his employment without notice (1) if he has reasonable ground for apprehending that continuance in it will expose him to danger of loss of life or personal injury; (2) if he is subjected to severe ill-treatment by the master, and (3) if the master fails to carry out his part of the contract, as, for example, by refusing to pay the agreed wages. It is to be noticed that failure on the part of the master to perform his part of the contract puts an end to the entire contract, so that the servant is not only freed from any obligation to continue in the employment, but also from any collateral term of it, such as a restriction on his right to carry on business in competition with his late employer.

A servant who gives his master cause to dismiss him summarily or who leaves his employment without proper notice or justification may find himself in an unpleasant position from a financial point of view, for not only will he lose the wages which he would otherwise have earned, but he will also forfeit the wages for the period which

* "B.J.," 1922, October 13, pp. 614-615.

has elapsed between his last pay day and the date of leaving his employment, although he will, of course, be entitled to any wages which may actually have become due to him before the termination of the contract and remain unpaid. Moreover, it must be remembered that in no case is a master under any obligation to give a servant a character, though if he gives one he must be careful that it is accurate.

Having seen how the relationship can be created and terminated, it may be useful to consider the duties which master and servant owe to one another during its continuance and on its termination. In the first place, although in his own interests he is likely to do so, the master is, generally speaking, under no obligation to provide work for the servant to do, except where (as in the case of a servant paid by commission) the remuneration depends upon the amount of work done, so that, so long as he receives his wages or salary, the employee cannot complain if he is kept in a state of enforced idleness. On the other hand, apart from such recent legislation as the Shop Hours Act (which, however, only applies to persons employed in shops as defined by the Act) the law does not recognise any right in the servant to require a holiday, though, of course, a holiday or holidays may be stipulated for at the time of entering into the contract, or may, by reason of the general custom of the class of business in which the servant is employed, be deemed to be an implied term of the contract. For instance, the weekly half holiday is now so generally recognised in all classes of business that it is practically certain that the Courts would uphold the servant's right to it, unless such right were expressly excluded by the terms of employment. The law will not permit the servant to be put to expense in carrying out his duties, and consequently the master must indemnify him against all expenses and liabilities incurred in obedience to orders or in the reasonable performance of his duties. This, of course, does not mean that a servant can require reimbursement of extravagant payments made by him in the course of his employment. For instance, a servant who is sent from London to Brighton to take a series of photographs would not be justified (in the absence of very exceptional circumstances) in hiring a car for the journey or staying at a luxurious hotel when other reasonable accommodation was available, and the master, in such a case, would be within his rights in refusing to allow him more than the third class return fare and reasonable hotel expenses. If the servant, pursuant to orders, carries out some transaction which he knows to be unlawful he must take the full consequence of his acts and cannot look to his master to indemnify him against any liabilities which he thereby incurs towards third parties.

A servant must obey his master's lawful commands, take proper care of his master's property committed to his charge and use reasonable care and skill in the execution of his duties, and failure to do so may not only justify his summary dismissal, but may also expose him to liability for damages at the suit of the master.

Unless expressly restrained by the terms of the contract of service, a servant is at full liberty, after his employment has come to an end, to set up in business in competition with his late employer and, in such business, to use the knowledge he may have acquired in the course of his employment. He may even ingratiate himself with his master's customers during his employment with a view to securing their custom after the employment ends, but he must not during his employment surreptitiously make lists of his employer's customers and then canvass them for orders when he sets up business on his own account, and if he attempts to do so the Courts will restrain him on the ground that he is guilty of a breach of faith.

It has already been stated that, by the contract of service, restrictions may be placed upon the servant's right to set up business in competition with his employer after the employment ends, but such restrictions are very jealously regarded by the Courts and the servant will be released from them if they go beyond what is reasonably necessary for the protection of the master's business.

G. E. S.

WITH A PORTRAITIST IN THE STUDIO.

[In the present paper, of the series of articles by Mr J. Ettel, which has been appearing in recent issues, the author talks of accessories and backgrounds, and, from instances in a wide experience, urges the abandonment of the many artificial accessories still to be seen in portrait studios. The next article of the series will deal with hands and feet and full-length portraits.]

IX.—ACCESSORIES AND BACKGROUNDS.

In at least one particular the photographer is worse than the criminal, for the law breaker may be guilty of using an accessory *after* the fact, but the studio worker has seldom such refinement of artistry, the accessory invariably preceding the sitter in composition.

We have to think of things and words in their real significations if we are to get out of conservative error and stagnation; slip-shod definitions, and meanings accepted because they have been current for so long that the timid are afraid of change, count for nothing to the man with a mission. All around us are evidences of change great dynamic forces are at work everywhere; only the studio is static. Ask Snapshotte what an accessory is, and he will tell you it is a garden seat or a French window, or some other contraption in "paper mashy," and maybe he will add that you are a fathead not to have known that long ago. Now, even at the risk of incurring Snappy's impatience with my ignorance, I will be humbly bold, and affirm that an accessory may be more than plaster of Paris, and a background something different from a painted screen that is like nothing on earth.

I would define the word "accessory," used in the studio sense, as anything, other than the wearing apparel, that assists or contributes in any particular to the picture. The photographer's first duty is the production of a likeness—indeed, in many parts of the country he is still spoken of as the "likeness taker" and the face and clothed figure of the client should be considered before the Grecian pillar or the Handel stool. In most things I have the courage of my passion, and if I placed great reliance on the use of accessories in my portrait work I would give my pictures suitable titles, "Study of an oak settle, with lady," "Perambulator and child," "Rembrandt effect of bookcase, with 'B.J.' Almanac disclosed, also clergyman reading same," would strike you as being frightfully silly, but they would nevertheless be eminently descriptive of the class of work I have in mind. Yes, we may deplore the criminal's unsocial acts, but we must count it unto

him for righteousness that in the use of accessories he can prove an object lesson for most portrait photographers.

We only fully realise the enormity of the accessory offence when to its hideous incongruity is added what is spoken of as "the background." There was an old photographer in my youthful days who had a great love for a curtain. He dressed it up in many different ways and got some variety out of it, but his operator and he used to have heated arguments. The young man would try all he could to get rid of the velvet drapery, but with little success, for just as he was about to expose the boss would creep into the studio, and whisper loudly, "Introduce the curtain, introduce the curtain." Indoor or outdoor subject, it mattered not, the old man was obsessed by his one great adjunct to a successful portrait. It was in vain that the operator told him that introductions were superfluous between acquaintances of long standing. Sarcasm was wasted on the old die-hard whose last words most likely were "Introduce the curtain."

After all, a curtain is not an unlikely background; it is certainly mobile, and can be wheedled into quite a number of effects. But when we think of the painted canvases on rollers or stretchers, representing every phase of nature from a snow scene in Switzerland to moonlight in the Lake district, and every style of apartment except a kitchen or a parlour, we are driven to the conclusion that it is a work of necessity to make the photographer see himself as others see him; assuredly he must be made to feel that distempered rags and plastered boards do not a picture make, and that what is wanted is not the introduction of a new background or accessory but the infusion of new thought into his theory and practice of the profession of portrait maker. I have had many a good laugh at our studio properties; indeed, I have seen so much of the humorous side of the business and have found so many stodgy fellows in the trade that I have come to the opinion that they need to be shaken up a bit, and made to laugh at themselves, their work and methods, the little ways of clients and the world in general.

There may be said to be two ways of judging an accessory or background—its resemblance to what it purports to be, and its suitability or otherwise in conjunction with the subject. The seascape might be a good piece of work, but a lady in evening dress with the waves about to rush over her ankles would not be quite happy. The inlaid escritoire is probably good furniture, but it is out of place in a corn field with a sailor standing by. Let us consider intrinsic values, and then relativity in accessory and background.

Pieces of furniture in use in the studio are invariably of two kinds—ordinary chairs and tables of a drawing room nature, and seats, stools, fancy tables, etc., which are never met with outside a photographic studio, which are seen in nearly every gallery, the pious belief having been sedulously fostered that the manufacturers have specially designed expensive and uncomfortable furniture to make easy the work of the portraitist. There seemed to be more honesty in the old days, for we spoke frankly of "the posing chair," with its different backs and detachable arms. The "posing" was limited by the combinations of various padded parts, and we were quite satisfied that nowhere else but a studio could there be found anything like this chair, unless possibly the shop of an unsuccessful country barber. The words "swank" and "camouflage" were unknown in those albumen days; Smith and his rival, Brown, had the same mounts, the same paper, the same collodion enamelling or burnishing, and, of course, "the posing chair." Standardization and conformity were guiding principles then, just as individuality and originality are commendable qualities to-day. Undoubtedly there are scores of photographers professionally engaged at the present time whose work can take a proud place in the world of art. But is the average practitioner, with all his magnificent resources, anastigmat lenses working at large apertures, studio cameras with movements controlled by a simple touch, plates of phenomenal speed, unlimited light of supreme actinic quality at hand at any hour, is his average output far removed from that of the posing chair epoch? Unhesitatingly, I say that with all his opportunities the results do not favour the modern. Immediately, I am only concerned with the consideration of accessories and backgrounds. I wish to point out that, instead of bringing delightful variety into our work, a heterogenous collection of posing material has actually defeated the object for which, ostensibly, it was created, and that the average work to-day shows no advance whatever on that of thirty years ago. And the criminal could put the photographer into the straight path of artistic regeneration, for it is largely a matter of accessory.

As the Snapshottes make a distinction between studio furniture and accessories, we will first consider those pieces about whose function there is unanimity, the things of lath and plaster and papier mâché. The garden seat is a pretty firm favourite. I do not remember any time in my life when I sat on a stone seat, unless it be when I caught cold sitting on the wishing chair at the Giant's Causeway. I understand that stone seats may be found in the old-world gardens of magnificent estates, but my ducal friends will never persuade me to experience their discomfort. A studio stone seat, being wood, is less unkind to the person. I must say I prefer it to the lighter make of "garden seat" with open spaces nailed together, for the stone variety makes an excellent table for a quick lunch, but to spread a paper on the ribbed style is to court disaster when laying down your cocoa hurriedly to answer a foolish intruder. You may say there are other uses for garden seats; and that is correct, for, when hanging backgrounds or adjusting blinds, they are more suitable than Chippendale tables to stand on. Longfellow, in "Hyperion," writes delightfully about ruins. A stone seat has no dignity until it is a ruin. It is at its best when it is moulting, and going bald, when decrepitude has gripped it by the knees, and Time (or a mischievous child) has rotted away the nose of one of the gargoyles in whose mouths, in times of war, Tommies were wont to stick their fags.

If you have to take a group of persons in holiday garb, I can see nothing wrong in the use of the stone seat, if a good outdoor scene is used in conjunction, but for goodness' sake don't take the clumsy thing into the conservatory.

Let us look at both sides of the question; turn the seat round, and we are confronted by a bridge. Surely there never was such a diminutive bridge, barely 4 feet in length, and built of stone withal, the interstices having been so carefully plastered to resist the ravages of the years that one instinctively wonders what turbulent Niagara or seething cauldron is spanned by this arch. But the bridge starts from nowhere, leads nowhere, and sitters are generally posed in front of it, for it only spans the studio parquetry (linoleum). The bridge is seen at its worst in the library; let us, with stony indifference, leave it there.

Independence and an air of detachment seem to be the outstanding characteristics sought for in accessories—bridges with nothing to bridge, gates hinged on space and opening on cumulus clouds, marble pillars isolated on the sea shore, and the baby seat in the middle of the high road at the mercy of char-á-banc and cow. Even when linked up into combinations, there is little *esprit de corps* among the component parts, stone walls disclose brass hinges, balustrades which detest pretence, and threaten to give us away, have to be kept upright with plate boxes and Houghtons' catalogue.

I have lived years in France, but I was unfortunate with the windows there; they were nothing like the real "French windows" I had to manipulate when an apprentice in this country. In studio practice the window is, of course, on its own; a wall on each side would destroy the illusion. I have known a cranky worker who introduced side wings with his window, but the curtain, which was placed at the left side, true to tradition, gaped at the join, and the oak panelling

(simulated on canvas), the bulwark of the right flank, was squeezed so much into contact that the panels looked like spirals. Luckily, most photographers are not such sticklers for realism. In France they have glass in their windows, a fact which our photographers seem to ignore, for hands are always placed holding the sash in an impossible way if we are to think of it as glazed. Whether a lady is looking out of the window or looking into the room is difficult to fathom, the background last in use being usually employed. We all know that a figure silhouetted against the sky and gazing into a comparatively dark apartment would be all in shadow, yet we never see window studies in that key; one may also be perturbed by the problem of where the camera was that took a picture outside the *quatrième étage*, but that is to be too dashed particular.

There is a piece of furniture beloved by photographers which seems to have no name in the English language. I call it the four-legged tripod, and that's about the nearest I can get to a description of it. Women are supposed to stand at this flimsy affair reading Kodak's monthly, or threading paper daffodils into a sixpenny vase, supremely unconscious of the surroundings. I have one of these pedestals in my own studio, but its number is up. I had it hidden away, but my ambitious assistant, George, ferreted it out, and I haven't the heart to kick it to bits. I drew George's attention to the fact that one leg was falling out, and the well-meaning ass went and glued it up beautifully, instead of making it a complete cripple. One dark night I will remove the offence, for a namesless piece of furniture, flimsy and angular and cheap, which may be seen in thousands of showcases, ought not to be used in any progressive studio.

Hundreds of books have been written, and endless controversies waged round the subject of Hamlet's mentality. There can be little doubt about his state of mind, for a youth spent among Hamlet stools would make anyone dotty. Happily, his sojourn in England in pre-studio days restored his health. Nowadays he would be in Colney Hatch in a fortnight. I am not a culchawed person, and I plead guilty to knowing nothing about Looee Catoars or Loosee Sez or the Jackobeans, and really don't want to know anything about them. Some people object to you mixing your drinks, and others to mixing your furniture. I am easy both ways, but there are limits to everything. Stone seat, oak chair (showing large brass screws where the arms are detachable), Sheraton table, and "grouping stools" which seem to have been made from cigar boxes, make a combination frequently seen, but never in perfect harmony. It all depends what we are working for. If we are looking for fun the elements are certainly there. When I was twenty I was assistant to a well-known firm in the South of Ireland. Our clients were very good people, but periodically we had droves of rustics for whom there were special lines. The great favourite with the country folk was a full-length portrait on a 10 by 8 plate, from which cabinets were also printed. Well, the operator and I used to have competitions in complicated portraiture with these simple peasants. "I beat you yesterday" G—— would say to me, triumphantly, holding out a negative from the washing water. Then we would start counting the accessories, every chair, stool, plant, book, vase, rug, firescreen, magazine, boulder and pedestal counting as one. I didn't often win, for G—— took an unfair advantage by working a short focus lens and throwing in a view of the studio, with Noak's arks, toy horses and dolls disclosed at the sides. We never had any complaints; doubtless the customers thought they got good value for their money. These were the days of small waists for women. The negatives were generously treated with opaque and the figures "improved." This custom led to another competition, but when the waists actually got smaller than the necks of the sitters I left. I take it, however, that most times the photographer is only interested in the humorous as a side issue, his first concern being sound portraiture. If you cannot take sitters without numberless accessories you are still unacquainted with the pictorial possibilities of the human form. After all, the accessory is *not* the fact; it may be regarded as a necessary evil, but when employed it should be with discretion and taste, and not in such manner as will bring ridicule on our work.

J. Effel.

LOST BUSINESS.

Some time ago I said something in these pages about amateur opposition to professional business. I mentioned at the time how happy snappers were responsible for quite a lot of portraiture and other photography, which would have gone to the professional had there been no amateur to do it. It would have gone to the professional in any case, I think, if the average professional catered for it "loudly" enough; but, as it was, it was lost business.

Since then I have had many other examples of the same thing brought to my notice. Running a concern which caters largely for "D. & P.," I have seen more wedding groups this year than I ever saw before. All by pocket-camera "experts," who did it for the fun of the thing. But they afterwards spent, in the aggregate, quite a respectable sum on prints. And I believe that this amateur photography of weddings *does* affect the professional chance, though some are of opinion that if "contracting parties" want a real photograph they will go to a studio no matter how many snaps are taken. One experience of mine at least is evidence against this assumption. I queried a bride-to-be about taking the group, and was told that there was no intention of engaging a photographer, "as there would be no necessity. So many of the guests had cameras, you know." The only argument here is the one of quality. A good professional study is not to be displaced by any random snapping, but unfortunately the good study is not always in evidence, and some snaps really have a lot of good points.

Another case that came to my notice was one in which an estate agent required a series of photographs of houses and other premises which were in the market. The whole issue was done by a "snapper," and not only that, the prints which were used for advertising were not turned out by a trade finisher, but printed on self-toning by the taker.

The foregoing case is put in the shade, however, by the firm of furniture manufacturers who periodically handed a spool to a certain dealer. These spools, when developed, showed various pieces of new furniture "photographed" against a backyard wall, partly in focus and partly out, distorted and "colourless." But, bad as they were they continued to appear at intervals.

Machine photographs by amateurs are not at all uncommon. The negatives come along for painting out or enlarging. Sometimes they are really good, but they are never equal to the work of a man who does this sort of thing for a living.

Home pictures and home portraits, as might be expected, are very common subjects with most camera users, but I doubt if the professional who complains of slack business realises the amount of money spent on these items. At the present time there are many tracts of our time rural district which are now covered, and being covered, with corporation dwellings. These places are not invariably such as to incite the photographic instinct, either business or amateur, but nevertheless the majority of the dwellers therein appear to want their walls and gardens pictured, to say nothing of themselves and their children. Much film has been used this summer on these same walls, etc., and the most of it with lamentable results. I suppose that many

of the new suburbanites are also new to snapshotting, but they are certainly anxious to see themselves and their new homes on paper.

And home portraiture proper is becoming an item with amateurs. I was recently asked if I could produce "real professional pictures" from some film negatives which had been taken by young ladies in their boudoirs. As these were fairly good I said I could—at a price. This is, of course, quite legitimate business provided there is no cutting, and in this case there was no objection to the terms I quoted. The results—after a little retouching and enlarging on a carefully chosen paper—elicited the remark that "They were every bit as good as the best studio productions, *but much more lifelike*." Now there is something to make one think here. As regards the first part of the comment, well, I served many years in studios in my time and suppose that I ought to be able to make a "studio production." But the lifelike quality was due entirely to the fact that the sitters were taken under such intimate conditions, each one by her own bosom friend. There was no professional business atmosphere about it. But—and this is a big but—had the same negatives been on half-plates, and exposed by a professional photographic artist, they would have been much better in many ways, and, consequently, what were at the most good portraits would have been works of art as well. But, you may say, that would have brought in the detrimental "business atmosphere." Not necessarily. It would depend on the photographer. One may be a stranger to a customer, but it is quite possible to be a pleasant stranger and get along with him or her as easily as if one had been known to the person for years. The actual business would be done at the initial interview. The business atmosphere need not be carried into the studio or the customer's home.

Much of the photography I have spoken about might be obtained by the professional if he cared to seek it, and the last incident I shall mention is intended to illustrate this. But before proceeding, there is a point which I should clear up. Catering for amateur business I ought perhaps really to encourage the amateur rather than the professional. But there is photography which the amateur can do and photography which is best left to the man whose business it is. I do not believe in encouraging tyros to waste film on interior architecture. It does not do them, the profession, or the trade, any ultimate good. And I do not ask any professional to compete with the snapper on Blackpool beach or at the profitable—to me—charabanc picnics, which provide dozens of spools for "six of each." The professional can go after both if he likes, but it is the better fields where he is legitimately wanted.

The final case I shall speak of was one where a young lady entered a pharmacist's shop to borrow a camera. It was wanted to photograph a "spread"; in other words, a table laid out for a large feast. The counterman asked a few questions, and very sensibly concluded that the job was rather too tall for the intending photographer. He then suggested that it would be much better to consult a real photographer first, and the lady, not knowing the slightest thing about it, readily took his advice. She came to me. When I saw the table, filling the room to repletion and resplendent with colours—edibles, pottery, and floral effects—I sent back hurriedly for panchromatics and the shortest of short-focus lenses. Even then it was difficult to do justice to the job. The results, however, gave satisfaction all round, my return being a small but well-paid order. Had the young lady been left to her own amateur efforts the result would have been disappointment to her and her friends, and probably a shilling or two to the trade.

There is a type of amateur to whom the above remarks cannot be applied. It is the genuine serious worker who may have a penchant for a particular class of work. If such a one be fascinated by the "joys" of machine photography the chances are that he will obtain some excellent negatives, and if engineering friends of his take advantage of his ability we can only regret it. Certainly, in such cases, his dealer cannot be expected to discourage him. His case is totally different from that of the snapper who dabbles in things that are beyond him. At the same time the professional is always at liberty to let engineers and other business men know *his ability* to his own business advantage. The lost business that is being played with by other than professional camera users is not so much due to the amateurs as it is due to the general ignorance of professional ability and of ways and means by which to employ it to advantage.

THERMIT.

ART IN THE FURNISHING OF THE RECEPTION ROOM.

[Among the demonstrations arranged at the last Convention of the Professional Photographers' Association of America was one by Mr. Ross Crane, of the Art Institute of Chicago, on the application of principles of decorative art to the planning and furnishing of studio reception rooms. It was evidently a very effective demonstration, for the speaker was able to show in an actual room, the merits of artistic skill in the arrangement of furniture and choice of colours. In front of his audience he re-modelled a reception room by choosing fresh pieces of furniture, re-arranging and changing accents of colour. In the absence of this exhibition, the whole of his talk, as reported in the official minutes of proceedings, cannot be printed with advantage, but, in the abridged form which we give, the discourse will be seen to contain a great deal of good advice on the furnishing of a part of the portrait photographer's premises which very often could do with much closer attention, from the decorative standpoint, than it receives.]

WE started out from the Art Institute of Chicago six years ago to promote art. We had for our slogan, "Take Art to the people and the people will take to Art," and we found it true, absolutely true, but we found we had to take art to the people into their very homes, into the design of the paper on the walls, the rugs on the floor, and the furniture in the room. And we had to teach the world—here in the Middle West, anyhow—that Art was not something alien, something to be used on rare occasions, or for the lecture class, but that it entered into the useful and daily avocations of life, and we had to show it in the building of a house and the furnishing of a room and in the harmonising of the house with its surroundings—landscape art, and in the building and planning and designing and beautifying of the city—civic art or city planning.

Since I accepted the invitation to make this demonstration, I took it upon myself to visit photographers' studios and I have found varying conditions, just as you find going into our homes. One home is very beautifully arranged, and in the next one, in a house fully as elaborate and pretentious, I find an absolute ignorance of the laws of home furnishing.

I took some notes of one room for a reception room of a photographer who had been at least thirty years in the business in a large city, doing a pretty good-sized business, but not of the highest class, and he called my attention to the beauty of his rooms.

He said: "This is my studio," and I saw that he had in mind those cosy corners we used to have—some of you can remember, a Turkish cosy corner. He had a room in which the walls were in buff, and had thin panels of cherry mahogany strips all up and down, and a plate rail—relic of bygone days, which was a harbour of refuge for all the miscellaneous junk he had been able to accumulate in the thirty odd years.

On the floor were two Oriental rugs. Now I like Oriental rugs, and I use them, but these were not the right colour. They were red. There are varying shades of red. I have red in my curtain here, and on the couch, but these were the most violent, virulent, poisonous red you can imagine, on the floor, and they shrieked and yelled at everyone that came into the room. They disturbed me.

And for furniture he had quite a miscellaneous mess. All the

kinds of furniture that had been the latest thing during the last thirty years. There was golden oak, and he had gilt furniture, Chinese teakwood furniture, and some furniture of this period, and some tables, a roll-top desk in light oak and a swivel chair. He had one plush-covered chair and two chairs of the style of Charles the First—high backed, rococo, very elaborately decorated. There was no arrangement. He had two bronzes in the room. Now I believe that in a photographer's reception room there should be some evidences of whatever art may acceptably be brought into that room—pictures on the wall. I believe in a piece of bronze or a piece of statuary of some sort. This man had a bronze dog. I don't know what period that dog belonged to, and also one of these busts of an Indian girl, I don't know her name, but done in high colours; you buy them for $1.75 in any department store—in the basement.

And he had art upon the walls, and the pictures on the walls—his own products—were scattered without any arrangement at all, or any feeling of design—here and there—miscellaneous in its effect and very disturbing to the mind.

Now I speak of this one, not because it was so very bad. It wasn't as bad as some, but because of the fact that the man was so well pleased with it. He said he thought it was noble, and I couldn't tell him anything at all. I looked at it, took note of it, and said: "Where *did* you get so many things?" That was about all that I could think of.

And in the same block I went into another studio in a reception room which had all the qualities that this one lacked in fine restraint, in comfort and dignity—a room which I felt very sure represented very happily the thing that that man wanted to have people believe him to be, whether he was or not, and the chances are he was, because every room, whether it be a room in your own home, or reception room or gallery, is a confession or taste—if you have anything to do with it, it is a confession of your taste.

Photographers ought to be artists, and many of them are, but not always do we know how to apply those things we put into our pictures into the furniture of our room.

Suppose we start at the very beginning, the mental processes. I always ask myself, when I approach the problem of furnishing a bedroom or dining room or living room or photographer's room, this one question: "What is the thing for? What do I want to do? What is the thing we are trying to do?"

Now I am not in professional life nor commercial life, and, maybe, I haven't fully got just the idea supposed to be embodied by a reception room for photographers, but I believe it is a fine sense of comfort and dignity. Those two things. A little more formal than a living room in your home; in a reception room, you want a feeling of restraint, of dignity, *plus* comfort. People have to sit there for a while. Patrons come in and have friends with them, and while the patrons are getting ready for their operation, their friends remain in the reception room and look at anything they may have to look at.

I believe that the walls of that room might be used, and ought to be used to show forth some of the samples of the photographer's wares, but I don't believe that that is the place for most of it. I believe there we should employ the principle of restraint, and upon the tables we will have albums and portfolios containing a larger number of the photographs, samples of your work.

I want restfulness in that room. Restfulness is a part of comfort, always. You cannot be comfortable unless your mind is at rest.

Suppose you look at the furniture first. You have on one side a very beautiful Italian brown walnut cabinet desk, one of the most lovely things I know of, very appropriate for such a room as I have in mind. I have seen also desks of that type in walnut and oak in the Jacobean type, which fits in very well with that, and I have seen those in some of the reception rooms I have visited. The Jacobean type of furniture is used in the desks and the table and the chairs for the most.

We have in this room, besides that piece of brown walnut, some red mahogany. Now those two colours do not harmonise. I have nothing to say against this colour, but I believe that when you have that colour in one piece of furniture, it ought to be embodied in almost all the other pieces—not necessarily all of them.

That chair is of an altogether different period and colour, and this antediluvian monster here, this comes down from the Stone period. It takes up too much room in the first place, and, by the way, let me say, I am showing here a larger room than I have usually found. Sometimes I found a larger one, sometimes very much smaller, but the principles embodied can be applied to any other room.

We have also a little pedestal here of the golden oak period, which does not harmonise with anything in this room, and more than that, it is not suitable for the purpose for which it is intended. A pedestal is meant as a foundation for a bowl of flowers or for a piece of statuary, but this is very wobbly, and when I look at that I begin to wonder how soon somebody is going to knock it off and I cannot feel at rest in that room. Now there are pedestals made larger than that, with four legs, that I think are admirable and are to be used in a reception room. Flowers are not always available; they cost a good deal of money. I think in a reception room there is no reason at all why you shouldn't have a pot or two of flowers growing, provided you have any sunshine. Many reception rooms have no sunshine, and then flowers are a rarity.

We have different colours in our room. We have mulberry in the draperies and a dark mulberry in the couch. Then we have blue in this chair and green in that, and many colours. The things are rather a mess. The pictures on the wall are very well hung, but do they not relate to anything in the room; they are just put on the wall.

One of the fundamentals in hanging pictures is that a painting or a picture of any sort on the wall in a living room, at any rate, should be related to some other piece of furniture under it or near it. We put a painting over a mantelpiece, a mirror over a desk, or over a consol table, and so I find that by grouping pictures in a reception room, in groups, we get a very much more interesting result than by putting them haphazard upon the wall.

That couch is a beautiful thing, you cannot all see it, but I am going to show it to you by and by, and it very well relates itself to this piece of furniture over here—the Italian desk. This chair belongs to the desk. It is absolutely in keeping with it in every way possible.

Then we have here another type of chair, which we call the Austrian bentwood chair, which admirably fulfils a certain mission. You cannot wear it out; you know how durable they are, how well made, and how cheap, but really, that chair does not belong side by side with this. They don't belong to the same period; they are not of the same kind of wood; they are not of the same design nor spirit, and they really swear at each other. You have got to have harmony.

Here is a table which is very good indeed. It belongs to the so-called Colonial period, but it doesn't harmonise in colour of wood with my desk nor with my couch, nor that chair, and I assume that our photographer who started out to furnish this room did it by degrees; that he first had this, and this, and this. Then, suddenly, in a fit of extravagance, he bought that beautiful desk, and now he is ruined absolutely. He has got to go on now and live up to that desk. He bought the couch afterward, a very lovely couch, but having one couch there was no necessity for two. This little settee is absolutely unnecessary, and I assume that he is going to eliminate some of these others and bring in new furniture; that he has a sudden accession of prosperity. I don't know how he got it, but I want to say that the furniture I am using is a little more expensive than I think I can ever have in my own home, but the principles involved in the arrangement and in the association of the various pieces are the same whether you use Italian furniture or Jacobean or Colonial or any type. The principles are the same—the principles of arrangement and colour.

Before I can get to talking about colour and arrangement we will have to eliminate these pieces I spoke of. Even this table. I think they are going to take it home and put it in the living room because it is a very good table for that purpose.

Before we take it out, will you see the angle at which it stands? I have the desk against that wall; I have the couch against that wall, flat. The first principle of arrangement is that the rug on the floor and the large pieces of furniture ought to follow the structural lines of the room—the architecture. This room is supposed to be a rectangular room. We flared out the walls on either side so the people on both sides could look into the room, but for all purposes this is a rectangular room, and in order to get order, which is heaven's first law, we must follow the architectural lines of the room. The rug on the floor must be parallel to the wall. If you have two rugs they must be parallel to each other and to the walls, whether the rugs are large or small the same principle applies. If you want order, you can only get it by following the structural lines of the room. Our desk belongs against the wall and so does our couch. But here is one piece of furniture that swears against all other arrangement. It is on the diagonal. A great many people do this. They put the couch across the corner and the piano across another corner, but you cannot get order that way; you cannot get a feeling of design that way. So

we will eliminate this table, and these chairs I have spoken of and the settee, and I will hold these albums until we find something else that we can put them on.

Now we have brought in a table of a different type; a table which harmonises in colour of wood and in mass with that desk. You see how very much alike in the colour of the wood and in the turnings they are? Here is another piece of walnut, a little darker than the first, but of the same general type. We will put that against the wall. We will take out the settee and the little stand. We want the waste basket, it belongs here. We put the table on a line parallel with this wall. I have a wall here in front which is imaginary, but really as active as any other wall, and here I brought in a chair for colour and lines. Now we will begin at the beginning.

The two great keys to the world of beauty are colour and arrangement. Colour harmonises and unifies discordant elements. By arrangement you can take rather commonplace furniture and get a very fine and distinguishing effect, knowing the laws of arrangement.

In the matter of colour I find very many living rooms and very many reception rooms are absolutely at fault. You need one dominating colour always. In this room we are going to use a warm tone—mulberry. I have it in my draperies. I have it in the piece of upholstery; in the lamp, in the couch and part of the table cover, and some of it in the very wood of the furniture. We will call our colour for this room, then, mulberry, but we will have as a secondary colour, blue. They go very beautifully together. One or the other, either one, may be dominant.

I remember my first experience in handling colour in a living room. I was a student in Boston at the time, studying painting, and some of my relatives were about to furnish and remodel an old house, and they said: "We will ask our cousin, he is an artist (they thought I was an artist because I was studying painting), we will get him to decorate the house for us and it won't cost us so much." If they had only known how much it was going to cost them! They had to do it twice. They had to pay for my first lessons in interior decorating. They didn't know it, but they did.

We started out with the idea of colour. I found a large room—a library—facing on the north-east, not much sunshine, and I said: "A warm colour is indicated here" (speaking like a physician). Now, what are the warm colours? Well, red. Everybody knows that, so I said: "We will use red." Now if I had only gone a little further and thought of yellow it might have been very much better, but we took red. We put it in the wallpaper, on the walls, all over that room, and a library it was, but after we got that wallpaper on you couldn't see the books, and you couldn't see the people in the room, because they wouldn't come in there. Shut a sane normal man up in a room in which all the wallpaper is dark red and how long do you think it would be before he would be applying for admission to an insane asylum?

But I learned my lesson—that the deep colours and the strong intense colours are not for the large room. The first law of colour is the larger your space or area the less intense your colour ought to be. For our walls I believe a tint of colour—a tan or a little brown or a buff, or a grey, or putty, or cream, or delicate strawberry or gold. Many of those colours—and there are many of them—but not very violent. The larger the space the less intense the colour should be, and that applies also to the floor. The floor should not be violently coloured nor the ceiling. Here is a law you can put into effect anywhere—that the darkest part of the room should be the floor, and then the ceiling the highest value and the lightest colour, and the walls should be a middle value and colour. That is simple but psychological, absolutely, founded upon human experience. The floor is a background and a foundation also. It should be the darkest part of the room.

The second principle of colour is the less space the more intense the object may be. In some small object like candlesticks or candles or cushions we can have very brilliant colour. I think of the wall as the background on which a painter splashes his colours, the colours being in the smaller things. That is very natural and very likeable.

Now for arrangement. I have given you the first law of arrangement. That was about the rug and large pieces of furniture following the structural lines of the room. There is a second principle which comes in constantly, and that is the principle of balance. Things that are related to each other ought to balance each other. You will observe that we have here a fine quality of balance, a formal or bi-symmetrical balance; in the very centre we have the large tapestry. I must explain that that tapestry was not to go horizontally, the design shows that, but because I could not, in my hurry, find another of that size to fill up the space, I took this one as it is and turned it around—I have taken an artistic licence. Underneath that tapestry is a davenport which balances the centre of the stage, and then this table I have placed out in the middle of the room so that the centre of the table shall about centre on the middle of the tapestry; if I move the lamp over you find I have destroyed the balance. It should be in the middle in order that you may feel at rest about it. If I move the table a few feet to the right or left, you will begin to wonder when I am going to push it back where it belongs. We have that innate sense of proportion which Emerson said is the divinest thing in man, which makes it necessary for our comfort to have things balance each other.

I have on this side of the room a large mass—a high cabinet and over that a mirror and flanked on either side by pictures and by chairs, and I need something on that side to balance it. The large pieces of furniture and the high pieces of furniture ought not to be on one wall. They ought to be on opposite walls. Now manifestly we cannot always have cabinets that reach up high, but we can have what we call "built-up" effects. There is one we have here—the cabinet and the mirror above it, joined by book ends with the books between. On this side we have a small table which we brought in for the purpose of holding some of our albums, and we have used it as a foundation for another built-up effect, using for the centre that large black crayon picture, and connecting the table with that by means of a smaller picture underneath.

Now I believe a chair placed right here will help to fill up that space and give a sense, a feeling of design to the whole thing.

Back here we have on this wall some pictures which do not seem to have any relation to anything else in the room. I have planned with reference to these chairs. I think it is a very beautiful and dignified thing. It harmonises in colour of the wood and in the historical period with our desk, and couch, and with that table. It cost us quite a good deal of money, but not as much as you think. Those things have come down in the last few years—that is a thing of beauty and a very comfortable thing to sit in. We place it under that framed picture on the left of the room so the picture shall relate itself to the chair underneath it, and on the other side of the room we will do the same thing.

The reason why I didn't get two lamps just the same colour was because I couldn't. They weren't in stock. I would like to have had two lamps like that one on your right on either side of the davenport.

I will move this table aside so we can get the principle of balance embodied in this group in the middle. I have now one wall absolutely balanced, very well arranged for use. We have a couch in the middle with a tapestry above it that forms the centre of interest for this room.

Every room, whether it be a living-room or reception-room, should have one object of central interest—one centre of the light of that room—something that dominates the entire room. Sometimes it is a fireplace with a mantel shelf, with a picture above it; sometimes we have to build it up as we have here. You might have, instead of the tapestry, two high windows with the drapery forming the background for your couch. You might have, on the other hand, a room in which there is a window right here and a window corresponding to it here. The couch between those two windows, and over the couch, in place of your tapestry—because you won't want to have a curtain on either side and tapestry in the middle—you might build up an effect of your photographs—your framed or unframed photographs—in a sort of a composition, a large one in the centre, building it up pretty high. Let there be one part of the room that reaches up as high as possible toward the ceiling—here we have it—you see how very well balanced the whole thing is, the two lamps on either side of the couch, a little table on either side, and the chairs, forming a feeling of composition which is just as much a composition as anything you can put into a painting or into a well-planned photograph.

The feeling of design is something which, when you recognise it, appeals very deeply to everybody.

Now I will move the table back into the middle of the room, and we will pile on it some more of these samples. We now have ample room for circulation around the table. We have some albums and photographs upon these tables because this room was meant for that purpose—to show those things—and we have them available on every occasion. We might have some on these little end tables, so that whoever sits upon the couch can have some of these things to look at.

Out here we will want a chair. Here is a little chair that doesn't really relate itself to anything in this room in point of colour,

but it does in point of construction; here you have the Jacobean type, which is so closely allied with the Italian type. I should like to have had a bench here, but we happen to have this chair, and because it does not fight very much with anything else in the room—rather harmonises, and gives a little touch of colour—I will leave it here.

Now we have a naked place—a wall space that probably would be utilised by a window. I feel very sure that no reception-room will have so few windows as I have here. I assume that on this wall we have a window, and a door, but I don't know it. I am not quite sure about it, but we could have a window there to fill that space. Inasmuch as I haven't, I want to show the use of a screen as a decoration in a room. We will put that in the corner. A screen can be made by hand at a very small cost, covered with moderately-priced tapestry or rep or cretonne, and used perhaps for mounting one or two photographs.

I want to talk about the lighting. First of all, in a living room I advise using a light which is rather quiet and specialised—coming from reading lamps here and there and there, and with not very much other light in the room. A reception-room has a different function. I saw yesterday in a photographic studio a lantern made out of clear parchment, right up close to the ceiling. The lights were in that, and they did not hit you in the eye, but they did give a general illumination for the room which was very good, and the lantern was very artistic and pleasing.

In a reception-room we want more or less general light. It is very hard to get it out of order. You can move a chair around wherever you want to, but that room remains in order. As soon as you have that group over there where it is, and this group and that group arranged as they are, this room will remain in order. There may be too many lamps. It is not necessary, of course, to have all these lamps.

I think there is a feeling of dignity—rather formal, but not too formal. The couch—the easy chair here add the feeling of comfort and usableness that takes away the formality of the arrangement.

In case of windows—and we haven't touched much upon them—the window in your reception-room as well as in your living-room offers a very large opportunity for decoration. You should establish the colour scheme. The draperies in the windows offer the largest space. Windows, by reason of their conspicuous placement, reaching up into the higher part of the wall, offer a great opportunity for establishing your colour scheme in your draperies.

If you have a very small room be sure that you have no large pieces of furniture in the middle of the room. Keep the space in the centre of the room absolutely free, if the room is small. If the room is small, have the draperies and your sash curtains harmonise almost in tone with the wall itself, because then you minimise the feeling of broken spaces.

If the room is small and low, have vertical lines as much as possible; if it is very high use horizontal lines. The two laws that I spoke of, of colour and arrangement, have been applied here. Arrange the furniture in groups—always in groups, never a miscellaneous piece here and another piece there. There is never any feeling of design or satisfaction about that. A table and a chair—get them together.

The two fundamentals, then, are suitability and simplicity. The simplicity is not in the minimising of the number of pieces, but grouping of them to get the feeling of design, and get them in such relationship that they can be absolutely adequately used together.

Ross Crane.

PHOTOGRAPHING EXHIBITION FOWLS.

[A writer in "American Photography" suggests that good business for photographers is to be obtained by photographing prize fowls. Photographs of these birds are always acceptable to the illustrated journals dealing with the breeding and exhibiting of the fowls, while for advertising purposes the breeders themselves become good customers to the photographer. Postcards of young "chicks" are sent to likely buyers, while catalogues, showing the types of the older birds, are issued by many of the breeders. It is, of course, necessary to have some expert knowledge of the special points of prize birds, and the author of these notes suggests that the photographer should study the winning birds at the various shows.]

The growing interest in the breeding and exhibition of standard bred poultry has opened up a field for the careful photographer to cultivate. Large sums of money have been paid for individual specimens, and the selling of these birds by the specialty breeder brings to the man with the best knowledge of advertising the greatest financial rewards. The customer is reached generally by the use of photographs of the birds, reproduced in poultry journals or circulars. The business is almost entirely a mail order one, and birds are shipped all over the world.

An accurate knowledge of the breed characteristics is essential, as each breed has a distinctive shape. The photographer should, therefore educate himself, by a study of the winning birds at the larger shows, so that he can distinguish these details. The best method of working is to prepare everything before touching the bird at all. Fix the spot on say the head of an upturned barrel, where the bird is to stand, and arrange the background to suit the colouring of the bird. This should offer a contrast to the actual plumage of the bird, as by this means a better rendering is obtained. Focus the head of the barrel or stand and set the shutter ready for exposure. Some birds are much more nervous than others, and therefore the less they are handled the less trouble you will have with them. A profile outline is usually what is required in this class of work, so the subject should be placed at right angles to the lens. A gentle massage of the bird's neck and between the wattles always seems to be appreciated, and by slowly drawing the index finger under and away from the beak the bird's attention can generally be held long enough to secure an exposure with the shutter set on "bulb." A quick pressure and release, probably about 1-5th second, will be found ample. This will give a negative which will make good prints on soft paper, which is the best kind to use to show feather detail. The "bulb" exposure allows more latitude if the bird is of a colour or combination of colours that requires a fairly long exposure. After a little practice you will be able to hold the bird's attention, so that it will be absolutely motionless during the exposure, and the bulb can be released at the least sign of movement. The bulb should have ample length of tubing to allow you to reach the bird with one hand, and, at the same time, to be out of the lens field. Considerable work may be done in the winter by the use of flashlight. The birds are placed on a box or table, and some kind of background improvised, depending on the colour of the bird. Bear in mind when selecting the background that the comb and wattles of most birds are red and will photograph very dark, so it is a good plan to pose the bird so that these appendages have a little lighter background to show them off to advantage. For flashlight work only a small amount of any of the standard makes of flash powders is needed, half a teaspoonful usually being sufficient when an aperture of *f* 8 is used.

When using flashlight, the birds may be placed directly on the object on which they are to be photographed and focussed by the aid of a dim light. Cap exposures are best for flashlight work, and with the bird in position the lens-cap may be removed and the flash let off. Negatives should be developed with pyro-soda, diluted in equal volume with water. The plumage of a male bird is more glossy than that of the female, and reflections should be avoided by a careful arrangement of the lighting. Do not expect to sell a breeder photographs of his birds unless you have studied the breed and know the points which should be emphasised. A breeder may point out to you the special features of the bird, but unless you know the precise moment to make the exposure to show the bird at its best, you will make very few sales.

A. R. P.

SAFEGUARDING OF INDUSTRIES ACT: GALLIC ACID.

The following is the Referee's decision in the gallic acid case, already reported in the "B.J." of October 6:—The complaint in this case is that gallic acid has been improperly excluded by the Board of Trade from the lists of articles dutiable under the Act. Gallic acid was originally included in the list. Complaint was made of this inclusion, and the Board of Trade took it out of the list in the belief that it was covered by something I said in the tartaric acid case. There was not any real contest at the hearing before me. None of these persons who might be interested in maintaining the exclusion of the substance from the list attended to take part in it. I am satisfied that the usual notices have been given, and that persons interested have had the usual opportunities of giving evidence and of taking part in the argument.

I regret that no one of them has availed himself of these.

On the evidence of Mr. Hill and Mr. Rose and of the chemical journals and catalogues that were put in I find that gallic acid has been and is regarded by the trade as a fine chemical. I think, therefore, that the original inclusion of the substance in the list was right and that its present exclusion is wrong. The reason for this exclusion is the supposition that in the tartaric acid case I defined a heavy chemical as a commercial product mainly used for industrial purposes. It is said that as gallic acid is a commercial product almost entirely used for industrial purposes therefore it is a heavy chemical. So far from laying down any definition in the tartaric acid case of the terms "heavy" and "fine," I expressly decided that there was no scientific or trade definition of the terms, and that therefore the test was the trade classification in each particular case. The view that I intended to express in the tartaric acid case was this: There was no definition of "heavy" or "fine," but that in ascertaining how any particular substance had been regarded by the trade one would probably find that the purpose to which the substance had been put had had a good deal to do with its classification, and that for the most part chemicals mainly used, and used to a substantial extent in industry, had been classified as "heavy."

I do not think that this applies to photographic chemicals. As to gallic acid the total quantity used in a year is comparatively small, and I find on the evidence that the trade has regarded it as a fine chemical. Applying therefore the same test as that applied in the tartaric acid case I come to the conclusion that gallic acid should be included in the list, and I so award. No costs.

Assistants' Notes.

Notes by and for assistants will be considered for this column. Payment for accepted contributions is made on the first of the month following publication.

Planning the Workroom.

THE modern tendency is towards labour-saving contrivances in the way of printing and enlarging apparatus, but there is much room for study in the way of arranging such gear in relation to position of sinks, towels, and switches, to mention only a few of the points that are touched in the regular passage of work through the various stages.

Time and money spent in the intelligent arrangement of details which have as their object the smoothing of difficulties and the saving of fatigue and inconvenience to the operative will always be found to be at least as profitable, regarded as investment, as the cash laid out for labour-saving apparatus.—D. C.

Fleck Markings on Glazed Prints.

A very objectionable defect of glazed prints is that when taken off from the glass the prints show small flecks or surface markings, caused by the surface being too hard. This is generally brought about by immersion in too strong a hardening bath, or too long in one of normal strength. This causes the gelatine to re-contract after it has been on the glass a short time. The defect can be seen if examined through the glass, although quite invisible at the time of placing prints on and squeegeing, etc.

Some papers do not require any after-treatment if the fixing bath contains a hardening agent, but can be put direct on to the glass from the last washing water. During the war I even found it necessary to place prints in lukewarm water previous to glazing, so as to ensure a good gloss.

Another cause of these markings is too much pressure applied at the time of squeegeing, a fact which has sometimes had to be carefully demonstrated before people are convinced, since there seems to be an impression that too much pressure is quite an impossibility. The same effect can be seen upon examination, as already stated above. These remarks equally apply to ferrotype plates.—W. H. C.

Railways and the Camera.

A TEST case decided that railway companies legally could make no charge for carrying a camera which a passenger took into his compartment as his personal luggage. It may be worthy of note, however, that in case of loss or damage the company could disclaim any responsibility, while if the outfit were carried as luggage in the appropriate van they would be liable for loss or damage in transit.

Most photographers avail themselves at one time or other of the cloak-room to leave apparatus overnight, and although I cannot remember such a case arising, it may be useful to point out that no railway company will accept responsibility for articles so deposited above a value stated on the ticket unless a special fee is paid.

The advantage of a really good lock on a camera case hardly needs pointing out, especially as it seems extremely rare to find anyone taking the trouble to declare the value while paying the small extra fee.—D. C.

Mixing Chemicals.

WHEN a winchester of solution is made up, the general practice is to dissolve the ingredients in part of the water and to fill up the bottle with plain water. A shake or two is given to the bottle and it is stood on the shelf for use.

It is seldom realised to what extent the strong solution originally made is heavier than the added water. When juniors are entrusted with making up developers great stress should be laid on this, as many a seeming variation in output has been traced to neglect in thorough mixing of newly-made solutions.

If a bottle that has been made up a little while be inverted and held against the light, the intermixing liquids can be plainly seen. The violent shaking up and down so often employed is waste of effort because ineffective. The bottle requires turning upside down and back again steadily with a distinct pause of a second or two between each motion. Apparently slower, the result of a perfectly homogeneous mixture is attained in about twenty seconds.—D. C.

Exhibitions.

ROTHERHAM PHOTOGRAPHIC SOCIETY.

THE 33rd annual exhibition of the Rotherham Photographic Society was held last week, and was opened by Mr. T. W. Grundy, M.P. The president, Mr. H. C. Hemmingway, in a short address, said that having knowledge of the whole series, he could proudly say it was the best. To exhibit their own work might be regarded as egotistical, but here was a healthy rivalry engendered, and an encouragement to do better. They had confidence in believing that their yearly efforts had been of educational value, and filled one of the gaps in the social life of the town. The Society was affiliated to the Royal Photographic Society, and they were justly proud of the success of one of their members, Mr. Ralph Chislett, in his winning the blue ribbon of that organisation in one of the sections of nature work. The Rotary Club had extended a brotherly hand towards their modest venture, and it was possible that when the Club's survey scheme got going it might find a use for the Society's talents.

The following awards were made in the open section:—Class A (Landscape, etc.): Silvered plaque: "A Derbyshire Village," W. H. Hadley, Manchester. Hon. mention: "Old Whitby," E. Tinker, Sheffield, and "Peaceful Pastures," C. J. Unsworth, Didsbury.

Class B (Portraits, etc.).—Plaque: "Head Study," Sydney H. Wood, Darlington. Hon. mention: "Peggy," Ralph Jones, St. Anne's-on-Sea.

Class C (Architecture).—Plaque: "An Old World Corner," W. Bailey, Leicester.

Class D (Natural History).—Silvered Plaque: "Photo-Micrographs of Eggs of British Butterflies." Alfred E. Tonge, Reigate. Plaquea: "Lions." W. H Hadley, Manchester, and "Long-eared Owl at Nest," T. M. Fowler, Wombwell. Hon. Mention: "Woodcock," J. A. Sharpe, Lewes; "Arctic Skua Alighting," Ralph Chislett, Rotherham; "Herring Gull," Tom Taylor, Oldham; and "Garden Warblers," Thos. Robinson, Clitheroe.

Class E (Still Life).—Plaque: "Wendy," H. W. Howe, Harrow-on-the-Hill. Hon Mention: "Japanese Peonies," F. G. Tutton, Exeter.

Class F (Lantern Slides, Monochrome).—Plaque: "Gannett and Young," T. M. Fowler, Wombwell. Silvered Plaque: "Old Pewter," Ranald Rigby, St. Anne's-on-Sea. Hon. Mention: "Caterpillars of Moths," C. W. Colthrup, E. Dulwich; "Morning Mist in Lakeland," Victor E. Morris, E. Grinstead; "Gossamer—Spider's Web," A. S. Pye, Rotherham; "White Currants," A. S. Pye, Rotherham; and "A Careful Crossing," Ernest Tinker, Sheffield.

Class G (Lantern Slides, Colour).—Plaque: "Silver Birches," Walter Scruton, Leeds. Hon. Mention: "Fruit Study," J. W. Davies, Sheffield.

FORTHCOMING EXHIBITIONS.

October 18 to 28.—Portsmouth Camera Club. Particulars from the Hon. Secretary, C. C. Davies, 25, Stubbington Avenue, North End, Portsmouth.

November 4 to 11.—Bournemouth Camera Club. Particulars from the Hon. Secretary, 88, Old Christchurch Road, Bournemouth.

December 9 to 31.—Rochdale Amateur Photographic Society. Particulars from the Hon. Secretary, W. Lord, 10, Derwent Street, Rochdale.

1923.

February 5 to March 3.—Northern Photographic Exhibition, City Art Gallery, Manchester. Latest date for entries, January 12. Particulars from the Hon. Exhibition Secretary, Walter Johnson, 30, Hartington Road, Chorlton-cum-Hardy, Manchester.

March 2 to 31.—Pittsburgh Salon of Photography. Latest date, February 5. Secretary, Charles K. Archer, 1,412, Carnegie Building, Pittsburgh, Pa., U.S.A.

March 13 to 16.—Exeter and West of England Photographic Exhibition. Particulars from the Hon. Secretary, Frederic G. Tutton, 9, Union Road, Pennsylvania, Exeter.

March 15 to 24.—Photographic Fair, Holland Park Hall. Secretary, Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

March 1 to 8.—Birmingham Photographic Society. Latest date for entries, February 15. Particulars from the Hon. Secretary, J. E. Breeze, 178, Broad Street, Birmingham

Fashion Photographs.—A costumier's advertisement in the "New York Times" has as an illustration a triple photograph of a type once popular in England. The fashionably-clad damsel is posed against a triple full-length mirror, the photograph showing the model herself and three reflections, the mirrors being at different angles; the back, side and front of the costume are shown in the one picture. This plan might be revived by some of the present-day London photographers of costumes.

British Industries Fair.—The Board of Trade have commenced their publicity work amongst probable buyers from overseas, by the first of a series of letters, giving particulars of the many features of the forthcoming Fair, to be held from February 19 to March 2, 1923. A general illustrated booklet is being published in nine languages, and this will also be distributed throughout the world. The Fair will be held concurrently at London and Birmingham, the latter covering machinery, general hardware, etc., while in London, at the White City, the lighter manufactures (in which optical, photographic and cinematographic goods are included) will be shown. The spaces applied for are now being allocated. Any manufacturer who has not sent in his form should immediately communicate with the Secretary at 35, Old Queen Street, London, S.W.1.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications October 9 to 14:—

Apparatus.—No. 27,697. Projecting and photographic apparatus. V. Bridgman and S. Ormea.

Apparatus.—No. 27,924. Photographic and cinematographic cameras. S. Sullivan.

Apparatus.—No. 27,816. Photographic apparatus. H. B. Stringer.

Development.—No. 27,645. Photographic developing tank. G. F. Framjee and A. Waterworth.

Flashlight.—No. 27,733. Flashlight apparatus for photography. W. S. Crapper and B. M. Hillier.

Shutter.—No. 27,960. Photographic shutter with movable screen. Compagnie Aerienne Francaise.

Processes.—No. 27,590. Photographic processes. A. L. and M. Landau.

Processes.—No. 27,333. Photographic processes. Wadsworth Watch Case Co.

Cinematography.—No. 27,334. Production of cinematograph films, etc. E. C. R. Marks (Daylight Film Corporation).

Cinematography.—Nos. 27,923 and 27,925. Cinematographic apparatus. S. Sullivan.

Colour Cinematography. No. 27,308. Colour cinematography. D. C. L. Syndicate, Ltd., and F. W. Donisthorpe.

Colour Cinematography.—No. 27,953. Projector lanterns and slides therefor and means for producing animated pictorial effects in colour Kinemas, Ltd.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

Photographic Type-Composing Machines.—No. 186,255. (September 29, 1921.) The invention relates to a printer's composing machine, for photographically producing a negative of the printing surface for lithographic, offset, letterpress and photogravure printing. Matrices of either a negative or positive character are employed dependent upon the type of printing in view, and a type-setting machine, with the usual magazine, keyboard and distributor. A camera attachment is provided for photographing step by step the various lines, or portions of lines, when set. The complete block of matter is conveyed photographically by means of a beam of light passing through or from the matrix, and through a lens on to a sensitised plate or film. The negative obtained is employed in the usual way for preparing the printing surface for reproduction. The invention may be broadly summarised as a type setting machine similar to the well-known "Linotype," but the usual type-casting matrices are replaced by characters, suitable for reproduction by photography. In carrying out the invention means are provided for justifying a line, photographically by enlarging or reducing, to bring it to the required length. In conjunction with the automatic focussing is a centralising mechanism which shifts the camera lens laterally to compensate for displacement of centre in case of a long or short line. The guideway carrying the matrices to be photographed is formed with a movable part, so that each line, when set by the operator, may be automatically raised to photographic position in front of the lens. Various mechanical movements are provided for automatically raising a set line, justifying, exposing and moving the sensitised surface step by step, but these are capable of modification within the limits of the invention. It is proposed to employ transparent or translucent matrices of glass or equivalent, either negative or positive. These may be constructed of two superimposed plates of ground glass, the character being on an abutting face and the plates bound together at the bottom by a suitable metal binding. At the top the plates are mounted in a metal head, which may be cut with a distri-

buting combination similar to the combination used in the matrices of the well-known linotype machine. Alternatively, the matrices may be of metal bearing a black letter on a white ground or a white letter on a black ground. The slideway is fixed on a transverse vertical wall erected on the base of the machine. As each line of matrices is complete, it is moved to a central movable part of the slideway, and is raised in register with the shuttered opening of a photographic camera. Each line of type is photographed as it is positioned, by the automatic operation of the shutter on the lens working in conjuction with the movements of the slideway. A Bowden cable communicates from the shutter of the lens to a suitable position, terminating in means for synchronous actuation according to the cycle of the machine. After exposure, the line of matrices is moved along the slideway away from the central position for distribution to the magazine in the usual manner.

Any suitable light may be employed, the light being projected through the translucent matrices or on to the front faces of the opaque matrices, and thence through the lens. An arc lamp is placed in a suitable position, and its beam is projected directly through the matrix line or via any suitable mirror or prism system for reflecting the light. It then passes through the shutter to the lens of the camera. The shutter is regulated by a micrometer adjustment so that the requisite width of light strips are impressed on the sensitised plate or film. This adjustment is in accordance with the required line spacing, and the vertical travel of the plate or film line by line also works in accordance with the required spacing.

A photographic camera for use in combination with the foregoing consists of a vertical partition mounted on the base of the machine parallel to the shuttered aperture. This partition is constructed with a focussing jacket carrying a suitable lens. The partition is connected to the walls of the shuttered aperture by means of a light-tight bellows, and is capable of adjustment between the opening and a plate or film carrier. The rear of the machine may be built into a dark-room. In the rear of the partition is mounted the carrier for a glass plate, roll film, or sensitive transfer paper. The carrier supports are movable along the base, and the carrier is provided with a finer longitudinal adjustment working in conjunction with a justifying device. It may also be furnished with a micrometer screw adjustment to alter the position of the camera for correcting focus. The upper and lower frames are adjusted to take any size of plate within wide limits, and, by aid of racks, the plate is capable of vertical and horizontal movements for columns and other comparatively large initial adjustments. The plate carrier frame is suspended in suitable guides by a pair of cables running over pulleys on the main supports, there being counterweights so that the plate may be lowered by a ratchet movement line by line synchronously with each set line of matrices and photographic exposure. Suitable automatic mechanism to effect the periodic movement of the plate may also be employed.

A gearing is used to effect the proportionate movement of the supports carrying the adjustable lens partition and the negative supports together, so that various sizes of matrix image may be projected in accordance with a predetermined scale of enlargement or reduction of the matrix characters. Such movement is made and the members positioned as a preliminary to type-setting by the operator. A suitable indicator at or near the keyboard indicates the relative size of the images at various positions of the members.

The justifying and centralising movements work in conjunction with the rise and fall of the guideway. A cam withdraws a justifying plunger until the guideway has attained the high position. Through a quadrant the plunger is returned and presses against the end character in the line of matrices resting in the guideway under the influence of a spring. If the line is of normal length, the position of the plunger is such that an arm comes to rest in a position having no effect on the focus of the camera. But if the line of matrices is wider than normal the displacement of the plunger is communicated through the quadrant and arm to a cross rod. The latter has a cam device on an inclined runway which causes the bar to move toward the front plane of the machine. This moves two rods which are adapted to adjust the two carriers each its respective distance, and so alter the focus as to reduce the photographed image of the line to the normal length.

To centralise a reduced line the lens may be laterally moved according to the position of an arm. To accomplish this a connecting link oscillates through a pin and lever. The latter in turn partially rotates the shaft, and by a pinion moves a racked arm extending from the lens jacket. The pinion is keyed to the shaft, and travels along the same with the carrier. In the case of underwidth lines, a plunger moves beyond its normal position, and the arm again transmits the displacement from normal to the cross rod, causing a bar to be moved away from the front plane of the machine. Alternatively, a mechanical method of justifying short lines in type-setting machines may be employed by using wedges, which fit into the spaces of the composed line to the requisite amount, and expand the line as a whole to the normal width. Such a form is suitable for use with transparent matrices to engage the upper ends, and so permit light to pass between the words. With matrices of a negative character, a double-wedge space band is required to block out the light between the words, and with opaque matrices a double wedge spacer would be used, having its edge black or white, according to the blackground of the matrices. John Robertson, Thomas William Brown, and Andrew Orrell, St. Leonard's Road, St. Anne's-on-the-Sea.

The following complete specifications are open to public inspection before acceptance :—

LENS.—No. 186,917. Photographic lens. Ernemann-Werke Akt.-Ges.

CINEMATOGRAPHY.—No. 186,898. Apparatus for producing cinematographic pictures with relief effect. C. Parolini.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A meeting of the council was held at 35, Russell Square, London, on Friday, October 13, 1922. Present:—

Messrs. Marcus Adams, Angus Basil, Arthur Bennett, Frank Brown, W. B. Chaplin, A. H. LL. Chapman, Gordon Chase, T. Chidley, Alexander Corbett, C. F. Dickinson, W. E. Gray, Reginald Haines, George Hana, Herbert Lambert, H. A. St. George, R. N. Speaight, H. C. Spink, F. G. Wakefield, A. Swan Watson, W. H. O. Wedlake, H. D. Halksworth Wheeler, and the Secretary (Alfred Ellis). Mr Alexander Corbett in the chair.

Mr. Speaight proposed, and the reception of the proposal by the council was so hearty that there was no need for a seconder, that Mr. Corbett, the new president, continue to act as chairman of council for the ensuing year. This was agreed to unanimously. With the same unanimity Mr. Alfred Ellis was reappointed secretary.

The secretary reported the receipt of a letter from Mr. W. Illingworth, bearing the date October 12, confirming his decision, expressed verbally at the meeting of September 15, to retire from the council. The resignation was accepted, with expressions of regret and of appreciation for Mr. Illingworth's past services.

The vacancy thereby created on the council was considered, and it was proposed by Mr. Chidley and seconded by Mr. Wheeler that the Society of Master Photographers (Lancashire and district) be asked to nominate someone who was a member of the Association who would be willing to serve.

Mr. Speaight reported that there was a balance on current account of £33 13s., and on congress account of £30 12s. 11d.

A discussion took place on the subject of the next congress, and suggestions were made with regard to the suitability of different seasons, and the claims of a spring as against an autumn meeting. The feasibility of holding the congress in a provincial town was also discussed, as well as the possibility of holding a modified spring congress next year without an exhibition. The chairman suggested that a small committee be appointed to go into the whole matter and report to the council. The committee was appointed to consist of the following:—

Messrs. Adams, Basil, Chase, Haines, and Wakefield, and the chairman and treasurer *ex officio*.

Mr. Speaight presented accounts for the "Record," and Mr. Watson commented on the great amount of work the "Record" committee had accomplished. He quoted golden opinions which he had heard as to the excellency of the publication. He proposed and Mr. Frank Brown seconded that £100 be voted to the "Record" as a working capital. This was agreed to.

Mr. Hana brought forward the question of advertisements of German goods, and read three letters thereon. It was resolved on the proposition of Mr. Gordon Chase that he continue to act in accordance with the resolution passed on June 20, that all applications for advertisement space be considered on their merits.

Mr. Hana presented a list of commercial prices, and it was agreed that the same should be published in the "Record," and that they be copyrighted, but that permission for their reproduction be granted at the discretion of the council.

Mr. Wakefield reported on correspondence with the Empire Exhibition authorities, from which it appeared that the present holder of the photographic rights had them for one year only on a payment of 10 per cent. commission and a guarantee of £500. The question of the two guinea fee demanded for permission to photograph was to be taken up by the Manufacturers' and Dealers' Associations, and it was suggested that the P.P.A. should work in conjunction with them to protest against the unreasonableness of the terms of the monopoly. It was resolved that the secretary, with Mr. Wakefield, should interview Messrs. Houghtons, Ltd., on the subject.

The secretary also reported that no advance had been made with the Press Photographers' Association on the question of the action of art editors in taking single figures out of groups.

With reference to a letter from Mr. Tirrell, of Elgin, on the question of excluding photographers on a royal visit, a member said that the authority for such exclusion was generally given to the police, and the secretary was instructed to communicate with the police at Elgin on the subject.

Mr. Chase brought forward a simplified co-operative advertising scheme, which would consist in having display cards printed for placing in photographers' windows.

The chairman pointed out that this was not the scheme of co-operative advertising proper which they had to consider. The secretary read a letter from Mr. Beaufort, of Elliott & Fry, who suggested that any scheme should be in the hands of experts working in conjunction with photographers, who should be asked to send in their suggestions. Mr. Lambert moved and Mr. Adams seconded that the whole subject be adjourned to the next meeting, and this was agreed to.

The secretary read the names of sixty applicants for membership received since the last ordinary council meeting, and these were approved. The resignation of Mr. F. J. Arnott, of Lymington, was accepted, he having sold his business.

The council having sat for four hours, it was decided to adjourn the meeting until Thursday, October 19, at 6 p.m., when the London members promised to attend to consider the secretary's correspondence, which it had not been possible to take.

CROYDON CAMERA CLUB.

Mr. J. C. Coffin was announced to lecture on "A Dark-room Under the Tiles." Without wishing to belittle his, no doubt, independent discovery that this position is preferable to a location above the tiles, yet, unfortunately, he cannot claim to be the first and true inventor.

Apart from a recent discourse on "Duralumin," he has trod the boards but seldom, preferring the pleasing role of a general disturber of the peace. Let a fellow-member, whilst lecturing, apparently fall into error, and a smile of substantial elongation instantly adorns Mr. Coffin's face, only to come off at the first chance of getting home a real Mary Ann punch. This does not always land, and occasionally Mr Coffin has experienced being converted into an exceedingly appropriate container for himself.

The dark room transpired to be immediately under the tiles approached by a ladder, a position rendered compulsory after ejectment from a spare room owing to an addition to the family. Few would have the skill to erect such a well-appointed celestial apartment, but all listened with attention to full constructional details, supplemented with elaborate working drawings and many diagrams on the blackboard. He believes in comfort, and blow the expense, a Brussels carpet being on the floor to ease the feet, and thick felt on the solitary chair to soften impact. Even the sink is lined with rubber so that dishes and graduates can take things easily. Electric light, and a water supply and outlet, which viâ the gutter once gave a neighbour an unexpected and medicated cold bath, complete the equipment. No wonder the president, in proposing a vote of thanks, paid the lecturer a delicate compliment by saying that he confidently looked forward to far and away better work from him in the future. Mr Keane is always confidently looking forward to something or other in the desirable line, and if a kind friend would present him with a respectable pipe in place of his latest (apparently purchased from Woolworth's at ruling prices), it would be conferring a favour on those compelled to sit in the vicinity of the president's chair.

Prior to the start Mr. E. A. Salt, by kind permission of Mr. Coffin, made reference to a past observation of Mr. Jobling, that very full correction was obtainable on ortho' plates of the self-screened class, with filters of low multiplying factor, and showed a comparative and instructive test.

An exposure was made on an Imperial "Non-filter" plate without a filter, and another prolonged five times with a Wratten K 1½ filter in position. Both negatives were developed in the same dish for the same time to a degree of contrast about right for platinotype, and were printed for the same time. The prints handed round showed approximately the same printing value as regards general depth.

In the print from the first negative the foliage was nicely rendered and the tone representing a cloudless blue sky appeared to be fairly true. A church spire, of somewhat light hue inclining to yellow, was depicted as a dark object against the sky. In the print from the second negative the spire appeared as a white object against the tone of the sky, which was but slightly darker than its counterpart. The foliage here showed much lighter, and from his recollection of the scene appeared to be over-corrected. If so, a "correct" rendering might have caused the almost shadowless front bit spire to vanish altogether.

He also alluded to the non-halative properties of the new D.S. backing, which was liberally applied, and which, from trials made on the "Eclipse" ultra-rapid plates, he had found to be highly efficient. Many would remember that the letters "D. S." comprised the initials of a self-christened Mr. Windle, who years ago achieved notoriety in banking, and subsequently in legal circles, but he understood there was no connection between Mr. Windle

and the backing. Unlike some of its tribe, it appeared to be of a stay-at home character even when bumped about in metal slides, a very strong point in its favour. During the late stages of development it also permitted of inspection of the negative by candle light. Except in an emergency he regarded this procedure as a fatuous stunt, for a bright yellow safe-light in the dark-lamp obviously afforded far and away more light, with no risk of fog. At the earnest request of the president Mr. Salt then subsided.

Commercial & Legal Intelligence.

LEGAL NOTICES.—Notice is given of the dissolution of partnership of Wilfred Dennis Moss and Edwin Charles Peckham, trading as Moss, Dennis & Peckham, at King Street, Stroud, as photographic artists. Debts will be paid by E. C. Peckham.

NEW COMPANIES.

SCIENTIFIC OPTICAL SOCIETY, LTD.—This private company was registered on October 10 with a capital of £2,000 in £1 shares. Object: To carry on the business of opticians, manufacturers of and dealers in optical, mathematical, philosophical and photographic instruments, etc. The subscribers (each with one share) are:—W. H. Hawkins, 5, Medina Terrace, Hove, Sussex, director; E. J. Evershed, Thanet House, 231, Strand, W.C.2, solicitor; W. H. Hawkins is managing director. Qualification, 50 shares. Registered office: Thanet House, 231, Strand, London, W.C.

FRANK LESLIE (CHEMISTS), LTD.—This private company was registered on October 17 with a capital of £3,000 in £1 shares (2,000 6 per cent. cumulative preference and 1,000 ordinary). Objects: To adopt an agreement with F. Leslie, and to carry on the business of chemists, sundrymen, dealers in photographic, fancy, and scientific goods and instruments, perfumery and toilet goods, etc. The first directors are:—F. Leslie, 119, Ardgowan Road, Catford (managing director); Mrs. M. Leslie, 119, Ardgowan Road, Catford; T. G. Usher, 22, Merchiston Road, Catford. Qualification, £100. Remuneration, as fixed by the company. Registered office: 118, Rushey Green, Catford.

News and Notes.

THE LATE MRS. WALTER SCOTT.—We are sorry to hear of the death, after a very short illness, of Mrs. Walter Scott, wife of Mr. Walter Scott, of North Parade Studios, Bradford. Mrs. Scott took a very active part in her husband's business for many years, until failing health compelled her to resign these duties some three years ago.

THORNTON-PICKARD ENLARGERS.—A circular descriptive of their latest models of enlarging lantern has just been issued by the Thornton-Pickard Manufacturing Co., Altrincham. It describes a new pattern of enlarger, the "Imperial," issued in four sizes from quarter-plate to half-plate at prices (without lens) from £5 5s. to £8 17s. 6d. The list is obtainable free on application.

MR. EDGAR CLIFTON, whose wide experience of studio and other departments of the photographic portrait business is no doubt well known to many of our readers, informs us that he is now at liberty to undertake advisory work for photographers, such as the improvement of daylight studios, fitting up of artificial light installations, planning of workrooms, etc. Mr. Clifton may be addressed at 27, Hanley Road, Stroud Green, London, N.4.

MR. THOMAS ILLINGWORTH, after a business career of over thirty years, has resigned the managing directorship of Messrs. Thomas Illingworth and Co., Ltd., in which office he will be succeeded by his son, Mr. Thomas Midgley Illingworth. The well-known Willesden firm will, however, have the advantage of Mr. Illingworth senior's wide experience of the business, since he will remain on the board in the capacity of consultant director. We wish Mr. Illingworth every happiness in the greater leisure which his partial retirement from active duties will bring to him.

PHOTOGRAPHIC SURVEY OF BRISTOL.—At the annual meeting of the Bristol and West of England Amateur Photographers' Association, a resolution was passed in favour of making a more systematic and extensive survey and record of the city and its immediate environment. One of the arguments adduced in favour of the decision was that in a city of such proportions there were many architectural and geographical features that disappeared from time to time, and a photographic record of them would be of use, as well as of interest in the future. Mr. C. F. W. Denning, F.R.I.B.A., undertook the duties of secretary of the architectural section, and Mr. F. Beames, B.Sc., consented to act in a similar capacity for the geographical section.

PRICES FOR COMMERCIAL PHOTOGRAPHY.—The Professional Photographers' Association has no desire, indeed it does not consider it its duty, to control prices. There has been, however, a continued demand for knowing what are considered to be fair and reasonable prices for commercial photography. To satisfy this desire, a questionnaire was drawn up by Mr. George Hana, and hundreds distributed amongst photographers who did commercial work. The returns, which were beyond anticipation, have been collated and analysed by Mr. Hana and Mr. Jenkyn Griffiths, whose findings will be published in the November issue of the "P.P.A. Record." Average prices have been arrived at, and the professional photographer can adjust his prices accordingly. Copies of this issue of the "Record" are 9d., post free, from 36, Warwick Road, Earl's Court, S.W.5.

WALLACE HEATON AUTUMN SALE.—Messrs. Wallace Heaton, Ltd., 84, High Street, Sheffield, send us the 56-page price list of the autumn sale of photographic apparatus which they are now holding. Stocks of all descriptions of goods, cameras and lenses, have been further reduced in price, and include the stocks recently purchased from two well-known dealers. Messrs. Wallace Heaton specially point out the almost pre-war prices of their Zodel enlarger. It is now supplied in quarter-plate size at £5 10s. and in half-plate size at £9, in both cases inclusive of Petzval portrait lens. Since the list was issued Messrs. Wallace Heaton have further purchased the stock of a London and provincial dealer, and are offering goods, running into some thousands of pounds, at exceptionally low prices. These include in particular hand cameras of all kinds. It is evident that the intending purchaser of apparatus has in this sale the opportunity of buying one or other of the latest models of camera at a very advantageous price. The list is sent free on application.

OVER-ENTERPRISING PRESS PHOTOGRAPHERS.—Many of the newspapers last week contained a portrait of Dr. B. Hartzhorne, who is in the Royal Free Hospital suffering from sulphonal poisoning. The victim was pictured lying insensible in the hospital bed. The photograph has been severely criticised by the public, and its appearance is not likely to improve the position of photographers who work for the Press. A statement has been issued by the hospital, through the Commissioner of Police, with reference to the photographs, as follows:—"Two men, purporting to be Press representatives, obtained access to the hospital on the ground that they had received permission from Scotland Yard to photograph the patient. This statement was queried by members of the governing body of the hospital who happened to be present, whereupon the men gave up certain photographic plates which they had taken, reassuring these gentlemen emphatically that these were all the plates they possessed. They were then allowed to depart. On inquiry at Scotland Yard it has been ascertained that the statement made by these men was wholly untrue. The hospital authorities have always realised the necessity for securing the absolute privacy of the inmates, and regard the intrusion of these men as a disgraceful act."

PHOTO-MICROGRAPHY.—The sixth edition of the booklet bearing this name, and described "as an introduction to photography with the microscope," has just been published by the Wratten Division of Messrs. Kodak, Ltd., Kingsway, London, W.C. To the beginner in this interesting branch of photography, a volume, containing such a wealth of information, and covering all sections of the work, will be most useful, and should prove a great help in overcoming any difficulties that are likely to be experienced. The apparatus used in photo-micrography is fully described, and some interesting notes are given upon the light-source and the selection of a suitable illuminant. The obtaining of the necessary contrast when producing photographs of slides of lightly stained sections is fully explained, and illustrations are given to show the value of light-filters for contrast and detail. Some notes are included upon the Rheinberg system of differential colour illumination, a set of stops now being available for the process. The concluding chapter deals with photographic procedure, exposure and development being fully explained and formulæ given for the

various solutions. The volume forms a useful adjunct to the library of the photographic microscopist, and we are pleased to recommend it to all who are interested in this direction. The price of the booklet is 6d.

THE STORY OF A FAMOUS PHOTOGRAPHER.—The October edition of the American magazine contains the report of an interview with Mr. Pirie MacDonald, of New York. This well known photographer, whose subjects are amongst the best known men of the industrial and social world, gives some interesting incidents of his career. His first attachment to photography was as an assistant at four dollars a week, and his duties included all the dark-room work and the outdoor photography. For this liberal sum he also "took all the orders, kept the books, helped to make the frames, and bought the Christmas cards." In seven years he had saved fifty dollars, and with this as his capital he decided to rent a studio of his own. After many trials he managed to make his mark in the photographic world, and to quote his own words, "became an infant prodigy." He was in those days famed for his photographs of the fairer sex, and it was not until the year 1900 that he decided to please himself and devote his attention to the photography of men. "It is not sufficient to be, in technique, the most expert photographer in the world," Mr. MacDonald told his interviewer, "you must be able to make a portrait that will satisfy the people for whom it is intended. To do that you must give them something more than merely the outside of the face; you must give them the inner personality, and it must be the special phase of personality that is wanted in that particular picture."

Correspondence.

SOFT-FOCUS COMMERCIAL PHOTOGRAPHS.

To the Editors.

Gentlemen,—In your note on soft-focus commercial work, in the issue of the 20th inst., you remark that it is a difficult matter to work up prints in the customary manner when a soft-focus lens has been used.

May I point out that in America, where a large amount of soft-focus advertisement illustrating is done, it is the custom with, I believe, the majority of workers to make the original print with an ordinary anastigmat lens, then to work this print up as may be thought necessary, with lettering etc., included. A copy of this worked-up print is then made with a soft-focus lens, and a final print, which is entirely photographic, is put into the hands of the block-maker. Thus the very real difficulty of which you spoke is overcome.—Yours faithfully,

STUART BLACK, B.A.

1, Cary Place, Fleet Street Torquay, October 21.

DARK-ROOM LIGHT FOR BROMIDE PAPER

To the Editors.

Gentlemen,—A dark room worker of any experience worth having would vote a red light to be quite safe for any development paper, for which a yellow or orange light is advised. Many workers, however, fearing the unsafeness of a yellow light for bromide paper, do not hesitate to use a red one, and yet no maker of bromide paper ever recommends the use of a red light! For generations a yellow light has been advised for bromide papers, even for the most rapid makes. To those accustomed to the dim red light of the plate-developing room a yellow light may appear to be too "light," and fears of fogging may be entertained. If, however, fogging does occur, it will be because of exposing the paper to the yellow rays for too long a time, or, of course, to the admission of white light.

The point I wish to emphasise is that for bromide paper yellow light is very much safer than red, and it needs but a few trials to prove it. I scorned the idea when I first heard it, believing my informant to have "a bee in his bonnet," but the continual and mysterious fogging of a particular make of bromide paper led me to experiment. I then discovered that the paper fogged much more quickly in a red light than in one of the orthodox yellow. I had given up a yellow light in favour of a red because the high lights in my enlargements did not appear as clean as I liked them to be, but the red light gave me no better results. So sensitive to red was one brand of bromide paper during last spring that it was possible to get an enlargement through the ruby cap of the enlarging lens and within a reasonable time. Such being the case, one will realise how quickly the paper fogged when it was developed near to the red lamp of the dark-room. The same paper did not fog nearly so quickly when exposed to a fairly bright yellow light, while with two thicknesses of fabric in the dark room lamp fogging was quite unnoticeable.

So much attention has been given to the preparation of red and green "safe lights" for use with plates that the yellow one for bromide papers appears to have been neglected. With the extra-sensitive bromide papers now on the market it is a pity some enterprising dealer has not made a specialty of an extra "safe" yellow medium. It is when a yellow light is suspected that a worker is induced to "turn on" the red, and not always with the most satisfactory results.

All bromide papers have not this peculiar red-sensitiveness. One batch of paper, it appears, may have it, while the next batch may not. It is something that cannot always be relied upon, hence the care necessary when starting work with a new batch and the importance of keeping to a yellow light.

HYPERION.

BEHAVIOUR IN THE STUDIO.

To the Editors.

Gentlemen,—I always enjoy reading Mr. J. Effel's lively contributions, and agree with much that he has said, but I think he rather overstepped the mark in his contribution (on page 631) last week. He is too severe on the rank and file of studio workers.

I am not a professional photographer, but rather a looker-on, and as such can claim to see most of the game. I have called upon and sat to photographers ranging from the really third-rate man (who is to be found in the lower quarters of our great industrial centres) to the very best West End photographer, and I have never yet met an operator so woefully ignorant as he imagines the tribe to be.

Your correspondent italicises the story of sending a lady upstairs and the operator following, and I am not so sure that your correspondent's plan of going first is the correct one. The procedure, in my humble opinion, should depend upon the architectural construction of the place. Still, I know of some studios in which it is possible to get lost in a journey from the reception- or dressing room to the studio proper.—Yours faithfully,

M. P. P. A.

IRIS AND WATERHOUSE DIAPHRAGMS.

To the Editors.

Gentlemen,—With reference to the invention of the iris and Waterhouse diaphragms, attention may be called to statements made many years ago by Traill Taylor. Mr. Traill Taylor named Lake Price as being the real inventor of the "Waterhouse" diaphragm, Waterhouse making some improvements. It may also be mentioned that the latter worker was called "Dr." Waterhouse by Mr. Taylor.—Yours faithfully,

A. MANSFIELD.

THE 1923 P.P.A. CONGRESS.

To the Editors.

Gentlemen, I am pretty much in agreement with Mr. J. Speight, but think now that the matter has been brought prominently before photographers, it would be better for all who are interested in the subject to write to the Council and continue the discussion in the official "Record." The subject is hardly one that concerns amateurs or those photographers who refrain from joining the P.P.A., but it should concern the existing members very considerably. Country members must, of course, bear in mind that they alone could not run the P.P.A. without the London help, and the London men may equally bear in mind that though they can no doubt organise a successful exhibition of portraits without *much* assistance from country members of the P.P.A., yet without the country subscribers the Conference and the P.P.A. would soon cease to exist.

WILLIAM COLES.

18, Queens Road, Watford,
October 24.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

L. L.—The Williamson aerial camera is made by the Williamson Kinematograph Co., Hawthorn Road, Willesden, London, N.W.10.

E. H.—The firm for brass camera parts is Messrs. James Christie & Sons, Ltd., 246, West Street, Sheffield. For optical repairs, the Premier Optical Co., 63, Bolton Road, Stratford, London, E.15.

L. B.—We think you will be able to get what you want from Messrs. Garratt & Atkinson, Warwick Works, Ealing, London, W.5, who have a very large selection of stereos of decorative headings, etc., and can quickly get out a new design to any requirements.

H. T.—Your difficulty is due to the short depth of focus in your f/5.8 lens. For groups, such as the prints you send, we should advise you to stop down to f/11 at least. Focus sharply at full aperture upon a figure midway between the extremes, then stop down to f/11 before exposing.

H. C.—We should think the "mealiness" you complain of is due to scum on the surface of your developer. If the developer had become nearly exhausted a scum would form on the surface, and unless the print were moved about in the bath this would adhere to the surface, and give small, uneven markings.

W. U.—We suppose it is a half-tone impression on newsprint, in which case it will make a very poor lantern slide. About the best thing you can do is to make a copy on a very rapid plate, the spread of light in the emulsion of which does something towards removing the half-tone structure of the original.

E. D.—For such work as you require you should send the negatives to somebody who will take a personal interest in carrying out such "faking" himself, and is an expert in this line. We recommend for this purpose Mr. H. W. Bennett, 17, Ranelagh Gardens, Ilford, Essex, or Mr. John H. Gear, 8, Nottingham Terrace, Marylebone Road, London, N.W.1.

R. T. S.—The reflected-light vertical enlargers give a softer rendering, and do not show up scratches or retouching of the negatives. However, the exposures necessary are of longer duration than those with a lantern using a condenser. In the Aldis-Ensign vertical enlarger, however, a special condenser is used in which shorter exposure is combined with a measure of diffusion.

R. H.—Tri-colour filters are obtainable from Messrs. Kodak, Ltd. (Wratten Division), Kingsway, London, W.C.2, or Messrs. Sanger-Shepherd & Co., Ltd., 5-7, Gray's Inn Passage, High Holborn, London, W.C.1. The best book for your customer is "Science and Practice of Photography," by Chapman Jones. This is now out of print, but you could probably obtain a second-hand copy from Messrs. Foyle, 121-123, Charing Cross Road, London, W.C.2.

R. L.—There are numerous remedies for amidol and metol skin poisoning, some of which benefit some people and some, others. A formula which in our experience has been beneficial to many people is one which we publish in the "Almanac." There is no ready method of removing amidol stain from the skin. The best thing you can do is to use pumice stone, and, as a preventive, rinse the hands in water containing a little hydrochloric acid every time after handling the developer.

C. R.—There is no book which will enable a person to carry on studio work without personal instruction. The little manual, "The Portrait Studio," which we publish, gives a good deal of information on studio portraiture, and as regards the general principles of photography, about the best book is "The Science and Practice of Photography," by Chapman Jones, at present out of print, but no doubt obtainable from Messrs. Foyle, 121-123, Charing Cross Road, London, W.C.2.

H. A.—So far as we know, there is no firm now that makes photographs in cameo relief. This was a specialty years ago of the Taber Bas Relief Co., but we do not think they are now in existence. There is a French firm, M. Phidias, 368, Rue Saint-Honoré, Place Vendôme, Paris, who makes these relief photographs in colours, but at price of about £5 5s. apiece. For the white mounting boards we advise you to apply to Fordham & Co., Ltd., Victoria Works, Victoria Road, Walthamstow, London, E.17.

G. B.—We do not know of any other method which can be used than ordinary enlarging on bromide paper. Presumably only one enlargement is required from each original. If more than one is required it would perhaps be cheaper to make an enlarged negative on thin bromide paper, and make duplicates from that on ferro-prussiate or blue-print paper. You could easily have these blue prints made from your negatives by a firm such as B. J. Hall & Co., Chalfont House, Great Peter Street, Westminster, London, S.W.1.

G. W.—We do not quite understand your query, since "art" paper here is usually paper with a coating of mineral matter for a high gloss, and we do not suppose for a moment that is what you mean. We should say the purest rag paper, and one also which is of artistic surface suitable for mounts, is Whatman's drawing paper, made by Messrs. Joynson, St. Mary Cray, Kent. It is a regular article among dealers in artistic requisites, no doubt in your town as well as here. A firm here which would supply is Messrs. Reeves & Son, 4, Farringdon Avenue, London, E.C.4.

J. H.—We should suggest that you fit three 3,000 c.p. half-watt lamps on rising and falling fittings, suspended from above and near the wall on the right-hand side of your studio. The lamp nearest to the sitter should be about 10 ft. from the background and the other two as near to this as practicable. Another 3 000 c.p. lamp should be provided on a movable stand for use on the left-hand side of your camera, if necessary. This could be moved about the studio into any position required, either to increase the existing lighting or brighten the shadows. A lamp could also be provided hanging from above, as No. 4. This should be about 9 ft. from the ground, and encased in an opal bowl; 2,000 c.p. would be sufficient. The light from this could be reflected down from the top blinds, which would have to be of a white material. We have marked the position of the four lamps on your plan, and these should be hung in such a manner that each lamp could be placed near the floor or the ceiling as required. You will have to provide diffusing screens for all the lamps except No. 4, and these would be best if fitted to the lamp bodies. The General Electric Co., Magnet House, Kingsway, London, W.C.2, make a specialty of studio lighting, and would forward you their booklet giving prices and particulars of their various fittings upon application.

JOURNAL OF PHOTOGRAPHY.

No. 3261. Vol. LXIX. FRIDAY, NOVEMBER 3, 1922. Price Fourpence.

Contents.

SUMMARY.

Working instructions in the use of sulphuric acid as an accelerator of hypo-alum toning are given by "Thermit" in a note on page 665. Prints are passed first through a bath of 1 or 2 per cent. sulphuric acid, then through weak fresh hypo solution, and then into the alum-hypo toner.

In continuing his notes on accessories and backgrounds in the studio, Mr. J. Effel has much useful advice to give on the avoidance of artificial accessories and highly scenic backgrounds. (P. 663.)

In a leading article we endeavour to present in a popular form a short discussion of the effect of distance of camera and focal-length of lens, both in studio portraiture and in the photography of somewhat large and near objects, such as motor cars. (P. 662.)

Good use may be made of an exposure meter in estimating the strength of studio light when employing an arc or half-watt lamp as a supplement to daylight. (P. 661.)

It is expected that judgment will be given within the next day or so on the appeal of Messrs. Wykeham Studios, Ltd., against the decision of the High Court some months ago respecting power rates for electric current used in studio arc lamps. (P. 671.)

Several correspondents give their experience and advice on safe-lights for dark-room illumination when handling bromide paper. (P. 671.)

In enlarging scratched film negatives, much touching of the enlargements may be obviated by varnishing the films with a brush or by immersion. (P. 661.)

Both too slow and too rapid drying of negatives involve certain drawbacks. In a note on page 662 we refer to a medium speed method of drying which is useful at the present damp season for negatives which are required without loss of time.

At the Royal Photographic Society on Tuesday evening last Mr W. B. Appleton gave an interesting discourse on past and present methods of making photographic lenses. (P. 668.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

In a recent paper contributed to the "Club Photographer," Mr F. G. Tutton has given working details of the process used in the making of the three-colour transparencies to which a medal was awarded in the recent exhibition of the Royal Photographic Society. Mr. Tutton used chemical toning and dye-printing in combination. (P. 41.)

In a contributed article, Mr. R. M. Fanstone gives some hints on the making of Autochrome and Paget transparencies in small sizes. (P. 43.)

M. Eugène Muller records his experience in using desensitising by aurantia in the development of Autochrome plates. (P. 44.)

Full particulars have now been given in a patent specification of the before-lens optical device used by Professor Procoudine Gorsky for splitting up the light into three beams in his process of colour cinematography (P. 42.)

EX CATHEDRA.

Mixed Light in the Studio. On dull days it is sometimes advantageous to secure a little more brilliancy in the negative by employing supplementary illumination from a half-watt or arc-lamp. The chief difficulty in doing this is that of correctly estimating the value of the combined lights for the purpose of exposure. This we have found may be done by using an exposure meter, the simplest being as effective as the most complete, since all that has to be done is to match the tint by daylight alone, note the time, and then to get a second tint with the addition of the artificial light. The exposure will be, roughly, in direct proportion to the respective times. It is, of course, assumed that the correct exposure for daylight alone is known. If this be not the case the exposure may be calculated entirely by the aid of the meter used in the orthodox way. We have found with an ultra-rapid plate and an aperture of *f*/5·6 that for a half-length portrait about half a second per meter minute (full tint) gives ample exposure.

* * *

Scratched Films. In enlarging film negatives which have become scratched by carrying in the pocket without proper protection, a great improvement may be effected by coating both sides with varnish, which fills up the cracks and restores the general smoothness of the surface. It is, however, important to avoid the use of any varnish which contains alcohol or amyl acetate. Ordinary negative varnishes or any solution of celluloid will probably cause the film to buckle. Varnishes made with benzole or turpentine are free from this defect, as are also aqueous solutions of shellac made with ammonia or borax. It is possible to apply the varnish with a brush, but it is better to make it quite thin and to immerse the negative entirely. If a water varnish be used the negative may be printed from as soon as it is dry, but with other solvents a couple of days should elapse before the film is put in contact with either glass or paper.

* * *

Getting Business. There is a striking difference between the way the ordinary manufacturer or first-class retailer goes about finding customers and that adopted by most, but not all, photographers. The manufacturer relies upon direct attack; he uses his trade papers as a means of broadcasting knowledge of his goods, but he knows that unsupported this will only be partially effective. Therefore, he sends to his possible or prospective customers not only circulars but personal letters drawing their attention to certain lines, and still further backs these appeals by sending a personal representative to demonstrate and display his leading lines. Our readers are quite aware of these tactics, for are they not carried out by our leading plate, paper, and apparatus firms! Obviously, such lines cannot be followed when

dealing with private people, but the idea of the direct and the renewed appeal is worth considering. Why should not a photographer who wants the Christmas orders of certain good people in his neighbourhood begin at once to make it clear to them that he is not only willing but able to meet their requirements and to demonstrate it by specimens? The cost would not be great and the risk of giving offence less.

* * *

Drying Negatives. Although the effect of rapid drying upon the density of a negative was noted in the early days of gelatine emulsions, it has only been pointed out recently that the size of the silver grains is affected in a similar way. Most old photographers have long recognised that drying with spirit or formaline, followed by heat, not only increases the density of the image, but destroys the "bloom" which is characteristic of a good negative, the image assuming a somewhat harsh or "wiry" appearance; they were therefore chary of drying important negatives in this way. A middle course which may be followed when an hour or so can be allowed for drying, is to remove all surface moisture from the film with fluffless blotting-paper or a fine linen handkerchief, and to place the negative in a current of air which can be produced, when possible, with an electric fan, or, failing this, by raising a window-sash to the height of the negative and standing the negative rack in the draught which is generally produced.

FOCAL LENGTH AND PROPORTION.

In discussing the effect of the focal lengths of lenses upon the appearance of the images produced by them, it is probable that the word proportion will be more readily appreciated by most photographers than the nearly synonymous one, perspective. Perspective is to most people a matter of straight lines, planes and vanishing points, and the everyday photographer finds it difficult to associate these with the features and limbs of a sitter or the outlines of a piece of furniture.

As a rule, a person of ordinary intelligence, who is entirely ignorant of the laws of perspective, is quite capable of recognising any serious infraction of them. He realises that the drawing or photograph is "out of proportion," or, perhaps, even more vaguely says that it "does not look right." This perceptive power naturally varies greatly with different individuals, some being able to detect faults in pictures of unfamiliar objects, while others could only do so when the originals are well known to them.

The whole art of representing solid objects upon a plane surface is based upon the fact that any object of a given size subtends a narrower angle with the eye or the photographic lens as the distance between it and the eye or lens is increased. A familiar illustration of this is furnished by the action of the art student who gauges the various objects in his subject by holding up his pencil and sliding his thumb upon it, afterwards marking the dimension so obtained upon his paper. Here we have a triangle, the base of which is the uncovered part of the pencil, the apex is the eye of the artist, and the height the distance between these two. Let us assume the latter to be fifteen inches, and proceed to carry out the operation by photography instead of by hand. To do this in the simplest manner we require only a box measuring fifteen inches from back to front, having a pinhole in the front and a plate or sheet of bromide paper fixed inside the back, the pinhole occupying the position previously held by the artist's eye. Upon development, we shall find that the image thus obtained corresponds in all its dimensions with the artist's sketch, assuming, of course, that he has accurately followed his measurements. This brings us to the point, that it is the standpoint, or rather the distance between the lens and the principal object, which is the controlling factor in photographic perspective. The greater this distance the less the apparent discrepancy in size between two objects which are actually the same size but are at different distances from the camera. This may be well illustrated by photographing the corner of a building so that the sides are oblique to the lens. If an 18-inch lens be used, at a distance of 120 ft. upon a whole plate, the convergence of the horizontal lines will not be too sudden, but if it be rendered necessary, by the presence of other buildings, to use a 6-inch lens, the unpleasant wedge-shaped "wide angle" effect is immediately produced. The size of plate and focal length of the lens used make no difference in the result, since, if a certain building can only be taken from a certain near standpoint, the top and bottom of such building and the lens form a triangle, and to obtain the angle subtended by the lens a certain proportion between the longest side of the plate and the focal length of the lens must be maintained. In other words, a 4-inch lens upon a 5 x 4 plate will give from the same position exactly the same rendering as an 8-inch lens upon a 10 x 8 plate, except, of course, that the linear dimensions of the latter will be doubled.

It is often said that short-focus lenses, when used upon open landscape, "dwarf the distance," but this seems rather a confusion of terms. What really happens is that foreground objects have to be approached so closely that they appear too large in proportion to the known dimensions of more distant ones. If a small cottage, with a wooded height far behind it, be taken at a distance of 300 yards with a lens of normal angle, say, 40 degs., the cottage will appear insignificant, but in agreeable proportion to the distance. Upon approaching to 20 yards the cottage will be many times larger, but the distance will practically be represented upon the same scale. This effect is not produced upon the eye of a person in the same position since he unconsciously views the cottage and the mountain as separate entities, which cannot be done with a photograph. That this is a fact is proved by the practice of Turner and other great landscape painters, who did not hesitate to exaggerate the altitude of their mountains and cliffs when they deemed it necessary.

Coming to portraiture, these principles are equally applicable; the violent perspective is even more harmful and unfortunately less easy to detect. An instructive experiment is to take two large cabinet heads, with lenses of 6 and 18 inches respectively, so that the head is of equal height in each. The distance with the latter lens will, of course, be practically three times as great as that with the former, and the enormous difference in effect will be due to this only. Using a 6-inch lens for a 2½-inch head is, of course, an absurdity, but it must be remembered that the effects which are so evident exist in a lesser degree in portraits taken with an 8-inch lens, and in rapidly diminishing amount in other focal lengths, till the 18-inch is reached. It may be that the sitter is not rendered hideous, but there is a loss of likeness which cannot well be accounted for by any other hypothesis.

The conclusion to be drawn is that in all cases of outdoor work the longest possible focus should be employed. For motor cars and similar subjects even a telephoto lens is often useful, while for portraiture a distance of five feet between the sitter and the lens

should be the least. If larger heads than the lens in use will give at this distance are required, then enlarging should be resorted to or a larger lens obtained. As a rule, the front combination of a portrait lens used alone will give an image one and a half times as large as the complete lens will at the same distance, and thus the problem may often be solved in a very inexpensive way.

WITH A PORTRAITIST IN THE STUDIO.

[In the present paper, of the series of articles by Mr. J. Effel, which has been appearing in recent issues, the author talks of accessories and backgrounds, and, from instances in a wide experience, urges the abandonment of the many artificial accessories still to be seen in portrait studios. The next article of the series will deal with hands and feet and full-length portraits.]

IX. *(continued)* - ACCESSORIES AND BACKGROUNDS.

I am not a kill-joy or a spoil-sport, and I would always succumb to the wiles of the seaside tout and get a "while you wait" of myself seated on the moon or steering an aeroplane; I will admit that there is hardly a ghastly accessory in existence that I haven't used, but these facts have nothing to do with the artistic varieties. I would not take from the beach photographer his pasteboard motor or rowing boat, nor would I suggest that he would do better without these properties. I only ask you to fully realise what you are doing, and in what category your work ought to be classed. The seaside "mug-faker" is generally a very astute gentleman, and has no pretension to the title of artist; he talks about our profession as a "game," and refers to accessories and their uses as "fakes" and "stunts." I have nothing but goodwill for this brother photographer who is generally a very cute psychologist. I am addressing these articles, however, to young photographers in business in the ordinary way, and those who hope to make their living by supplying serious portraits to the public, not merely funnygraphs for holiday makers. The imitation Rolls-Royce could not deceive a blind man, and even the smallest knowledge of astronomy should tell us that man's place in the universe is not of the generous proportion he is accorded on the lap of the queen of night. As I have said, no sane person would take those things seriously, but I certainly feel that the city "portrait specialist" who shows in his case, *and quite seriously*, all those monstrosities I have been writing about in my last article, has no earthly reason to laugh at the itinerant.

If a man says to me "Yes, I know that seat is out of place with that background, but it was the first and only exposure I made of a very difficult child," or "My clients like to be 'took' with fine scenery," I quite understand him. A man may have to split artistic infinitives many times daily to earn his living, *but so long as he knows*, his soul may yet be saved. But if he is going on from day to day producing the same old goods, working the threadbare accessories and the more threadbare positions, and uninteresting lighting, *and has the audacity to think he is a live man*, I hope he may be persuaded to read my articles.

Whether the general scheme we are working for is to be simple, decorative, or elaborate, the figure of the sitter must be the first consideration, and must suggest the tone of the background, and indicate if an accessory is needed to help the composition. In my studio, I have not in use two chairs of the same height and design. Take the usual standing figure portrait and look at it critically. One hand is hanging loosely, and the other is placed on the back of a chair, a stone wall, a pillar or a table. We may have different pedestals, chairs and tables for use with children, but adults are all thought of as medium sized. Take away the bridge from under the sitter's hand, push in the latest posing device, ring down the new interior background, and yet you only succeed in changing externals which signify little. As the French would say, the more you change the pose, the more it is the same. No amount of thimble-rigging with furniture and scenery will make interesting the work of the operator who has very little knowledge of art anatomy, no appreciation of beautiful lines and curves in figure and clothing, *and who has never practised selection with a model, for ten minutes in his life.*

I must say honestly that it takes my breath away to hear some of the grousers in our business. I remember once advising a fairly intelligent assistant to practice posing and lighting in his spare time, and offered him the benefit of my guidance. "I came here to print bromides, and I don't want to be teached about art galleries and statues with lumps chipped out of them," was his delightful reply, "when my work's done of an evening, I want a game of billiards; no art classes for me."

I didn't get offended at this reception of my friendly overture, but I made an appointment with Tom, and gave him something to think about in the way of billiards. I finished up by giving him a hundred in three, and a thirty break, and a good hiding. Then we sat down for a drink and a chat. He was enthusiastic about my cuemanship, and wanted to know the secret. There was nothing to know except that where he had likely played more games than I, I had studied theory and sound break-making methods, and had put in a good deal of practising.

"But look here Tom," I protested, "there are hundreds of players who could knock my head off." Yes, he admitted that although useful as an amateur, I would be a poor antagonist for even a third class professional. That gave me my chance, and I pointed the moral in fine style. For years and years a budding billiard crack will spend hours daily in hard and patient practice, and yet the chances are less than one in a hundred that he will be able to earn a living as an exponent of the game, the proficiency of the top-notchers being so extraordinary that a very high standard of play is necessary for any player who aspires to appear in public as a performer. But surely portrait photography is as difficult as playing billiards? Yes, anyone can knock balls about and deceive himself that he plays billiards; and anyone can take a photograph on the "keep steady, one two three" principle, but for the professional standard, something better is needed. If a photographer is not content to take as much interest in his work as a marker does in billiards, he ought to go out of the business, before the public starve him out. Think of the men at the top of the tree in our business. They are as skilful with the camera as Newman or Inman with the cue, and the standard of work set for the young competitor in portrait making is a very high one. Fortunately, photography invariably maintains its fascination for its devotees through all the years of hard work. I would leave the business to-morrow if it wasn't that I get so much fun out of it. It would be a fitting end to my moralising if I told how Tom stuck in at his work, opened a studio, did beautiful pictures, made a fortune, and joined the P.P.A., but I am a truthful person. I am glad to say, however, that my old assistant is now doing well in a fruit shop of his own. Human beings are droll creatures!

Tom seems to me to work twice as hard now, but as he prefers pomegranates to photographs, well, good luck to him. I would say again to Grouser, if our business is played out, as you say, for goodness' sake play your miserable self into something that will suit you better.

Now, let me come back to the question of accessories and backgrounds. I am neither a Gordon Craig nor a futurist. I do not tell you to make a bonfire of your posing properties, for it would be unkind advice to a cripple to throw away his crutches until he was strong enough to walk. Yes, you may not like it, but artistically you *are* a cripple, and you make one of your client if you rely overmuch on accessories. In previous articles I have taken up a good deal of time with verbotens and defendus and homely dont's. Let the ambitious student extend the list. Take an ordinary kitchen chair, and a model; then, with no other accessories, save perhaps a flower or a letter, try very hard to get a big range of standing and sitting positions. Walk all round your sitter, and if you choose, expose midget plates. For most standing figures, have the chair out of the way; if the sitter is a lady, she will have so many personal things that will serve as real accessories, gloves, vanity bag, beads, fur stole, etc., which will occupy the hands in a perfectly natural and convincing way. At first you will be nervous, and will be inclined to look round for your crutches, but if you manage to stick it out, you will surprise yourself, and find that you have gained so much in strength that you are no longer a cripple.

Apart altogether from the canons of art, there is a factor that cannot be ignored, the consideration of fashion. A photographer must take a wide view of things, and apprehend the evolution of ideas concerning all the arts. Modernity and a refinement of criticism have had wonderful effects on literature and the drama. Evolution by no means signifies improvement, but merely change. Enough for us to understand that change. *All art is one.* Shakespeare would have to serve up his plays differently to-day. I can imagine a smart manager addressing the bard thus:—"This 'Merchant of Venice' is the goods all right, Shakey, my boy, but all this foolery between Launcelot Gobbo and his father is like the flowers that bloom in the spring. We'll have to cut that out, old bean, for our public won't stand for it as they did in your day." Sir Walter Scott might be told to cultivate précis writing, by a modern editor, and it is a sure thing that a young author who wrapped up his romance in a wealth of descriptive detail, would have difficulty in finding a publisher. The tendency of the age was expressed by Ibsen to Björnsen (not in my hearing), "Less of the glaciers, of the thunderstorms, of the moods of nature, and more and more of the heart and soul of man."

Photography must fall into line. Beautiful as they are, Birket Foster water colours, with their wealth of detail are out of date. Victor Hugo's day is past, the direct method of De Maupassant, who never used a superfluous accessory or background, has conquered. As Phil May rubbed out from his drawing every line that did not materially contribute to the story he was illustrating, so the portrait student should work.

The white background was hard on those who formerly favoured the elaborate, a portrait with nothing else but the sitter either possessed some intrinsic merit or was shockingly bad. It was a difficult style to work for those who, like myself, are fond of losing awkwardness of outline, but it was a splendid training to take all sitters for a time with the same ground. I remember about the end of the war period, talking with a brother professional (Mr. Charles Haig, of Belfast), who made a great hit with sketch portraits. He was unrolling a dark background which had been out of use for some time, and he remarked that he must have taken 20,000 sitters in succession with the same white background! And yet there was wonderful variety in the work both in lighting and posing. I think that should be conclusive evidence that a big business can be done with the minimum of accessories and backgrounds. It appears that the day of the sketch style has now gone, but a plain white ground is almost sure to be frequently required, particularly for costume and general theatrical work. I sometimes wonder if photographers like paying out money for reflectors, screens and the like, which they could easily make themselves. The white background is a case in point. There is scarcely a studio which has not one end that can be treated with distemper, and make a far more satisfactory background than a canvas screen. Children may lean against it, tricky effects with shadows can be worked, and while there is never any fear of the slightest wrinkle, dirty marks can be instantly touched up. A splendid "continuous" effect can be made by white painted linoleum, fixing the latter to the wall about a foot from the ground and shaping it to curve to the floor. If the edge of the linoleum is neatly bevelled and joined, before the final coat of white, you will have the most serviceable white continuous background extant. It may be necessary to point out that a large white expanse should always be covered when working with a darker screen, otherwise there will be difficulties with the lighting.

So much has been written about sketch work that I do not wish to risk mere repetition. It is pretty generally known that the tone of a background is subject to very great modifications, by placing it near the sitter or far away, angling it slightly, or allowing independent light to illuminate its surface. Light grounds which approximate to flesh tones sometimes give quite unforeseen results, particularly with figures turned towards the light. Frequently the face and light clothing "run in" to the background. In a previous article I advocated a slight exaggeration of contrast in lighting to make up for the loss of colour. Under exposure will heighten contrast, but by far the best way for the busy worker is to have standardised methods of working which will give the minimum of trouble. Avoid the picture with face or figure turned towards the light when the background is of the "lighter than the subject" order. Light blouses, dresses, and babies' robes can stand all the shadow you can get into them. I am all the time thinking of tank development and straight printing. Doubtless good "high key" effects can be got looking to the light, but it is asking for trouble, and putting an undue strain on the busy printer. It is almost an unbreakable rule with me to turn all white garments away from the light, and to lower their tone as much as I can. A little dark screen about four feet high is useful in this connection.

Many up-to-date photographers have now completely abandoned the scenic background. That is a healthy sign. The alleged "interior" with the marble steps (well wrinkled) growing out of the drawing room carpet and vanishing at a stained glass window while palm trees sprout from the fireplace on the right, and the book-case is suspended in space at the other side, deserves a well-earned rest. In my boyhood I served a good apprenticeship to the scenic school. The boss was a maniac on the subject, and invented a complicated bit of mechanism to hold eight backgrounds, the one desired being supposed to come into position in response to the touch of a lever. That I understood was the theory, but in practice, the working resembled the antics of the folding bed which turned itself into a pair of steps in the middle of the night and refused to be coaxed back into any other combination except a washing machine. There was a numbered list with titles of the backgrounds, but that was only camouflage, for as sure as you decided for a "dark interior" the snow scene would unfold itself. True, you might say this was easy, and that it went by opposites, but there was a more subtle perversity behind this Frankenstein monster. If a garden scene happened along, and you were resigned to bear the ills, etc. (Shakespeare), and placed your sitter to your satisfaction, wild breakers would suddenly appear in the sky, descend leisurely on the horizon, gather momentum by contact with the sun-dial, and flood the garden with surf, sand, wrinkled

rocks and flotsam and jetsam. Frequently a stout roller made a striking appearance—on the head of the unfortunate posee. Inventors are optimists, and these disturbing incidents did not daunt the boss. A sitting was never completed in my memory without the other apprentice and I standing on chairs holding a background in position, and preventing the other seven from acting in concert against us.

Years later, when starting in a new job, I saw one of those cursed contrivances in the studio. I protested at once, but the proprietor sought to mollify me by the assurance that only one of the rollers worked, and that it was therefore quite harmless. He said he only kept it for appearance, but that was my greatest objection to it. I put my foot down, and refused to be put off by the suggestion that he would advertise the clumsy thing in the "B.J." Either the octagon—revolving—automatic—time-saving background stand left the studio at once or I did. I won my point, and started work with a light heart.

The remark that accessories should be regarded as suitable in conjunction with certain backgrounds ought to be tautological. Still, there are many accessories which are always used in what is thought to be the correct relation. I have known a piano with a forest, but never a deck chair in a drawing-room. The seashore is its proper place, suggesting that the bitter experience of being bilked out of twopence on his annual holiday has made a lasting impression on the photographer. I am a land lubber, and I think barrels and a coil of rope are nautical, but all the same I would rather not try those on a sailor. Jack sees plenty of the real sea, and much prefers to be taken seated in the parlour. Think for a moment, you would not dare to photograph a gentleman in an imitation motor, and yet you would lightheartedly take the battle-scarred soldier against paper tents, and think the illusion good!

Scenery has been superseded by simulation. I think the alleged panelling deceives as little as distemper or flatted oil. Three-ply board is useful, but with bits of egg box strapped across it at intervals of eighteen inches and stained with Condy's Fluid does not suggest opulence. I find it difficult to get away from the painted ground because in the best of them there is that fine distribution of light and dark masses, the use of which is as old as the art of Leonardo da Vinci. To me the great drawback with the plain wall type of background is the absence of relief. With the plain white ground, a little shading can be worked in on the print and the dead black ground is subject to considerable modification in the negative with a retoucher of average skill. A picture, flowers, or light piece of furniture, if carefully placed, will often afford that little bit of contrast needed to relieve an otherwise too plain scheme. Curtains are very amenable, and an odd half-hour can well be spent in arranging folds and studying effects. Why anyone outside of a lunatic asylum would order a painted canvas of a curtain, when the real thing was to be had much cheaper, is entirely beyond me.

Accessories then are aids to photographing our sitters, not merely objects with which they are photographed, and backgrounds should serve in an unobtrusive manner the purpose of throwing into relief the face or figure, and in some instances "losing" the shape of the sitter. I will deal more fully with this function of the background when treating full length figures.

A very good tip was given in this journal some time ago about the choice of studio furniture. It was suggested that the prospective purchaser should experiment a little with a lady in one or two poses with the chair or couch. It will be found that many pretty bits of furniture are quite unsuitable for general use, owing to their height, the style of the arms, or the lean of the back. That is why I always have alternative seats slightly different. Nothing looks more awkward in a sitting pose than an arm pushed up to hang on a projecting part or table. Comfort is not necessarily grace, but discomfort can never have pictorial merit.

The serious photographer must eschew the dear and nasty as well as the cheap and shoddy in accessories. Some chairs are good with certain subjects and settings only, and some are good with none. "Paper mashy" and all imitations must go. The white seat is my bête noire. The tendency of the age is towards simplicity and away from the ornate. I shall paraphrase the old Norwegian master and say:—

"Less and less of the pillar, the painted screen, and the fancy furniture, and more and more of the face and figure, and the character of the sitter."

J. Eftel.

SOME MODIFICATIONS IN THE ACCELERATED HYPO-ALUM TONING.

That the usual way of "boiling prints till they turn brown" has certain objections will be admitted by most of those who have stood over the hypo-alum bath for an hour or two on end, and early this year I described a method I had devised to improve the hypo-alum process. This was published in two short articles ("B.J.," 1922, February 10, p. 80, and March 3, p. 126), and since then I have tried out the system further in business. Constant practice with a process is bound to discover any failings, and should lead to practical improvement, and this has been the case with accelerated hypo-alum.

Originally, I transferred prints from the fixing bath (plain hypo) to a bath of 8 per cent. sulphuric acid. Sometimes I used stronger acid than this. From the acid I put the prints into a warm hypo-alum bath, but seldom bothered to turn them. Sometimes I left them in warm water, where they eventually toned without the help of hypo-alum, but I could never say what time they would be done. The warm hypo-alum bath was well worth while.

I had found everything satisfactory for some time, when I suddenly discovered that there was a possibility of staining through allowing used hypo to remain in the prints when immersed in acid. Silver thiosulphate, decomposed by the acid, one day caused a number of immovable yellow stains in the whites of a batch of prints. And once or twice I had cases of bleaching. Certain slight alterations in the *modus operandi* put matters right, and though the process—on paper—now seems more elaborate, it is safer and more definite and certainly preferable to the old-fashioned way of "boiling, etc., etc."

Prints fixed in plain hypo are washed for five minutes. If acid hardener is used, a longer wash may be necessary. From this wash, prints are transferred to a 1 or 2 per cent. bath of sulphuric acid. Stronger acid can be used, but I have found no advantage in increasing the strength. Dry prints put into the acid remain until they are limp. Wet ones need two minutes, and if there is a quantity they need turning over. The next step is to drain them for a moment and immerse in weak but fresh hypo solution, which must not have any traces of sulphurous acid in it. That is, it must be free from sulphite, metabisulphite, or acid hardening mixtures. A strength of 1 or 2 in 20 will do. Here the prints are turned about till the solution turns very cloudy, when they are ready for the toner. The action in the weak hypo takes a minute or two. If warm toner is not available, a good rinse, followed by immersion in warm water will finish the process, but an hour or two may be necessary. In no case should turning over be necessary after the cloudy action.

It may be well to note that forced prints, and prints on certain makes of paper—distinguished by their ability of giving dead cold blacks in spite of adverse treatment—do not readily tone brown by this (or any other) process. Generous exposure and smart development in moderately restrained developer are great helps to expeditious toning.

Thermit.

£2,000 Found in a Camera.—Mr. Henri Bourdin, the "Daily Chronicle's" special correspondent, telegraphed the following item of news from Paris: Two small bags, each containing £1,000 in gold and notes, were found by a grocer named Binjon, of Fontainebleau, in an old camera which he had bought at an auction sale. It had belonged to an aged priest, and the grocer has handed the money to the dead man's heirs.

FORTHCOMING EXHIBITIONS.

November 4 to 11.—Bournemouth Camera Club. Particulars from the Hon. Secretary, 88, Old Christchurch Road, Bournemouth.

December 9 to 31.—Rochdale Amateur Photographic Society. Particulars from the Hon. Secretary, W. Lord, 10, Derwent Street, Rochdale.

1923.

February 5 to March 3. Northern Photographic Exhibition, City Art Gallery, Manchester. Latest date for entries, January 12. Particulars from the Hon. Exhibition Secretary, Walter Johnson, 30, Hartington Road, Chorlton-cum-Hardy, Manchester.

March 1 to 8.—Birmingham Photographic Society. Latest date for entries, February 15. Particulars from the Hon. Secretary, J. E. Breeze, 178, Broad Street, Birmingham.

March 2 to 31.—Pittsburgh Salon of Photography. Latest date, February 5. Secretary, Charles K. Archer, 1,412, Carnegie Building, Pittsburgh, Pa., U.S.A.

March 13 to 16.—Exeter and West of England Photographic Exhibition. Particulars from the Hon. Secretary, Frederic G. Tutton, 9, Union Road, Pennsylvania, Exeter.

March 15 to 24.—Photographic Fair, Holland Park Hall. Secretary, Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications October 16 to 21 :—

FILM HOLDERS.—No. 28,577. Holders for photographic film. C. F. Abbott and Kodak, Ltd.

PRINTING FRAMES.—No. 28,017. Method of manufacturing photograph printing frames. P. G. Henry.

PROJECTION APPARATUS.—No. 28,181. Micro projection apparatus. F. N. Davidson.

FERRO-PRUSSIATE PAPERS.—No. 28,430. Production of sensitive ferric film photo papers or bearers. H. L. Shawcross.

PHOTOGRAPHIC SURVEYING.—No. 28,507. Photographic surveying. J. W. Gordon.

AUTOMATIC PROJECTION.—No. 28,293. Automatic machine for projection of a number of photographic slides, etc. I. O. Bullock.

CINEMATOGRAPHY.—No. 28,555. Cinematograph films. E. T. Perken.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

PRISM LENS SYSTEM, FOR THREE-COLOUR CAMERAS.—No. 185161. (April 30, 1921.) This invention consists of an arrangement of three prisms, mounted in such a manner that the incident ray, striking the first prism face, is split up into three separate images before entering the lens system. A series of rhomboidal prisms are cemented together, to form one combination prism, which is then mounted in front of three lenses. The coplanar faces of the prisms are partially silvered or rendered partially reflective so that each prism face reflects separate image rays. These are then passed through three lenses on to the sensitive film or plate surface. As the distance traversed by the image forming rays varies in each instance, the lenses must be mounted in such a manner that each will bring the rays to a sharp focus in the general focal plane, when only one sensitive surface is used. The lenses have their focal lengths corrected for use with light-rays of a definite wave-length, corresponding to a region of the spectrum occupied by the rays passed by the colour-filters used.

A variation of the system allows three films or plates being used, the lenses being then placed at equal distances from the prism face. In the case of a cinematograph camera, the film gates are placed in parallel planes to each other, but at different distances from the central axis of the combination prisms. Various methods are provided for correcting distortions of the images. One method is to equalise the path of the light-rays, in the media through which the rays pass, while another for use when ordinary photographic lenses are used, is to place a sphere parallel lens or lenses, in front of the system of prisms or each objective. Serge Michael de Procoudine Gorsky, The Dell, Croft Road, Sutton, Surrey. (Particulars of the construction of the system are given on another page, in the "Colour Photography" Supplement.)

New Books.

LENSES IN USE.—No. 187 of the "Photo-Miniature" is a practical guide to the choice and use of lenses, for different branches of photographic work. Some workers do not realise the importance of the lens, or its possibilities and limitations, imagining that one type of lens should be capable of dealing with all classes of subject. That the expert photographer is able to turn out good work even with indifferent tools cannot be denied, but it is readily understood that, given the very best of suitable materials, he would be able to do even better. But with the finest anastigmat some photographers would fail to produce good work, because their knowledge of the instrument they are using is scanty and insufficient. It is with the idea of educating the photographer to the possibilities of his lens, that the present volume is issued, and a careful study of its pages will do much to improve the worker's knowledge, and through that, his work. Lenses of all types are considered very fully, and their possibilities and limitations explained. Portraiture in the studio demands certain qualities in the lens, which qualities are not always found in the modern anastigmat, but the author advises the use of the modern portrait anastigmat, as he considers it a great improvement upon the Petzval type of lens. Soft-focus lenses are not dealt with in this volume, their qualities being explained in No. 184 of the series. To the worker who is endeavouring to get the best out of his apparatus, we commend the present volume for careful study. The "Photo-Miniature" series of booklets are obtainable from Messrs. Tennant & Ward, 103, Park Avenue, New York, price fifty cents, or Messrs. Houghtons', Ltd., 88, 89, High Holborn, London, W.C., price 1s. 8d.

LA TECHNIQUE CINEMATOGRAPHIQUE.—Perhaps the most complete treatise ever published upon the details of the manufacture and display of cinematographic pictures is this volume, in the French language, bearing the above title, from the pen of M. Leopold Lobel. Throughout the 354 pages of profusely illustrated text M. Lobel gives his readers the history of cinematography and the apparatus involved, together with its very latest applications. The mechanism of all the most popular types of projector is most fully explained, and many excellent illustrations and diagrams are given. The illuminant is carefully discussed, and various types of electric arc lamps and machinery for generating the necessary current are described.

The oxy-acetylene system of illumination, which is extremely useful under conditions where electricity is not available, is very fully described, methods of manufacturing and purifying the gases being given. The arrangement and setting of the studio claims a chapter to itself, while the methods of artificially illuminating the studio are very fully described. Many types of cameras are discussed and their advantages explained, while the great variety of camera stands, with their numerous and intricate adjustments, are given very full attention. The chapters upon development and printing of both the negative and positive film are ably written, and should prove of great interest to photographers who cater for this class of work.

A chapter deals with the toning of the positive film, and formulæ are given for both chemical and dye toning. The book is full of good advice for the production of the cinematograph picture, and will commend itself to all workers in this direction. The volume is obtainable from the Librairie Dunod, 47-49, Quai des Grands-Augustines, Paris (VIe), price 32 fr.

PHOTOGRAPHS OF THE BANK OF ENGLAND.—A correspondent writes to say that the work of heightening the Bank of England is to be commenced this month, and that photographers who wish to secure a last negative of this world-famous corner of London should lose no time in securing an exposure.

New Materials.

Gevaert Ortho-Sensima Plate. Made by Gevaert Ltd., 115 Walmer Road, North Kensington, London, W.10.

PRODUCED particularly for use in the artificial light studio, this new plate may be confidently recommended as a high-speed negative medium, sufficiently colour corrected to allow of short exposures being given to this means of illumination. The speed of the plate is declared as genuine 500 H. & D., and it is certainly a very high speed indeed. The plates which Messrs. Gevaert, Ltd., have sent us for testing, have been exposed upon a variety of subjects, under varying conditions of lighting, and in every instance, the negatives obtained have been of extremely high quality. In one case, where an exposure five times that indicated by the prevailing conditions was given, a negative, perfect in gradation, and with full detail in both shadow and high light, was obtained, simply by diluting the developer with an equal volume of water. Another plate exposed upon a portrait lighted by five grains of flash-powder gave a perfect negative fully exposed, thus proving the great latitude possessed by these plates.

A notable feature of the Ortho-Sensima negative is its particularly fine grain, which is similar in appearance to that produced in negatives upon very slow plates. Yet there is no doubt about the high-speed of the plate. Exposure in the studio using half watt lamps totalling only 6,000 candle-power, and with a lens working at *f*/6, were reduced, in the case of bust portraits, to one second, and fully exposed negatives obtained. Another notable feature is the great immunity of the plates from halation. An exposure was made to a window admitting a full amount of daylight, for fifteen minutes at *f*/11 at mid-day during the past week and a negative obtained, which was absolutely free from halation. The plates, exposed under the conditions mentioned above, were in each instance developed in the pyro-soda developer recommended by the makers, but diluted with an equal volume of water. This dilution would not be necessary, however, in the case of a normal exposure.

As a plate for general use in the studio and also for the press worker, when light is bad or of a yellowish nature, the Gevaert Ortho-Sensima may be strongly recommended, while for at-home portraiture using the ordinary room lighting, or flash powder it is of great value.

POSTCARDS FOR CHRISTMAS.—Messrs. Kodak, Ltd., are supplying professional photographers with a very charming set of Christmas postcard designs. Bromide cards are printed on the front, with suitable greetings and illustrated with really good black-and white Christmas drawings.

PASSE-PARTOUT BINDING PADS.—The chief difficulty in the making of a real and attractive passe-partout frame has always been experienced in getting narrow edges of binding upon the glass, and all of equal width. This difficulty may now be overcome by the use of the binding placed upon the market by Messrs. W. Butcher & Sons, Ltd., Camera House, Farringdon Avenue,

London, E.C.4. This binding has a carefully ruled impression along its entire length, 3 16th inch from one edge. This gives the correct proportions for the fold, and will therefore ensure each bound edge of the frame being of equal width.

The binding is made up in three lengths, viz., 8½, 10 and 12½ inches, and is supplied in pads perfectly flat and ready for use. The larger illustration shows a complete pad, and the smaller, a strip detached and folded. The binding is made in five colours, black, brown, oak, green, and havannah, each of distinctive surface texture. Three pads of strips, one of each length, are supplied in a neat card box. The price per box which includes directions for using the strips, is 1s. 6d.

CHRISTMAS CARD MOUNTS.—Messrs. John J. Griffin & Sons, Ltd., Kemble Street, Kingsway, London, W.C.2, send us a sample set of the Christmas mounts they are offering this year. The mounts are all of the up-to-date, double and triple folder types, with tasteful designs and mottoes embossed on the front cover. The mount illustrated is No. 102, which is supplied in grey, brown and white, the holly and seal design being in colours.

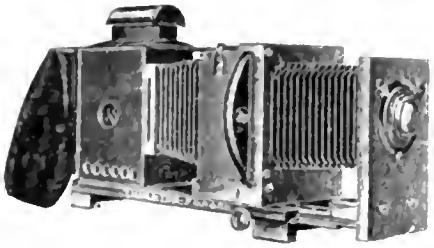
These mounts are cut from strong, well-made board and are extremely well finished. The whole series, which includes thirteen varieties, are, with one exception, intended for postcards, and either oblong or oval openings are provided. The exception is No. 269, which is intended for sketch portraits, and is so embossed. A particularly distinctive mount is No. 249, which has a brown embossed seal upon the front cover with the words "Best Wishes" inscribed in white. A gilt deckle-edge to the cover completes the

design. Sample sets of these mounts, comprising the whole range, are supplied upon application to Messrs. Griffin for the sum of 2*s*., post paid. It is hardly necessary to mention that orders and inquiries should be sent in as early as possible, to prevent disappointment as the supply is limited.

New Apparatus.

The Imperial Enlarging Lantern. Made by the Thornton-Pickard Manufacturing Co., Ltd., Altrincham.

A NEW model of enlarging lantern, to which the name of "Imperial" is given by the Thornton-Pickard Co., is one which it has been possible to place upon the market at a considerably lower price than has been charged during the last few years for this description of apparatus. As shown in the drawing, the enlarger



is externally of the customary condenser pattern, comprising a lamp house, pair of condensers, negative stage and bellows extension of the lens front. In certain details, however, the model represents certain new features. For example, a narrow stage is provided at the front of the lamp house for insertion of a sheet of ground glass, which is supplied mounted in a wooden holder for this purpose. The makers have also discarded the time-honoured system of mounting the condenser glasses in circular brass cells; instead, they provide a wooden box fitted with grooves into which the two condenser glasses loosely slide, one at the rear and the

other at the front of the box. The box is provided with a detachable and light tight lid, so that the glasses may be most easily and quickly removed for cleaning. The construction of the box, moreover, allows of satisfactory ventilation. A simple pattern of negative stage is provided, consisting of a stout frame which is held in alignment by a spring board and can be moved by hand for raising or lowering the negative in the stage and also for giving it a certain degree of angular movement in the plane parallel to the surface of the condenser. A particularly good feature of the enlarger is the ample extension provided for the protection lens—namely 15 inches in the quarter-plate size. This allows of reduction being done with the enlarger, and thus provides a convenient method of making lantern-slides from quarter-plate negatives, when the whole subject is to be included in the lantern transparency. The lamp house is also movable for adjustment of the distance of the light from the condenser.

The enlarger is made in four sizes, fitted with condensers of 5½, 6½, 7 and 8½ inches diameter, designed to take quarter-plate, 9 by 12 cm., 5 by 4 (and postcard), and half-plate negatives, respectively. Without a lens the corresponding prices are :— £5 5s., £6 10s., £7 17s. 6d. and £8 17s. 6d. The enlargers are supplied with a portrait lens, or with an Aldis, Cooke, or Beck objective, the prices in the case of outfits which comprise a lens including also an orange cap for the latter.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, NOVEMBER 6.

Birmingham Photo. Art Club.—"Flashlight Photography." A. Dordan Pyke.
Bradford P.S.—"A Tour in Italy." G. Halford.

Richmond Camera Club.—"Development." W. H. Withey.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held on Friday, October 27, Mr. W. L. F. Wastell in the chair. Dr. G. H. Rodman delivered a lecture entitled "Familiar Flowers in Monochrome," illustrated by many excellent slides.

Dr. Rodman said he had to apologise for some of his slides, if the masking did not follow the present day idea, as many of the slides were made 20 to 25 years ago. After showing a number of slides of well-known flowers, Dr. Rodman spoke of the difficulties experienced in photographing orchids in the hot-house. He described this branch of flower photography as the most sporty of all. To enter a hot-house with a temperature of 120 degrees was to obtain much condensation of moisture upon one's lens. But this was not all; the Turkish bath effect given by even a short sojourn under the focussing cloth called forth much unparliamentary language. A slide which was well received, and one which Dr. Rodman said the ladies knew well, was that of the parasitic plant viscum album, commonly known as mistletoe. The arbutus unedo, or strawberry tree, was another interesting subject. Its name was derived from unum edo (I eat one), which Dr. Rodman said was quite correct, one being quite enough on account of the objectionable taste. The appearance of one of the saxifrages upon the screen must have delighted the chairman, who had previously said this was his line of defence when asked to name a flower.

Dr. Rodman, in concluding his lecture, which must have delighted the flower lovers and botanists in the audience, said that much interesting work was to be done in the photography of flowers, either *in situ* or in the studio.

A vote of thanks was proposed by Mr. Wastell, who said he found his botanical knowledge was better than he imagined, as he (the chairman) knew the name of every flower shown on the screen before Dr. Rodman mentioned it. Dr. Rodman, in reply, said that the audience should also thank the lanternist, Mr. Goldsmith, who performed his duties excellently throughout the lecture season.

Meeting held Tuesday, October 31, the President, Mr. W. L. F. Wastell, in the chair.

Mr. W. B. Appleton, of Messrs. Taylor, Taylor & Hobson, Ltd., delivered a lecture entitled "Past and Present Methods of Making Photographic Lenses." Speaking of the methods of lens making, Mr. Appleton said that at the time of his apprenticeship at Leicester lenses were made by methods very different from those in use at the present time; the work in the old days was in no way as congenial as it is under the present conditions, using highly scientific machinery. Before the advent of mechanical lens making it was necessary to obtain the optical glass in sizes as near as possible to the lenses which were to be made, and these pieces of glass were roughly cut into discs by means of a pair of scissors-like instruments called shanks. When a number of discs had been cut these were cemented together to form a roll, and were then shaped on the outer edges until the roll was perfectly cylindrical. The glasses were then separated and individually ground upon each face to the requisite curvature. The tools used were of a very primitive nature. One instrument for shaping the glass, shown by the lecturer, was merely an old saw file hardened and pointed. The next process was to affix a number of ground lenses to a metal holder, by the aid of pitch, and these were ground by hand, using a metal shell lined with pitch or wax. Rouge and water was continuously poured over the surface of the glasses which were revolving rapidly, while the operator continued to move the shell in various directions until a perfect polish resulted. Mr. Appleton had on exhibition a specimen of moulded optical glass in the form of a lens, but he said this method of manufacture was not suitable for high-class lenses, and was used chiefly in the form of condensers for lantern work. Coming to the modern method of lens making, Mr. Appleton said that it was now possible to obtain optical glass in fairly large slabs, which could be cut to the desired size by simple means. Before attempting to cut the glass, however, it was carefully polished on each side, so that the optician could examine carefully the actual construction of the material. Faults such as striæ and large bubbles could then be detected and the glass cut to avoid them. Special qualities were required in optical glass, qualities which were not found in the usual plate-glass used for windows, etc. The refracting and dispersing powers of optical glass had to be carefully adjusted, and in these respects optical glass differed entirely

from the usual type of glass used in other manufactures. Bubbles in the glass, which sometimes are found in high-class lenses, were usually very small and had no deleterious effect upon the image produced. In fact, the appearance of small bubbles was to some extent a hall-mark of quality, inasmuch as they proved that the glass had not been overheated before annealing. The cutting of the block of glass was then explained, and the soft-iron disc with small saw-like teeth filled with diamond dust, used in this operation, was exhibited. The glass was then subjected to the work of the disc cutter. This tool, also of soft iron with teeth filled with diamond dust, was of hollow cylindrical shape and was affixed to a drill-like machine which drove the disc through the glass. A method adopted in the manufacture of the cheaper type of lens was explained by Mr. Appleton, who showed a special patented shape block of glass, which allowed of the maximum number of discs being cut from it, with the minimum of waste. The disc was then attached to an ingenious tool of lathe-like construction, and the surface made either concave or convex by means of grinding with special wheels of carborundum. The method of obtaining convex curves of greater or less curvature was ingenious to a degree and eminently demonstrated the great advance which has been made in this direction. The machine for polishing lenses was then explained, and by means of lantern slides the lecturer pointed out the improvement of this upon the old method, while the moistening of the glass was carried out under more hygienic conditions. To test the actual curvature of the surface gauges as used in the older methods were not sufficiently accurate, and at the present time a proof glass was made of corresponding yet opposite curvature, and the lens being manufactured was adjusted to this. The well-known method of obtaining interference colours (Newton's rings) was used for ascertaining the accuracy of the work. A specimen shown was stated to have 1/50,000th of an inch air gap between the surfaces. A very graphic demonstration of the theory of interference was given by Mr. Appleton by the aid of a lantern polariscope, the colour bands in two lenses and also in a soap bubble being shown upon the screen. After polishing, the lenses were accurately centred, and then were ready for mounting in the usual brasswork.

Speaking of metal work, Mr. Appleton said that tubes, flanges and screws for lenses were made to limit gauges, which allowed no more than 1/1,000th of an inch error.

In conclusion, the lecturer put several slides upon the screen showing the different types of machinery used, and also an interesting slide demonstrating the method of centring the lens before grinding the edges. Several Cooke lenses were exhibited, including the "Primoplane" and "Aviar," two well-known types, and also the special cinematograph lens of an aperture of *f*/3.1. Some interesting photographs were upon view which were taken during the first Arctic Expedition. The Cooke lenses were found specially suitable for the extremely cold climate, there being no cement between the glasses.

On the proposition of Mr. W. B. Ferguson, a very hearty vote of thanks was accorded to Mr. Appleton for a lecture as lucid as it was interesting.

CROYDON CAMERA CLUB.

The august Council having deliberated regardless of the effluxion of time prior to last week's meeting, loud cries of "Red-time" greeted the President on his rising to usher in Mr. N. Moody on "Mounting and Finishing Prints." It was his first appearance as a demonstrator, and in quiet, unpretending fashion he made good.

Dry-mounting with an electric flat-iron formed the main theme, and those who might find the subject too dry, he remarked, would discover an obvious antidote close at hand. No difficulty had been experienced in mounting prints up to 15 x 12 on the thinnest of mounts, but adhesive tissues which answered well with machines did not necessarily work kindly with a flat-iron. He had found the "Victor" tissue to be the best for the latter. He had also found that a flat-iron worked better than some of the small mounting machines on the market designed for the use of amateurs.

The second part of the demonstration dealt with working up and spotting bromide prints. The lecturer once knew a teacher at an Art School who never could acquire the art of spotting without a full record of the operation, and another young lady, an apprentice to a photographer, at the end of six months had only learnt how to nibble the end of the brush. A good brush, and one not too small was essential. Spotting brushes sold by photographic dealers were to be avoided at all costs. The size known as "small goose," set in quill, as supplied by artist colourmen, answered admirably, provided the point was right. Pleading faintness, a glass of cold water should be asked for, and the brush tested by dipping it into the water and then bringing the hairs sharply over the edge of the glass. If they sprang back to a point (the point consisting of all the hairs, not a few) then it might be regarded as eligible for a second test, which consisted of spraying the hairs over the thumbnail and again examining the point. On an average, ten of such tests would discover one suitable brush. He made no mention of the attitude likely to be adopted by the assistant whilst this patient research work was being conducted.

The demonstration concluded with an exposition on colouring photographs in pastels and oil colours, and many striking and cheerful studies were passed round, of a kind bound to enliven the dullest apartment. The great advantage of oil colours, he said, was that they could be almost entirely rubbed off again, a gratifying feature not taken advantage of by the lecturer in the pictures shown.

In the discussion nothing definite could be extracted from Mr. Moody on how to gauge the right degree of heat of the flat-iron. "One soon learns," he remarked. Mr. Jobling said if half-a-second's dwell on the skin of the hand was possible, the temperature was about right. He had often employed a billiard iron with satisfaction; its rounded corners prevented development of lines. The President (Mr. John Keane) said he had recently spoilt one of his best bromoils by attempting to dry-mount it before it was quite dry. Many expressed a strong wish that he would repeat this procedure on every available occasion. A hearty vote of thanks was accorded Mr. Moody for a practical and very useful demonstration.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

An adjourned meeting of Council was held at 48, Baker Street (the president's studios), on October 19. Present:—Messrs. Marcus Adams, Angus Basil, Gordon Chase, Alexander Corbett, C. F. Dickinson, W. E. Gray, George Hana, W. H. O. Wedlake, and the secretary (Mr. Alfred Ellis). Mr. Corbett (president) in the chair.

The secretary reported the receipt of various letters on co-operative advertising, and, on Mr. Wedlake's proposition, these were referred to the appropriate sub-committee.

A letter was read from a member asking for advice as to payment in the case of some local views taken for a large firm for postcard reproduction. It was decided to put in the "Record" a warning to members that in taking photographs of local events, etc., for outside people they should get a proper understanding beforehand as to what it was proposed to do with the pictures and to what extent reproduction rights were claimed.

A member wrote asking whether a contract which he had made with a firm of advertising contractors could be amended. The contract was for a show case at a station some miles from his studios, and, the advertisement proving unremunerative, he desired to have it shifted to a more promising locality. He was, however, under a five years' contract to have it at that station, and his applications had been refused. The secretary wrote to the contractors and got the matter adjusted satisfactorily.

A letter was read raising the question whether a photographer was liable to pay unemployment insurance in the case of a woman cleaner of a studio who also did domestic work in the house. Beyond cleaning the studio, the woman in this case was not employed in any part of the photographic business. She was paid for by her employer under the unemployment scheme until March, 1922, when, seeing a statement in the press that employees of this class were not entitled to benefit if unemployed, the employer wrote to the Ministry of Labour, who replied that the applicant was an insurable person, and refused to refund. The letter was handed to the Association's solicitor, who stated that the Unemployed Insurance Act of 1920 did not apply to domestic service unless the person was so employed in a trade or business carried on for the purpose of gain. The fact that the person in this case had to keep the studio clean could not be said to make her an employee in the photographic business. Upon a similar point an application was made to Mr. Justice Roche, on June 13, 1922 (Wilkinson's application) in which a charwoman had been employed to clean a solicitor's office, and the judge held that she was employed in domestic service, and not in the business of the solicitor, and was, therefore, not insurable. The member who had raised the question, on having transmitted to him the solicitor's opinion that the woman was not insurable, promised to let the secretary know the outcome of events. Should the outcome be at variance with the solicitor's opinion, the secretary was instructed to press the matter further.

Another letter raised the question of Canadian copyright. The correspondent was advised before sending valuable work to Canada

to find out what protection there was against piracy, and on inquiry at the offices of the Canadian Government the secretary learned that the Canadian Copyright Act, 1921, was very similar to the British Copyright Act, 1911, save that certain registration clauses were inserted, whereby a print to be copyrighted had to be registered in Canada for protection at a cost of two dollars per subject.

Another correspondent referred to the need for a regulation size for passport photographs, some of his clients saying that his were too small, and others that they were too big. It was stated that there was no regulation size, but the experience of members of the council was that a size about 2½ by 1¾ in. elicited no complaints.

A member wrote as to a contract for certain postcards into which he had entered with a wholesale house, and which afterwards he wished to annul. The firm held him to his contract, or the payment of the gross profit of the transaction, together with certain damages for non-fulfilment of the contract. The solicitor's opinion was that the party having sent an order for the goods had entered into a binding contract, and that if an order was given and was afterwards repudiated, the injured party could claim, not the net profit on the goods but the gross profit. On the intervention of the secretary, who spent considerable time and much tactful diplomacy over the matter, the firm, whose original claim was for £11 10s., agreed to settle for £6 1s. The council expressed the view that the secretary had dealt with this case in a very able manner.

A member of council brought forward a case in which one of his photographs of a child had been reproduced, without permission or acknowledgment, as a sketch in an advertisement in a London daily paper. When the matter was first brought to the attention of those responsible it was argued that it was not an infringement of copyright because it was a line drawing, but the identity in every detail between the sketch and the original photograph was so complete as to make any suggestion that the first was not a copy of the second wholly untenable. The defence then was that the photograph from which the sketch was made was one in a book called "The Child in Art and Nature," which had an ambiguous foreword from which it might appear that any photograph therein could be copied.

A letter from a correspondent was read suggesting that a permit be issued for photo-canvassers, so that the police would know they were not fraudulent. It was agreed that this was not a matter for the council of the Association. Another member wrote complaining of unfair press competition at local events, when press photographers were welcomed, but their photographs were afterwards sold as prints and not merely reproduced in the press. He was advised to endeavour to come to an arrangement with the newspapers to do the work himself, receiving a small fee for reproduction, and reserving the right to take and use any photographs for sale.

Other correspondence dealt with by the secretary showed that he had advised on the matter of income-tax claims, charges for certain special work, infringements of copyright, costs of electric-lighting, studio construction (most painstaking advice being given in this instance, even to the drafting of plans), and the securing of a larger discount from a certain firm of dealers.

Commercial & Legal Intelligence.

NEW COMPANIES.

Pacific and Atlantic Photos, Ltd.—This private company was registered on October 18 with a capital of £1,000 in £1 shares. Objects: To carry on the business of photographers, manufacturers of cameras, stereoscopic and photographic apparatus and parts and optical goods, manufacturers and preparers of chemicals, plates, films and papers, etc. The subscribers (each with one share) are: A. O. Warren, 14, Bedford Row, W.C.1, solicitor; R. G. Clark, 125, Brecknock Road, N.19, solicitors' managing clerk. The first directors are not named.

Gilchrist Bros., Ltd.—This private company was registered on October 20 with a capital of £8,000 in £1 shares. Objects: To acquire the business of process engravers carried on by C. W. Gilchrist at Queen's Place, Claypit Lane, Leeds, as Gilchrist Bros. The subscribers are: C. W. Gilchrist, Glen Athol, Davies Avenue, Roundhay, Leeds, photo process engraver; H. Wright, 8, Moor Park Mount, Leeds, manager. C. W. Gilchrist is permanent governing director, subject to holding 100 shares, with £1,000 per annum as remuneration. Qualification £100. Secretary: J. A. Braithwaite.

Denton & Co., Ltd.—This private company was registered on October 17 with a capital of £2,000 in £1 shares. Objects: To acquire the business carried on at 36 and 38, Sheffield Road, Barnsley, as Denton & Co., and to carry on the business of photographers, photographic printers and photo lithographers, picture framers, manufacturers of and dealers in photographs, pictures, works of art, etc. The permanent directors are: G. H. Denton, 132, Park Grove, Barnsley; H. A. R. Denton, "Woodbury," Beech Grove, Barnsley (photographers). Qualification: 500 shares. Remuneration as fixed by the company. Registered office: 36, Sheffield Road, Barnsley.

News and Notes.

Colouring Lantern Slides.—Some months ago we reprinted from "Photo-Era" an article by Dr. Marcus D. Lovelace, on colouring lantern slides. The instruction given in the use of oil colours recommended itself so strongly to Messrs. Winsor & Newton that they have reprinted the article as a circular, in which also are given the prices for oil colours, brushes and stumps suitable for the colouring of lantern slides. A copy of the leaflet will be sent free on application to 37-40, Rathbone Place, London, W.1.

Photostat Machines.—Messrs. Alfred Herbert, Ltd., Coventry, England, ask us to correct the statement recently made in reply to a correspondent that the Photostat machines are supplied by the Kodak Company. Messrs. Herbert are sole selling agents, in practically all parts of the world, for the Photostat Corporation of Rochester, New York, and also are the sole agents for the supply of Photostat paper used in the machine. Mr. Littlefield, who acts for Messrs. Herbert in the selling of the machine in the London district, occupies rooms at the rear of the Kodak premises, at 40, Strand, London, W.C.2.

The Club Photographer.—The November issue of the "Club Photographer" obtains the staple of its contributions from members of the Exeter Camera Club. Dr. C. Beauchamp Hall writes on pictorialism in landscape, and Mr. F. Walker, in some notes on composition, describes a novel scheme for marking the ground glass as an aid to artistic composition. Mr. F. G. Tutton gives working details of the method used by him in making the three-colour transparencies shown at the recent R.P.S. exhibition, a contribution which we reprint on another page in the "Colour Photography" Supplement.

Photographing Fire-Flies and Glow-Worms.—The American scientific papers contain details of some interesting photographic experiments made by Dr. Herbert E. Ives, of Philadelphia, for the purpose of testing the illuminating power of fire-flies and glow-worms. Panchromatic plates were used for most of the experiments and exposures of one hour given. The insects, it appears, give a "flash" of about .004 candle-power, but the colour of the light given out is very different from ordinary illuminants; it is practically a monochromatic yellow-green. The complete paper, fully illustrated, may be found in No. 1,160 (Vol. 194, No. 2) of the "Journal of the Franklin Institute."

Postal Charges—From our own experience in the receipt of many letters daily, it would seem that there are a great many people who fail to realise the comparatively small weight of letter which can now be sent for the minimum three-halfpence. When the postal rates were reduced some time ago the maximum weight of a letter bearing a three-halfpenny stamp was reduced to one ounce. A one-ounce letter is quite a small weight in the hand, and our experience leads us to caution photographers as regards full pre-payment of letters addressed to their customers. Nobody can be expected to be favourably impressed by a letter drawing attention to So-and-So's portraiture if he has been surcharged a penny before obtaining possession of it.

Cinematographic Photographs by Wireless.—A Reuter telegram from New York states that moving pictures with the nearest film machine 1,000 miles away are promised by American engineers, who say they can transmit photographs by wireless. Members of the Society of Motion Picture Engineers, who met at Rochester (New York) last week, stated that the broadcasting of moving pictures by wireless has been successfully demonstrated. It was said that from a central broadcasting station films can be sent out by wireless so that a receiving set in communication can project the picture straight on to the screen as it is issued. There will no

longer be any need for projection machines and operators if the invention is successful. A wireless receiving set will replace them all.

ELECTRIC CURRENT AT POWER RATE.—As we go to press the hearing is imminent in the Court of Appeal of the application by the Wykeham Studios, for the setting aside of the judgment some months ago by Mr. Justice Swift, in the action taken against the Wykeham Studios by the Westminster Electric Supply Corporation, Ltd. Mr. Justice Swift held that current consumed in a studio arc lamp was current for power purposes, but he also held that the electric company was justified in charging a rate higher than that charged to other consumers of current for power purposes though lower than the full lighting rate. It was, no doubt, against this part of his judgment that the Wykeham Studios appealed. It is hardly possible that the decision of the Court of Appeal will be given in time for even brief mention of it in this issue, but most probably judgment will be delivered in time for a report to appear in our issue of next week.

SCOTTISH PHOTOGRAPHERS' GOLF.—The return golf match between the Glasgow and District Professional Photographers' Golf Club and the Edinburgh Society of Professional Photographers took place on the course of the Bruntsfield Club at Davidson's Mains on Friday, October 20. The match was played in foursomes, and the Glasgow players proved their superiority by winning every match. In the evening the visitors were entertained to dinner at the Haymarket Restaurant, under the chairmanship of Mr. J. R. Coltart. After dinner was served the toast of The King was duly honoured. Other toasts followed, and the health of the Glasgow players was enthusiastically drunk by their opponents. Mr. Coltart presented the cup to the winning team. The thanks of the company were extended to Mr. George Balmain for carrying out the arrangements for the day's outing and for the dinner, both of which had been an unqualified success. The company, after singing Auld Lang Syne, adjourned to the station, where Mr. Coltart kept up the fun until the train left.

BRITISH PROFESSIONAL PORTRAITURE.—Writing in "Abel's Weekly," Mr. Pirie MacDonald has some strong words of commendation for the British portraiture shown in the recent P.P.A. Congress exhibition, and urges his American brethren to do better another time. He says:—The British division was to me remarkably in advance of any British professional show I have ever seen—dozens of good things—almost every one of straightforward photography—of good control and few tricks, but very honest portraiture. The first prize went to a charming piece by the Mesdames Morter, which was by long odds the best piece of the section, but as a whole the British had every reason to feel "cocky" over the demonstration. The American section by comparison quite fell down. The work seemed small and slick—very different from the German failure—but nearly as bad in another way. The portraits were not convincing; they lacked the feeling that the people were portrayed but rather that the photographer had done a neat, quite pretty job. Of course, I can't mention names—it is not fair to criticise adversely exhibits that were sent by men who believed that they were doing the right thing, but it is true that many of the men who sent pictures would have been bitterly disappointed if they had seen their work on the wall. Pretty nearly the whole of the American exhibit seemed as though it was made of pictures that had sold—pictures that had sold because the sitter had been pandered to—pictures that were made for money—only for money—with no sign of their having been made from the joy of making them. Alongside of the British show they seemed commonplace and as a whole insipid—over-retouched—over-tickled—good negatives spoiled because the subject wanted to look pretty or young, in other words they lacked "guts." I feel that an exhibition of that kind should be the place where a man would send the things that he really believes in—his ideals and not his commonplaces—the things that he would prefer to make rather than the things that he is forced to make, for I do not conceive that it is a disgrace to make for your customers what your customers want, but I do feel that a man is giving away his birthright if he does not from time to time persist in making those things which he would prefer to make. A show like the Professional Photographers' Congress of Great Britain is the place where a man has the opportunity, perhaps the sole and only opportunity, of showing what is in his heart, and in preparing his exhibit he has the opportunity of doing what he prefers to do. George Harris is going over next year as their lecturer, and I hope that we may send an American exhibit which will make him feel proud that he is an American when he sees it on walls in competition with the work of the world.

COPYING HALF-TONES ON NEWSPRINT.

To the Editors.

Gentlemen, On page 660 of last week's "B. J." there is a reference to the work of copying half-tones from books and newspapers.

Some years ago I had a lot of this work to do, and after making many experiments I found that the best (dot-less) results were to be obtained by using a rapid plate, exposing fully, over-developing, and afterwards reducing the negative in a hypo-ferricyanide bath.

The full exposure and the over-development tended to close up the dots forming the high lights (in the original), while the reducer cleared away the dots from the shadow portions—or rather the spaces between the dots; anyway, little of the half-tone structure was visible.

How such negatives would serve for making lantern slides I do not know, but they gave the most perfect results on matt bromide paper.—Yours faithfully,

E. A. LEVY.

DARK ROOM LIGHT FOR BROMIDE PAPER.

To the Editors.

Gentlemen,—I am much interested in your correspondent's letter concerning the use of a red or yellow light for developing, etc. Has he, or she, ever tried the red and yellow together so that the light passes out through both? I have used this arrangement for a long time, and find it a perfectly safe one for plates or papers. Personally, I have no doubt that bromide papers can be exposed for a longer period under the combined red and yellow than they can under the separate colours, without fogging. The diminution of light can be easily remedied.—Yours faithfully,

E. J. FOSTER.

36, Lavington Road, Ealing, W.13, October 27.

Gentlemen,—With reference to your correspondent "Hyperion's" remarks on the above subject, while I can quite believe the results of his observations, I am afraid he has been led to a false conclusion as a result of them.

A red safelight only transmits the red rays, and a certain amount of the orange; an orange safelight passes the red, orange and yellow; and a yellow safelight the red, orange, yellow and green. These, of course, are only approximate statements, as I am not at the moment able to give the exact wave-lengths of the limits of transmission of standard safelights, such as those of Wratten and Wainwright.

It is obvious, therefore, that any material which is fogged by a red safelight is necessarily fogged by a yellow one, since the yellow safelight transmits all that the red one does, and more in addition.

I should therefore be surprised to hear of an experience such as "Hyperion's" with proper safelights, but many samples of "ruby glass" transmit quite an appreciable amount of blue or violet, and would be unsatisfactory for either plates or paper.

I think, therefore, it is very probable that "Hyperion" has used such a piece of glass and a yellow glass which absorbs the blue and violet more satisfactorily. Red sensitivity of the bromide paper would obviously cause it to fog in either a red or a yellow light.

The moral of "Hyperion's" experience would therefore appear to be that one should use a safelight of recognised quality and not rely on ordinary coloured glass.—Yours truly,

J. ARNGER HALL.

Imperial College of Science and Technology,
South Kensington, London, S.W.7.
October 29

To the Editors.

Gentlemen,—With the usual disclaimer, may I mention that, correctly used, the Wratten series of safelights provide a full margin of safety in the development of plates and papers? There

probably are other excellent varieties, but my own experience concerns this make only.

"Hyperion" seems to leave out the important question of intensity of illuminant, and a yellow, red, or green screen can hardly be expected to function correctly if, as I have seen used, a high candle-power electric lamp is employed almost touching the screen surface inside. These lamps, in my opinion, are entirely unsuited for dark-room lighting.

As a commercial photographer, I am at present using Wratten Series OO, yellow for papers, and II. for plates, illuminated by old type 8 c.p. carbon-filament lamps. These lamps are more suitable than the metal-filament lamps of equal c.p. Thus it seems that if the correct strength of light is used, placed well back from the glass screen, no unsafe "spot" can show itself. Supporting this, most of my prints (blocked out) showing pure white backgrounds never fog during normal time of development—two minutes at the most.

"Hyperion" refers to yellow being safer than red; whether or no this is the case matters little. The decisive factor rests, I think, with difficulty of knowing when the print has arrived at sufficient depth when using a red light for developing prints.

Many temporary contraptions used as dark-room lamps are badly designed, badly ventilated, and wrongly illuminated, so with light streaming on a white ceiling, in turn reflected on the print or plate, *plus* a melted gelatine screen through which almost white light emanates, fogging of plates and papers can only be expected.—Yours faithfully,

R. Beswick Willcock.

119, Roseneath Road, Urmston, Lancs, October 28.

To the Editors.

Gentlemen,—With reference to your correspondent's note that some bromide papers are more sensitive to red light than to yellow, I may say that it is possible to develop safely by a reflected yellow light extra rapid plates (non-colour-sensitive) which will be fogged by a red light of inferior visual brightness. The best working conditions are provided by time development with normal strength developer at a sufficient distance (variable according to the character of the yellow light, but generally never under 6 ft.) from the reflecting surface (wall, sheet of cardboard, etc.).

No doubt others also have noticed this peculiarity, which is probably due to those twins, "actinic value" and "visual intensity," as well as to the instinctive greater caution when a bright light is used.—Yours faithfully,

Louis Nell.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

Savoy Studio.—No agent in this country, so far as we know. For dyes, try Williams Bros. & Co., colour manufacturers, Hounslow, Middlesex.

W. H.—(1) Papers vary considerably as regards the facility with which they tone with liver of sulphur. The only advice we can give you is that you try one or two makes. (2) You can preserve pyro with citric acid, but it is a much inferior preservative to metabisulphite and less effective as regards preventing stain. We do not believe that there is any material which requires citric acid as a preservative of pyro.

J. C. R.—You require some form of bottom lighting, and we suggest, if electric light is available, that you instal one 1,000 c.p. lamp near the ground, and on the opposite side of your studio to the glass roof. Failing electricity, obtain a fairly large white reflector, and place it at an angle of about 30 degrees from the floor, and with one edge resting on the floor. This would reflect the light upwards, and so relieve the shadows under the nose and eyes.

C. W.— (1) For lens mounts and iris diaphragms write to C. Haseler and Son, Ltd., 94, Bridge Street West, Birmingham. (2) A stiff dextrine mountant would be very suitable for your purpose. White dextrine should be used, and 2 lbs. dissolved in 32 ozs. of boiling water. The mixture should be preserved by adding 10 minims of origanum oil, and the whole allowed to cool and set before use. The shellac mountant, mentioned in the "B.J. Almanac," 1922, p. 497, is also suitable.

J. F.—For glazing glossy bromide or P.O.P. prints, the glass or ferrotype plate should be rubbed over with the following mixture:—

1 oz. green soft soap of the British Pharmacopœia (obtainable from chemists).
15 ozs. methylated spirit.

Allow the soap to dissolve in the cold, apply to the plate on a piece of soft rag and polish off well before squeegeeing prints.

D. K.—There are two methods available for the photography of shop windows. One is to provide a large black curtain to fit to the awning blind, and which will reach across the full length of the window and hang down to about a foot from the ground. The camera is placed inside this, and a fairly long exposure at a small stop given. The other method is to make the photograph by night, using the ordinary window illumination for the lighting, a small flash being given fairly high up to illuminate the facia. The articles displayed in the windows should be placed against a fairly light background.

J. E.—The developer recommended in Freund's method of desensitising with potassium iodide is a special formula of hydroquinone and soda carbonate. The formula will be found on page 533 of the "B.J.," September 21, 1921. In your enlarger we should think the best method would be to fit your lens to a rack focussing lens tube, such as is used in projection lantern lenses. A tube of this kind could be obtained from C. Haseler & Son, Ltd., 94, Bridge Street West, Birmingham. If you send them the lens flange they could fit it securely to the focussing tube. You can obtain spectacle lenses from W. Heal, 58a, Hatton Garden, London, E.C.1.

N. P.—It is possible that the under-exposed patch on your negative is due to a spot of dust (or perhaps a fly) on the filter which was in front of your lens during exposure. The absence of definite shape proves that the object must have been some distance from the plate and possibly in front of the lens. If the plates had been touched during development, or if hypo had affected the plate, some more definite marking would have been the result. The fact that it did not occur again on any other plate proves that the cause was only a momentary one. While a half-plate negative is of better size than quarter-plate for contact work, we find that the extra weight is very much against the use of the former for hand-camera work. The majority of pictorial workers use the quarter-plate size, and some even smaller than this.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3262. Vol. LXIX. FRIDAY, NOVEMBER 10, 1922. Price Fourpence.

Contents.

SUMMARY.

In the Court of Appeal last week, before Lord Justices Bankes and Scrutton and Mr. Justice Eve, the appeal of Wykeham Studios, Ltd., against the recent judgment of Mr. Justice Swift was dismissed. The appeal concerned the rates which an electric supply company may charge for current consumed as power. The Court of Appeal has taken the view that a company may charge any rate up to the maximum lighting rate, and that any objection based on the protective sections of the Electric Lighting Act of 1882 must be made by the consumer, who must show that his consumption is similar in kind to that of others who are charged a lower rate. (P. 680.)

In a leading article we review the circumstances of the previous hearing and discuss what appear to us to have been the cause of the recent appeal judgment. (P. 674.)

In his article this week, Mr. J. Effel deals with the photography of hands and feet in the full-length figure, and specially emphasises the importance of study of hands and feet by themselves as a factor in studio portraiture. (P. 675.)

The Professional Photographers' Association has drafted a schedule for guidance in the fixing of charges for commercial photography. (P. 673.)

The question may be raised whether the larger accommodation at the Holland Park Hall in March next does not justify a re-assemblage of forces between the P.P.A. and the organisers of the Fair. (P. 674.)

In a recent communication from the Eastman Research Laboratory, Dr. S. E. Sheppard reviews the recent chemical work which has been done on the problems connected with the use of gelatine in the making of dry-plate emulsions. (P. 677.)

Mr. A. C. Banfield has recently described the method which he finds effective for diffusion of light in an enlarger, constructed without a condenser, for the minimising of graininess in the enlargements. He uses both opal and ground glass. (P. 674.)

At the Royal Photographic Society on Tuesday evening last, Mr. W. L. F. Wastell, in his presidential address, traced the development of the lantern slide from its pre-photographic days, and showed a very large number of slides prepared by different photographic processes. (P. 684.)

A correspondent draws attention to the light patch which may be caused on a negative by the flicking in front of the lens of the tassel of a roller-blind shutter. (P. 686.)

Dr. B. T. J. Glover, in a letter on page 687, gives particulars of the remarkable keeping properties of a metol-hydroquinone developer.

Lithographic methods for the rapid and cheap production of portrait posters are the subject of a contribution to "Photo-Mechanical Notes." (P. 681.)

A most admirable exhibition of pictorial landscape photography by members of photographic societies affiliated to the Royal Photographic Society remains open during the present month at 35, Russell Square. (P. 681.)

EX CATHEDRA.

The 1923 Almanac. Next year's edition of the "British Journal Almanac" is now well on its way to completion in the form in which it will be issued to the public, and, unless any unforeseen circumstances crop up, it should be published on or about December 1 next. As has been the case for many years past, practically the whole edition of 30,000 copies has already been ordered by dealers, distributors and shippers. Writing more than three weeks before the date of publication, it is reasonable to anticipate that no further copies will be obtainable from the publishers, Messrs. Henry Greenwood and Co., Ltd., by the time the books are on retail sale. We would ask that those who have not yet given a definite order for their copy to be reserved for them should note this announcement; otherwise, after publication, they may not be able to purchase in the ordinary way. The greater portion of the edition of the "Almanac" is ordered by dealers simply to the number of the requests which have been specifically received from their customers, and, therefore, in many cases, it happens that there are no copies for buyers who come in afterwards. We are anxious to make these facts clear, and particularly so since one or two London dealers a year ago ordered a greater number of copies than they had any reasonable expectations of selling, and of late have offered what were left at less than the published price. The incident is altogether exceptional, and steps have been taken to prevent its recurrence.

* * *

Charges for Commercial Photography. The Professional Photographers' Association has performed a useful work in codifying the charges which are made for commercial photography. Returns by a number of commercial photographers in London and the provinces have been obtained, and are averaged in a table which is published in the November issue of the Association's "Record." We are cautioned that the schedule thus obtained is copyright, and, although we have our doubts of its title to protection as a literary work, we have no wish to take advantage of a legal uncertainty, but will content ourselves with such extract as the Copyright Act permits us to make by way of fair and reasonable comment. The schedule sets forth the prices which may be taken as applying to a good standard of commercial work in sizes from half-plate to 15 x 12 inches. In the half-plate size the charge for taking a negative and supplying one print is 10s.; additional subjects taken at the same time, 7s. 6d. each. For further prints from a negative the charges are 2s. 3d. each, or 20s. per dozen unmounted; 2s. 9d. and 26s. if mounted. We are glad to see that an indication is given of the charge which should be made for delivery up of a negative which has been the subject of an order in the ordinary course. The price suggested is 12s. in the half-plate size. For

making and supplying a negative to order the figure is 18s. 3d. Messrs. George Hana and Jenkyn Griffiths, who have carried out the compilation, very properly dwell upon the difficulty of drawing up a table for hard-and-fast use. The quality of work is a highly variable factor to begin with; and it is suggested that prices, such as those we have quoted, may be reduced to two-thirds for work of medium grade or in quantity, whilst they may be doubled or further increased if special skill and attention are required on the part of the photographer. Extras, such as flashlight, working-up, orthochromatic photography, interior subjects, likewise make it difficult to establish a price-list which can be uniformly followed.

* * *

Fair and Congress. It is to be inferred from the necessarily brief references which have been made to the subject in their reports of council meetings that the Professional Photographers' Association have not yet come to a definite decision respecting the Congress which they will hold next year. Correspondence which we have published certainly indicates a balance of opinion in favour of a date for the Congress in March or April, and also its association with the Photographic Fair. We have no wish to influence the Association in any decision to which it may come, but, at the same time, the opinion may be expressed that two trade photographic shows in London in one year are inadvisable. Certainly the manufacturing and trading firms do not want two; and, from the standpoint of making the greatest public impression, there is no doubt that in 1923 more could be accomplished at a single trade exhibition than by dividing forces between the Fair and a P.P.A. trade show in the autumn. We imagine that the Holland Park Hall, at which the Fair is to be held, contains accommodation sufficient for the purposes of a Congress, and also sufficient for a display of professional portraiture. While the time between now and the Fair is rather short for bringing together a professional exhibit of the international character of that organised by the P.P.A. in September last, it does seem, in the interests of all concerned, that the possibilities of holding a Congress in the middle of March at the Holland Park Hall should at least be investigated.

* * *

Grain in Enlarging It is often found when making enlargements with the ordinary type of condenser lantern that effects are produced the graininess of which is quite out of proportion to the quality of the negative image. Retouching marks also show very badly and seem to appear more prominent than would be expected. This is due, according to a lecturer at the Royal Photographic Society, to the uncorrected aberrations of the system used; tiny diffraction circles surround each enlarged grain of silver, while retouching marks are paralleled on both sides with diffraction lines. Many efforts have been made to correct this defect, the simplest suggestion being to insert a piece of ground glass between the condenser and the negative. This minimises the defect, to some extent, but does not eliminate it altogether. Chiffon used in front of the lens softens the image considerably, but even with this extra softness the diffraction marks are not removed. The lecturer, Mr. A. C. Banfield, suggested a method which he has adopted with marked success, and which enables an enlargement to be produced entirely free from grain. The light is diffused by the aid of a piece of ground glass supplemented with a sheet of "flashed" opal, the condenser being discarded altogether. The ground glass should be considerably larger than the negative to be enlarged, and should be placed as near as possible to the source of light. A sheet of "flashed" opal is then placed in close proximity to the negative, but at a distance of at least four inches from the ground glass. The illuminant in this system of enlarging must of necessity be of fairly high power—a 15-ampere arc or 1,500 watt half-watt lamp is used. The lamps are so fitted that each may be used separately, and may easily replace each other. Owing to the large amount of heat given off by these lamps, it is necessary to provide some means of effective ventilation, and it was suggested by Mr. Banfield that the apparatus be fitted to an aperture in a wall separating two rooms. The lamps were then situated in one room, and the negative carrier with the camera and lens in the other. When enlarging from small negatives, *i.e.*, up to and including half-plate, the ground glass may be dispensed with, the opal giving an evenly-diffused light over the whole surface of the negative. It was pointed out that the "pot" opal type of glass was not suitable, as it absorbs far too much light, without any gain in diffusing power. A reflector helps considerably when used behind the half-watt lamp. But it should be of fairly large size, the "Barkay" reflector being recommended as very suitable.

CHARGES FOR STUDIO ELECTRIC CURRENT.

It will be remembered that in the early part of the present year action was taken in the High Court, before Mr. Justice Rigby Swift, by the Westminster Electric Supply Corporation, Ltd., against Wykeham Studios, Ltd., in respect to the charges for electric current used in a studio arc lamp by the defendant firm. The proceedings were reported very fully in our columns at the time.* Although the circumstances of the dispute are of importance to all photographers using electric current for purposes other than ordinary illumination of premises, they may, perhaps, have escaped the recollection of many readers, and, therefore, it is well that we should briefly recall them before proceeding to refer to the judgment given on Thursday in last week, November 2, in the Court of Appeal, by Lord Justices Bankes and Scrutton and Mr. Justice Eve, as the result of application by Messrs. Wykeham Studios for the decision of Mr. Justice Rigby Swift to be reviewed in the higher Court.

The Wykeham Studios, Ltd., had been supplied with current for their arc lamp through a separate meter at the ruling power rate, but subsequently the electric supply company charged first the full lighting rate and afterwards a rate less than this latter, but greater than the power rate which was charged at the same time to other consumers. The Wykeham Studios disputed the right of the electric company to charge such higher rates, with the result that they were sued in the Court for an amount which, it was agreed, represented the difference between the lowest power rate and the rate which was demanded from the Studios. The judgment of Mr. Justice Swift went against the defendant firm, for, while it was held that current supplied to an arc lamp in a photographic studio was correctly classed as current for power purposes, it was held, on the other hand, that an electric supply undertaking has the right to vary its charges for current for power purposes. In the hearing of the action a great deal of discussion ranged round the two sections, Nos. 19 and 20, of the Electric Lighting Act of 1882, which enforce uniformity in the terms of supply and prohibit preference to one consumer in comparison with another. In particular, the action turned on the application of the words "under similar circum-

* *B. J.*, 1922. May 19, pp. 297-298, and May 26, pp. 314-316.

stances," which are contained in Section 19. This section runs:—

> Where a supply of electricity is provided in any part of an area for private purposes, then, except in so far as is otherwise provided by the terms of the licence, order, or special Act authorising such supply, every company or person within that part of the area shall, on application, be entitled to a supply on the same terms on which any other company or person in such part of the area is entitled *under similar circumstances* to a corresponding supply.

As we pointed out in a discussion of the judgment, published in our issue of May 26 last, Mr. Justice Rigby Swift's decision appeared to have been based on an entire misapprehension of the circumstances in which current for power purposes is consumed by photographers. The learned judge said:—". . . . . the photographers, speaking generally, are not taking current for power purposes under similar circumstances to other manufacturers. Their lamp is not burning regularly and for fixed hours during the day or night, but is intermittently used as occasion necessitates for the taking of particular photographs." He appeared to assume that photographers use current in this intermittent fashion, and that other consumers of current for power purposes use it constantly, that is to say, at a regular rate and without intervals of disuse.

The Court of Appeal has now confirmed the judgment of Mr. Justice Rigby Swift, and Lord Justice Bankes, in delivering judgment without calling upon the respondents' counsel, set forth his decision in more explicit terms than was done in the lower Court. He agreed with the previous judge that current consumed in an arc lamp is current supplied for power purposes, having regard to the definition of power purposes. And he also held that the circumstances of the consumption were not similar to those of other consumers of current at a power rate and that the supply was not a corresponding supply. Indeed, he was, perhaps, more explicit than Mr. Justice Swift in taking the view that the circumstances under which power current is consumed in photographic studios are different from those on the premises of all other consumers of current at a power rate. Mr. Blanco White, for the appellants, had laid great stress upon the fact that no evidence had been forthcoming from the electric company in the previous action as regards the difference in the circumstances which justified the supply undertaking in charging a power rate higher than the minimum, and he argued that the onus of supplying such evidence was upon the electric company. Lord Justice Bankes, however, definitely took a contrary view on this point. He said, in effect, that an electric supply company under its powers may charge any power rate it likes up to the maximum lighting rate, and if a customer objects to the higher rate he must bring forward evidence to show that the circumstances of his consumption are not worse, from the point of view of the electric supply company, than those of other consumers of current at a power rate. In our opinion, after listening to the arguments and judgments in both the Courts, it is very likely that events would have taken a different course if this particular question of the circumstances of consumption, in comparison with those among other power users, had been fully investigated by the examination of witnesses in the first instance. It is unfortunate that in the lower Court the parties reciprocally agreed to certain matters; the fact that there was a vital disagreement regarding the circumstances of consumption appears to have been overlooked until it was too late to rectify the omission. In the absence of evidence, both Mr. Justice Swift and the Judges of Appeal appear to have made large assumptions respecting this question, which obviously is the crux of the dispute. It was taken for granted, with a readiness which seems astonishing when one bears in mind the meticulous accuracy which judges demand in other matters, that users of electric current for photographic portraiture come in a class by themselves on account of the highly intermittent use which they make of their current supply. Nobody, we suppose, denies that their use of current is intermittent; the question is whether it is more intermittent than that of other consumers obtaining current at the minimum power rate. It seems to us that such a question can only be answered by evidence of fact, and it is for that reason that we regret the absence of opportunity in the proceedings for the facts to be ascertained. Cases may perhaps arise in the future when similar conditions will be investigated in a Court of Law more closely in reference to realities. For the present, the effect of the judgment is perfectly clear. It is, that an electric supply company shall charge a power rate to users of current for studio portraiture, which rate may be anything from the minimum power rate to the full lighting rate. Also, according to the judgment, a photographer who objects to a charge which he considers excessive in comparison with that charged to other users of current at power rate is required to show that his consumption is similar in kind to that of others who are charged less than he is.

WITH A PORTRAITIST IN THE STUDIO.

[In the present paper of the series, which is being contributed by Mr J. Effel, the writer, in dealing with the photography of hands and feet in the full-length figure, lays special stress on the study of the posing of hands and feet by themselves. By so doing the portraitist will quickly recognise ugly poses of these parts of a full-length portrait. Mr. Effel gives some homely examples of methods which may be used in training the eye to sensitiveness regarding the position which hand or foot may occupy in a portrait.]

X.—HANDS AND FEET: THE FULL LENGTH.

Other times, other manners, George, as the French put it. The last time I was in Paris I visited an art school where formerly I had studied. I found myself regarding a full-length drawing at which a young pupil was working. The sketch was proceeding on lines totally different from what I might call the traditional South Kensington method of thirty years ago. The paper seemed covered with squares, crude triangular figures, and other shapes which were used as guides for the different parts of the figure. What surprised me most was that after getting those shapes to his satisfaction—and to the satisfaction of the very exacting master—a foot or a hand, or whatever took his fancy, would be finished without the faintest reference to the whole. Of course, a moment's reflection ought to have proved that if the skeleton forms were right in shape and proportion the details of the parts were bound to join up and match perfectly, but, as I say, it was new to me.

Now we are not going to discuss different methods of teaching drawing, but whatever criticism might be levelled against the system I have outlined, there can be no doubt that a portrait photographer must be able to photograph satisfactorily the head, hands, feet, and other parts of the human

figure, as viewed from all angles, and in different attitudes, before he can hope to produce full-length pictures of any worth. It is as preposterous to attempt a picture full of problems, without previous study, as it would be presumptuous of the young musician to attempt a difficult rhapsody of Liszt before he had, in practising scales and chords, mastered the details of which the intricate composition was built up. When we started these lessons, George, our first consideration was the bust portrait. We have gone over a good deal of ground, and I have been pleased to see that my lessons have borne fruit by the experimental plates you have exposed. You have now blotted out from your life the meaningless two-eared front face, the hall-mark of the ignorant dud. You are using far less light than formerly, and your "modelling" has gained enormously. Where I still see faults—and, rest assured, my lad, I'll point out every one—in selection and treatment, they are entirely due to your lack of knowledge. Without wide knowledge, or extraordinary genius, experimenting is largely a waste of time. While, then, in the finer points of head and shoulder work you are not well enough instructed to enable you to go much further, you possess a good working knowledge of the posing and lighting of the top end of a full length. In our three-quarter length experiments you have seen me working for different effects with the hands, and you have heard me lecturing about the placing of the feet. But beyond vague generalities, I have not imparted to you sufficient knowledge of the possibilities in photographing hands and feet; I have never even mentioned "the dignity of the human spine," the legs and arms in straight and curved effects regarded from the æsthetic rather than from the anatomical aspect, and the modifying part played by clothing. The student of portraiture should always have at the back of his mind the consideration of the nude. Leighton, I believe, worked from the nude figure and then superimposed draperies, through which one could discern the lovely forms underneath. Certainly in the rhythm of his draped figures there is a great lesson for the portraitist. I am not about to suggest that a photographer could work on the method of Lord Leighton, yet the covered limb must always be regarded *as* a limb, and the old question put to ourselves: "Shall I disclose, or shall I hide?"

Dress is of two kinds, that which shows off the figure it covers, and the other sort, which is purely decorative or fashionable with but little reference to the form of the wearer. The hands are usually uncovered, so we will consider their treatment first in the building up of full-length portraits.

I remember the late Wilson Barrett saying that even as an old and experienced stage performer he was frequently at a loss as to what to do with his hands. How much more difficult, then, must it be for the ordinary man or woman who has never given a thought to deportment, and for the photographer who is suddenly called upon to make a graceful portrait out of such unpromising material. There are two ways of meeting the case: the hands may be hidden, or the portraitist must know thoroughly what to do with them. Let us think of the latter way. Even the hiding of the hands skilfully requires a little knowledge. The difficulties with the hands are usually that they are too big, and in a photograph have the knack of looking more awkward still, the customary rendering being of the "Mutt and Jeff" school.

I want to make it quite plain to you, George, that a photographer is considerably handicapped when his work is compared with that of the painter, particularly when a short focus lens is in use. For that reason there are attitudes and effects quite in common practice with painters utterly impossible with the camera. You remember in the early days of the war a poster of Lord Kitchener pointing a finger straight out of the picture. It was an arresting bit of work, but no photographer could have produced it. Another point to remember in this connection is that far more retouching, faking, and idealising is possible with the man who works with pencil than with the camera artist. So that when the camera tends to increase the size of the hands when they are slightly in advance of the body the photographer must know how to make them appear neat.

By what means can we make a large object look small? Assuming the same distance from the lens, I cannot see how the proportion of a football to other objects in a picture can be altered, but most objects other than the spherical have many different shapes when viewed from different angles. Take the ordinary household plate—you'll find one somewhere about the printing room; just bring it here, George, and we'll have this matter out. Hold the plate full front face to the camera—thank goodness, a plate hasn't ears!—and we have a perfect circle. Now hold it out, showing its profile. Close one eye—always remember your camera has only one—and look at the edge. Little but a narrow line is now visible. That plate is approximately 8 in. in diameter, and it would require a box 8 in. square to hold it flat. But when you think of the side face of the article you will see that 8 in. by 1 in. is its size, sectionally regarded. Tilt the plate a little, George, and you find that the round object appears as a more or less attenuated oval, and when you get round to the three-quarter view you will find disclosed, in addition to the oval of the business side, another set of contours at the back. Well, George, if so much variety can be got out of the common or breakfast plate, surely the human hand should not discourage us.

Lay down the plate, George, but keep the little demonstration in your mind. Now hold your hand out before you in a similar position to the view of the plate at its biggest. We are looking at the palm of your hand, and the fingers and thumb are close together. It looks as stiff and solid looking and as devoid of the sense of movement as we can show it. Except that we know differently, the hand might stick out at the back for inches, indeed conjurors can either "palm," or hide behind the hand comparatively large objects, when showing the reverse side square on to the audience. Bear with me, George, and you'll see the point presently. You remember my strictures about the front face. Well, the same remarks apply to the hands. A photograph should tell the story of the form of the sitter. In a full length portrait, in what the English call the tout ensemble (and the French call something else), the more of the physical and facial characteristics unfolded, the more faithful the likeness. Cromwell notwithstanding, I have no great predilection for featuring warts on strong silent men or knuts trying hard to be different (by being like somebody else) under the impression that I am rendering "character." History is silent concerning the reply of the artist to the Protector. Had I been in the painter's place, my sitter would not have had a walk over. I would have said to him, "Oliver, old onion, your theories of government may be all right, but you're off the rails about art. Here I have brought my great genius to bear upon the problem of rendering immortal the real Cromwell, as faithfully as my exceptional training and talent in the use of pigment can convey to the world what manner of man you were, how every trait of your character was etched deep into your face by your own strong convictions, and now you come this fool talk about warts. This was decidedly a thing for an artist to ignore; *a wart has no character, and might as easily disfigure the face of a fathead as a roundhead.* Don't be a plum. Oliver, I think I have given you something of a Roland. A man who could cut off the head of a monarch shouldn't grumble if an artist profits by the example, and lops off the head of another useless growth."

Photographers, we are told, George, have not read "The Outline of History," yet I think we all know something about Cromwell. He was a background for warts.

Now, back we go to the full length and the story it ought to tell. Why are big feet like warts, George? No, it has nothing

to do with protectors; the answer is because they are not worth immortalising. Fortunately the interdependence of the toes presents no problem to the photographer, but the hands are well worth the study we can give them, for there are great and characteristic differences in hands, frequently quite ignored by the superficial worker. In his admirable book on oil painting, Mr. Solomon, in illustrating how to draw a hand, tells that the successful student will have a drawing, not of a hand, but of *the* hand of the model. Now, as in literature, there is realistic treatment and what is known as idealism in photography. Many a clever, honest portraitist would starve to death if he only dealt in realism. Never forget, George, that I am concerned about your ability to produce photographs that will earn you money, not about the making of prints for exhibitions. Well, then, think of the hands again. The great thing to know is not how to show character by the hands, but simply how to photograph hands so that they look graceful instead of awkward, and to have a good stock of tricks of camouflage and occupation to show them to the best advantage.

It is just the plate illustration over again, except that the hand may be bent, or the fingers folded, yielding infinitely more variety. I would say to you, George, always think of the edge of the hand, and avoid as far as possible the back view. There is one mistake frequently made by good portrait photographers, and seldom by painters or art students, that is the view of a lady's hand in repose; a well bred woman will always sit with her hands on her lap, palms upwards. There are a score of great pictures in my mind's eye affording excellent examples of this, Gainsborough's Duchess of Devonshire being probably the best known. A walk round a picture gallery, or, better still, a few of those excellent little books illustrating the work of great painters, will educate you *if you know what you are looking for*. Few, who are not students, know anything about the full length and group work of Greuze, his heads being more widely known. Yet for a shilling you can get a book of reproductions of his works. I'll lend you my copy, George, and I would ask you to particularly notice the hands. Short of the idealistic treatment, you ought to get the hands as well as the masters. It is simply a question of knowing the tricks. Greuze knew the whole bag full.

I am giving you a print, George, of different poses of the hands, and wish you to add it to your scrap book. Needless to say, I do not want you to go copying those regardless of your subject, but I certainly think that until you have a score of different or alternative placings in your mind, when your sitter enters the studio, you are not fully equipped to make full length portraits. First go over all your old work, and blot out all the clenched fist studies. Don't shirk the difficulties by placing hands in pockets, or behind the back, if those are not otherwise easy poses. Give the hands occupation, only make it suitable. Flowers are excellent for covering awkwardness, but avoid roses which have been kicking about the studio for months. Our old friend the book should be a magazine, indeed from the studio price list to the pre-war telephone directory there should be variety at hand. A child might reasonably be occupied with Tiger Tim's annual, where a book would be ridiculous. A particularly ungraceful hand can be placed quite naturally under the cover of a good sized monthly, the other one farthest from the lens half hidden while occupied naturally enough turning over a page. A little thought and constant experiment with different material will give you a wide range in the posing of hands. Above everything else, watch the hands of the ordinary mortals with whom you come in contact daily. Allowing for the difficulties of rendering them as a painter can- difficulties inherent in photography, and which actually favour us in truthfulness—there is much more to be done in observation, in study, and in practice than is usually attempted. Study the hands well, George, in action, in repose, think of them as useful, as decorative, as dainty, as strong and gnarled, or delicate and fragile. Turn them, light them, trick out the fingers, make them button gloves, play with flowers, swing sticks, twirl the fingers of each other, clasp them, rest the head on them, do anything you jolly well like with them so long as you always think of the most beauty, and do not make too great a departure from naturalness. Face the problems on their merits, and have plenty of courage. After all, the hands of an old man may express more in awkwardness, than in studied "grace," and the bejewelled hand of a rich lady may be of far greater value to the portrait photographer than pleasing contours. The most I can ask of you, George, is that you always know what you are doing, when you are subordinating art to expediency. Experiment away then with your full lengths and be merciless in criticism of your own work. Only when you are capable of taking dozens of portraits featuring hands without faults and repetitions, only then will I allow you to say, "Confound those bally hands, I'm going to take a bust head of this clumsy sitter."

J. Effel.

THE MODERN CHEMISTRY OF GELATINE.

(In a recent communication from the Eastman Research Laboratory Dr. S. E. Sheppard reviews some of the most recent work which has been done in the complex problems which concern the part played by the gelatine in the making and use of gelatine dry-plate emulsions. These include the effect of impurities in the gelatine which reduce sensitiveness; viscosity and setting point of gelatine solutions; mechanical strength of jellies and their capacity for swelling; and the behaviour of gelatine in hardening fixing baths and on drying. The paper is being published in the United States in the "Journal of Industrial Engineering Chemistry.")

Modern photography is almost as much dependent upon gelatine as upon silver salts. The work upon gelatine which is being carried on under the author's direction at the Research Laboratory of the Eastman Kodak Company is naturally chiefly devoted to its use in photography, and the following is an outline of the function and behaviour of gelatine in photographic processes.

The two chief classes of photographic material in which gelatine plays a rôle are :—

(a) Gelatine silver halide emulsion.

(b) Bichromated gelatine layers.

In the former the part of the gelatine is fundamentally that of a binder or suspending medium for silver halides, for silver derived from these, or for compounds derived from the silver by reactions subsequent to development of the latent image. In all these cases, the special physical and colloid chemistry of gelatine is of great importance for correct understanding of the behaviour of the plate or film.

In the second class cited, the gelatine becomes, through the photo-chemical decomposition of the bichromate, itself art and part of the image.[1] In fact, the whole practice of photographic and photo-mechanical processes with bichromated gelatine, gelatose, etc., depend upon radical modifications of the properties of these colloids produced by tanning reactions, either directly or indirectly photo-chemical. This class is of more importance for photo-mechanical than for strictly photographic procedure, and will not be discussed directly in this paper.

Introduction of Gelatine into Photographic Emulsion Making.

Although he had forerunners, the credit of preparing the first

1 It may also act as a binder for a pigment, but the pigment is inert.

gelatino-silver bromide emulsion is generally ascribed to Dr. Maddox, of Liverpool, England (1871), Fig 1. His emulsion was prepared by suspending silver bromide with excess of silver nitrate in gelatine acidified with nitric acid, and development was effected with acidified pyrogallol, to which more silver nitrate was added.

Fig. 1.—R. L. Maddox.

Maddox's emulsion, therefore, belonged to the first of the two main classes of sensitive silver halide preparations:

A. Silver halide formed in presence of excess silver salt. Includes wet collodion, collodion emulsion, and most printing-out emulsions.

B. Silver halide formed in presence of excess of soluble halide. Includes both positive and negative emulsions for chemical development.

It was the previous discovery of alkaline development (of collodio-bromide emulsions) by Russell which made Maddox's experiment lead the way to the second class of emulsions, which hold first place in importance in modern photography.

Gelatines for Emulsions.

The value of gelatine for emulsions depends both upon its physical properties and its chemical composition. It is not necessary to amplify the statement that gelatine is pre-eminently an emulsoid or solvated colloid. The high degree of reversibility of the transition

$$\text{Hydrosol} \rightleftharpoons \text{Hydrogel}$$

at conveniently attainable temperatures is a fact of first importance for its use. The formation of the jelly from the hydrosol is termed *setting*, the converse passage from the jelly to the fluid solution *melting*, and it has been customary to speak of *setting points* and *melting points*. By the former was understood the temperature at which the solution congealed; by the latter, the temperature at which the jelly liquefied. These temperatures are not coincident, as in the case of a crystal, and, corresponding with this thermodynamic indetermination, are only empirically definable by experimental conventions. The writer and S. S. Sweet[2] have shown that the "setting point concentration" curve, or the "melting-point-concentration" curves, determined under standard conditions, are more characteristic of a gelatine than single setting or melting points at one concentration, although if these are taken in the region where the "point" varies linearly with the concentration—10 to 20 per cent.—a satisfactory practical comparison is usually possible. Technical gelatines are roughly classified as "hard," "medium," and "soft," in terms of the melting point. Using the writer's apparatus, the following typical results were obtained for 10-per-cent. jellies:—

No.	*Kind of Gelatine.*	*Setting Point.*	*Melting Point.*	*Trade Description.*
1.	Glue (domestic).	18.2° C.	19.8° C.	Glue.
2.	Gelatine (domestic).	23.2° C.	25.8° C.	Soft.

In common with other physical properties, the "setting" and "melting" points are largely controlled by the hydrogen ion concentration. With most photographic gelatines this corresponds (in 1 per cent. solution) to a p_H between 5 and 6, under which condition no great variation results. But, as noted later, this important constant should always be determined, in order that due adjustment be made. Apart from this, or the presence of other "ionogens" in considerable amount, the value is chiefly determined by the proportion of hydrolysed to unhydrolysed gelatine. The value is lower, the more advanced the hydrolysis, which converts the protein over into a mixture of proteoses, peptones, and amino-acids.

Recent work of C. R. Smith,[3] R. H. Bogue, and E. T. Oakes[4] has indicated the highly interesting possibility of a thermodynamically definite "transition point" between "sol" and "gel" forms of gelatine. Smith concluded, from polarimetric measurements of the muta-solution of gelatine solutions, that the point lay between 33 deg. and 35 deg. C., and suggested that it corresponded to a bimolecular condensation of gelatine "molecules." Bogue, from measurements of the plastic yield of gelatine hydrosols, finds transition at about 35 deg. C., whereas Davis and Oakes, from very valuable studies of the change of viscosity of gelatine solutions with time, have fixed it very precisely at 38.03 deg. C. Some doubt may be felt at present as to the complete validity of these conclusions, that is, as to whether the "transition point" is independent of the concentration and origin of the gelatine.[5] But the suggestion that what was formerly termed the thermal "lag" of gelatine solution is a case of "suspended transformation" is of great theoretical importance, while the attainment of temperatures of invariance of such a property as viscosity is of equal practical weight.

In the preparation of emulsions, including the coating, it is the properties of the hydrosol which are most interesting. They may be divided as follows:—

(1) Protective action.
(2) Viscosity.
(3) Influence on sensitiveness to light.

(1) *The protective action of gelatine*, e.g., in the case of gold and silver hydrosols, is well known. Values for the "gold number," by Zsigmondy and others, give, e.g.:—

Colloid.	Gold Number.
Gelatine	.005 — .01
Casein	.01
Egg albumin	.06 — 0.3
Dextrin	10 — 20.

In a recent paper[6] it has been shown that the "gold number" of gelatines depends upon the dilution of the hydrosol, increasing therewith, and upon the age of the solution. It was not found possible satisfactorily to differentiate technical gelatines on the basis of their "gold numbers."

In the case of silver halide emulsions, this protective action, which involves inhibition of agglomeration (and crystal growth) of amicrons, is doubly important. First we may note that if silver nitrate and potassium bromide solutions, with slight excess of bromide

$$AgNO_3 + KBr = AgBr + KNO_3$$

are mixed in darkness, and the precipitated silver bromide washed with water, then it is found to be immediately reducible by any of the usual developers. If quite small amounts of gelatine are added, the reduction is greatly slowed down, and this inhibition increases rapidly with the amount of gelatine, till a maximum effect is soon reached. Sheppard and Mees attributed this protective power largely to the insulation of the silver halide particles from dust, etc., nuclei, with which effect is associated a delay in aggregation of silver amicrons to form larger nuclei. It is possible to prepare colloid-free silver bromide layers, which can give a developable image, but "chemical fog" occurs much earlier.

The same protective effect is, however, at work in securing fine-grained precipitates of the silver halide. Emulsions in which the silver halide particles are largely of submicroscopic dimensions are the so-called Lippmann emulsions of silver bromide, for interference photochromy, and silver chloride positive emulsions, i.e.,

for lantern slides and transparencies. For negative emulsions, of higher "speed," the grain is considerably coarser, being in fact definitely crystalline[7], and one great advantage of gelatine over collodion is that it permits the growth and opening of the crystals.

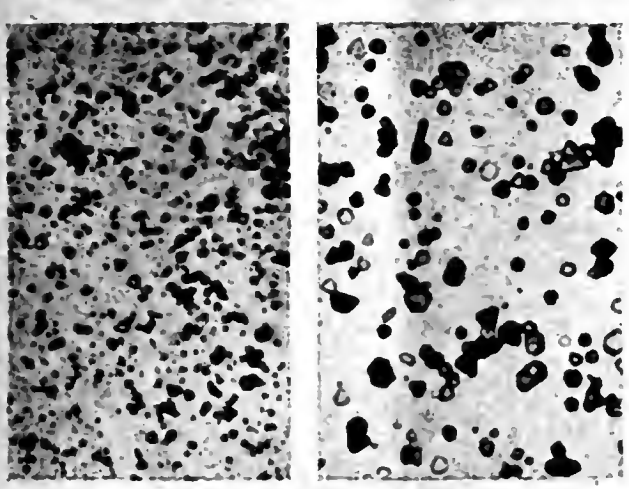

Fig. 2.—Silver bromide grains of emulsions. Magnification, about 2,500.

Crystals in Gelatino-Silver Bromide Emulsion.

Heating suspensions tends to agglomerate the particles and lessen the dispersity, and since negative emulsions are "ripened" by heat to increase their sensitiveness and density-giving power, it has, therefore, been supposed that high-speed negative emulsions, with coarse grains, simply represent a stage produced from fine-grained emulsions by heat treatment and Ostwald ripening. This is not the case. The conditions in the preparation of the coarser-grained "high-speed" emulsions are different, and, in particular, the concentration of the reactants is higher, and that of the gelatine is lower. The importance of these factors is very definitely outlined, if not yet completely covered, by Von Weimarn's theory, and is illustrated in the following diagrams :—

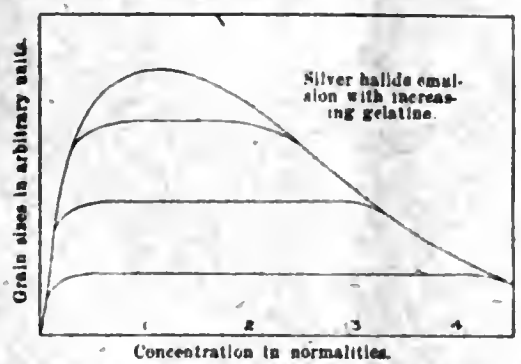

Fig. 3.—Influence of gelatine on average grain-size of silver bromide.

The influence of increasing concentration of gelatine in extending the region of minimum dispersity, but lowering the dispersity itself is illustrated here. Recent work of Odén[8] indicates that the degree of dispersion of the primary grains of precipitates (gelatine absent) steadily diminishes as the concentration decreases. The maximum observed by Von Weimarn and others is due to secondary aggregation; this may, however, be of equal importance technically.

(2) Viscosity.

A. *At one concentration*, and at one temperature preferably not below 40° C. and not above 50° C.

Factor.	*Influence.*	*Authority.*
i. H-ion activity	Viscosity is a minimum at p_H 4.7–4.8, the iso-electric point. Rises to a maximum p_H 2 to 3.3, and again between p_H 8 to 10.	J. Loeb, R. H. Bogue, E. T. Oakes. Oakes' conclusions differ somewhat from Loeb's.
ii. Cations, e.g., from ash constituents. Na .. mono Ca .. di- Al .. tri- Fe .. tri-	Viscosity effect depends upon concomitant p_H variation; when $p_H > 4.8$ gelatine combines only with cations. At same p_H monovalent cations give same viscosity, polyvalent cations lower than monovalent.[9]	J. Loeb.
iii. Anions, e.g., Cl^I .. mono	When $p_H < 4.8$, gelatine combines with anions only. At same p_H, the monobasic acids HCl, HBr, HNO_3 and acetic give identical effect, oxalic, tartaric, succinic, citric and phosphoric nearly the same as the monobasic acids. H_2SO_4 gives a lower value.[10]	J. Loeb.
iv. Non-electrolytes. ..	Methyl and ethyl-alcohol lower viscosity, glycerol and sugars increase. (Compare effect on water.)	
v. Composition & hydrolysis.	Gelatine, even when free from congeners such as mucin, is a mixture of unhydrolysed and hydrolysed protein. The greater the proportion of hydrolysates (proteoses, peptones, amino-acids) the lower the viscosity.	Levites, von Schroeder, R. H. Bogue.
vi. Age of solution	—	—
vii. Rate of Shear	Inhomogeneous systems, as suspensions, emulsions, colloids, have a lower limit on yield point of shearing stress, below which the displacement is not proportional to the stress. Gelatine sols show "plastic yield," according to concentration and temperature.	E. C. Bingham

B. *Concentration variable.*

Concentration.	*Ceteris paribus*, the viscosity of a gelatine sol increases very rapidly with concentration. The concentrations region of interest, photographically, is from 5 to 10 per cent.	R. H. Bogue finds that Hatchek's formula is inapplicable *per se*, but may be semi-empirically corrected. Davis and Oakes find Arrhennius' formula more satisfactory.

C. *Temperature and transition.*

i. Temperature.	Viscosity decreases with rise of temperature. Furthermore, the rate of hydrolysis increases (depending again upon p_H). From recent experiments we found it to be quite perceptible at high and low values of p_H, even at 50° C.	S. E. Sheppard and F. A. Elliott.
ii. Transition ..	From work on the muta-rotation of gelatine sols C. R. Smith concluded that a transition-point between *sol* and *gel* forms of gelatine existed at 34–35° C. Bogue measured the viscosity of gelatine sols at different rates of shear, and deduced from the occurrence of plastic yield a value (about 35°)	C. R. Smith, R. H. Bogue, E. T. Oakes.
	Experiments in this laboratory show plastic yield to occur at different temperatures according to the concentration.	S. E. Sheppard and F. A. Elliott.
	Davis and Oakes have attacked the problem from the standpoint of time-variations of viscosity and found for their material, 38.03° C., a temperature of invariance. Above or below this temperature the gelatine-water system may be in a state of suspended transformation.	S. E. Sheppard.

(To be continued.)

8. Sv. Odén, Arkiv för Kemi (Stockholm), 7, No. 26 (1920).
9. Complications due to precipitation of membranes by trivalent cations excluded.
10. The other polybasic acids combine with gelatine as monobasic.

ELECTRIC CURRENT AT POWER RATE.

JUDGMENT IN THE COURT OF APPEAL.

In the Court of Appeal, on November 2, before Lord Justices Bankes and Scrutton and Mr. Justice Eve, judgment was given on the application by the Wykeham Studios, Ltd., of Victoria Street, Westminster, against the decision of Mr. Justice Swift, in the King's Bench Division last May, in reference to the claim brought by the Westminster Electric Supply Corporation, Ltd., for payment for electric current used in a studio arc lamp. The appellants in the present action were thus the defendants, namely, the Wykeham Studios, Ltd., in the action in the lower Court. The respondents were the previous plaintiffs, namely, the Westminster Electric Supply Corporation, Ltd.

Mr. Blanco White appeared for the appellants and Mr. W. S. Kenney represented the respondents.

Mr. Blanco White, in opening the appeal, said plaintiffs claimed £82 10s. 9d. as the price of electricity supplied to the defendants who were photographers carrying on business within the area supplied by plaintiffs. £40 5s. 10d. was admitted by defendants to be due, and was paid. The amount in dispute was the balance, £34 12s. 7d., and as to that the defence was that it represented the electricity supplied for use in a powerful arc lamp in defendants' studio, which was a special sort of lamp used by defendants for the purpose of creating a very great light to be switched on at the exact moment that a photograph was being taken. The defendants had their studio wired in the ordinary way for incandescent light, but exactly at the moment a plate was exposed this strong light, about 10,000 candle-power, was switched on. The question was whether the electricity used for that lamp should be charged for at the power rate or at the lighting rate. The power rate was 2d. per unit and the lighting rate 8d. per unit. If defendants were only liable for the power rate, then they were not liable for the balance, and £48 5s. 10d. was enough. If defendants were liable to pay at the lighting rate, then plaintiffs were right. There was no dispute as to the figures. The judge had found that plaintiffs were entitled to charge at the lighting rate. He said that was wrong. There was a separate meter for this light. There was no statutory distinction between current supplied for power and lighting purposes. It was a distinction introduced by the supply authorities themselves for their own commercial purposes. They quoted a lower rate for power purposes to induce people to take electricity during the daytime. Plaintiffs were entitled to charge 8d. unless defendants could protect themselves by Sections 19 and 20 of the Electric Power Construction Act of 1882. His case was that this particular supply was being used by defendants for power purposes, that the plaintiffs' system was to supply their consumers generally for power purposes at 2d. a unit, and that defendants were, by Section 19, entitled to be supplied at 2d. a unit. The judge had found on the facts that defendants' supply was a power supply, but that, nevertheless, plaintiffs were entitled to charge at more than their advertised power rate. Power supply was defined by the suppliers as electricity used directly or indirectly for purposes other than lighting.

Mr. Justice Eve: That is exactly what you do use it for. You light your lamp for the moment of time when you are taking somebody's more or less engaging face.

Mr. Blanco White said the judge had found that defendants were using it for power. A distinction had to be drawn between light and electricity used for the purposes of lighting. Electricity could make light in many ways, even when it was not used for the purpose of lighting. It might be used for medical or for heating purposes. Here his case was that it was not used for the purpose of lighting. This arc lamp was on a separate circuit from the ordinary lighting lamps. It was of no use for lighting purposes owing to its intense glare. It was used for the purpose of effecting a chemical change in the photo-plates. It was not used for lighting, though, incidentally, it gave out light.

He referred to the agreements between the parties, and Lord Justice Bankes remarked that in the agreemente this arc lamp seemed to have been treated as a special form of power. The judge had found that was so and that the plaintiffs were entitled to do so provided they treated all photographers alike.

Mr. Blanco White submitted that was wrong in law.

Lord Justice Bankes said the plaintiffs had got a free hand to charge what they liked within the maximum, and it was for the defendants to show that plaintiffs were not entitled to treat this as a special class of power user.

Mr. Blanco White explained that a special arrangement was made in October, 1921, by which since that date defendants and other professional photographers in the area were charged 4d. a unit for these arc lamps. Plaintiffs' contention was that the consumption did not warrant a supply being given at other than the lighting rate. Plaintiffs had not given any evidence differentiating photographers from other persons who used power intermittently during the daytime.

Without calling on the other side the Court gave judgment.

Lord Justice Bankes said this was an appeal from a decision of Mr. Justice Swift, which appeared to him to be quite right. The claim was by the plaintiffs for charges for electricity supplied to the defendants for a certain period, and over that portion of their supply which was used in the defendants' photographic arc lamp this dispute arose, defendants contending that they had been overcharged in respect of that portion of the supply. It was not disputed that as a matter of practice plaintiffs and other supply companies did make a difference in the prices they charged between a supply for lighting purposes and current supplied for power purposes, but they were entitled under their statutory powers to charge for both classes up to whatever their maximum charge might be. The statute of 1882 contained provisions against granting one customer a preference over another customer, and the case for the defendants here rested on the contention that the plaintiff company had not brought themselves within the protection, if he might so express it, of Section 19 of the Act, which provided that where a supply of electricity was provided in any part of an area for private purposes every company or person within that part of the area should, on application, be entitled to a supply on the same terms on which any other company or person in such part of the area was entitled under similar circumstances to a corresponding supply. Now the case for the defendants was this: that this current was in fact supplied for power purposes. That was so found by the judge, and in his opinion was rightly found, having regard to the definition of power purposes. They said, however, that plaintiffs were overcharging them because they were charging 4d. a unit, whereas plaintiffs charged their other customers who were not photographers for power within their district 2d. a unit, and plaintiffs could not justify that. The answer of the Electric Company was this: It is true we do charge you and all other photographers who take current for these arc lamps a charge in excess of what we are charging other customers for power, but we say we are justified because in the language of the section the circumstances are not similar, and the supply is not a corresponding supply. This question as to the right of a supply company to make differential charges had been before the Court on several occasions. Mr. Justice Sargent's judgment in the Attorney-General *v.* Long Eaton Parish Council had been cited and relied on. Mr. Justice Sargent said: "Under each section of the Act of 1882 I think that the whole circumstances may be considered from the broadest possible point of view, and the question is whether the circumstances affecting customer A and customer B in relation to their supplies of power are substantially dissimilar or sufficiently dissimilar to justify broadly the differentiation proposed by the supply company." Applying that test to this case, customers A were photographers and customers B were all other customers in the district who received power at the power rate, and the question was whether it was sufficiently established here, taking what the judge described as the broadest point of view of the position, that the circumstances in which the photographers were taking current for these arc lights were substantially dissimilar to justify the differentiation. It was true no evidence was given in reference to the particular length of use of the current for the arc lamps, but apparently the judge was allowed to use his own knowledge of these matters and his own common sense. These lights were of many thousand candle-power, and the Court were entitled, from their knowledge, to conclude that these arc lights were used at intervals only, depending on the number of customers and the number of photographs taken. Secondly, when they were, in fact, used it was only for a short period of time. In these circumstances, was the judge entitled to come to the conclusion that the circumstances as between these two kinds of customers were circumstances substantially dissimilar? He thought the judge was right, and he thought the defendants had failed to establish that the charge which plaintiffs sought to make was an overcharge. The appeal must therefore be dismissed, with costs.

The other judges concurred.

BURGLARY AT A STUDIO.—A burglar had a busy time in Knightsbridge last Friday. Four shops were broken into, including the premises of H. Walter Barnett & Co., photographers, where two cameras were stolen. The burglar was captured.

Photo-Mechanical Notes.

Election Posters.

THE approaching election affords the lithographer an opportunity to specialise in the rapid and cheap reproduction of enlarged poster photographs of the various candidates.

The method used must be one that lends itself to quick reproduction, and for this purpose the Bromoil transfer method, or the making of an enlarged negative on bromide paper, and from this printing on the sensitised zinc, is particularly suitable.

Working by enlarged paper negative is as follows:—A small screen negative is made from the original photograph. The screen selected will depend upon the enlargement required.

Screen.	Enlargement.	Reproduction.
60	2	30 lines to each.
60	4	15 lines to each.
120	8	15 lines to each.
120	12	10 lines to each.
150	3	30 lines to each.
150	5	30 lines to each.

The dot effect disappears for the normal individual.

10 lines to inch, 25 feet away
15 lines to inch, 15 feet away.
30 lines to inch, 8 feet away
50 lines to inch, 5 feet away.

The high-light dots should not be as closed up as is usual for ordinary direct photo-litho, and the shadow dots should be somewhat larger. The screen negative is enlarged upon a contrasty bromide paper, having a thin paper support, or upon "Transfero type" contrasty paper; if the latter paper is used the gelatine film containing the silver emulsion can be transferred to glass, and then reduced or intensified if necessary. Paper negatives should be correctly exposed and then well developed in a non-stain developer, as directed below. When dry, the paper negative can be made translucent by applying the following mixture to the paper side of the print:—

Castor oil, 4 ozs.
Ether, 1 oz.

The negative, when ready, is placed face down on the sensitised zinc and exposure made to a strong light in a vacuum printing frame. Exposure is about 6 times as long as for an ordinary glass negative. Any type-matter required can be set up and an impression taken on transfer paper and transferred to the zinc-plate, or this can be drawn or written on white Bristol board, and the portrait stuck in the required position, when it can be obtained on the negative. If the type-matter is drawn in a good black ink in which is mixed a little gamboge it will be an easy matter to prevent the dot effect forming, so that it will print solid.

The production of the Bromoil transfers is as follows:—

The screen negative is enlarged on a glossy contrasty bromide paper and then well developed in one of the following developers, Glycin for preference:—

Glycin.

Water	10 ozs.
Soda sulphite	250 grs.
Potass carbonate	500 grs.
Glycin	100 grs.
Potass bromide	3 grs.

Metol-Hydroquinone.

Water	10 ozs.
Metol	20 grs.
Soda sulphite	360 grs.
Potass carbonate	120 grs.
Hydroquinone	30 grs.
Potass bromide	20 grs.

Only correctly exposed and well-developed prints will ink up properly. After development the paper is thoroughly washed, but not fixed at this stage. The developer must be washed out before applying the bleaching solution, which is made as follows:—

A.—Chromic acid (pure), 10 per cent. solution.
B.—Copper sulphate, 200 grs.
Common salt, 2 ozs.
Water, 10 ozs.

For use take of A—½ oz.
B—10 ozs.
Water—20 ozs.

The temperature of this solution should be 65—70 Fahr. At this temperature bleaching will take about 10 minutes. After bleaching the print is well washed and then placed in the following bath for 5 minutes:—

Hypo	6 ozs.
Metabisulphite of potash	½ oz.
Water	40 ozs.

The temperature of the bath should not be below 60 deg. Fahr. Again wash the print and dab moisture off with blotting paper and then with a chamois leather. The print can then be placed in methylated spirits for about 2 minutes, and then hung up for 5 minutes, when it should be ready to receive the transfer ink which is stone to stone retransfer ink, let down with a small quantity of mid litho varnish and a few drops of oil of spike, lavender and rectified turps. If the transfer is allowed to dry the ink can be applied by a roller until a thin grey coating of ink is obtained. The print is developed by soaking in slightly warm water for 10 minutes, and then removing it from the unexposed portion by gently rubbing with a swab of cotton wool. The transfer, when complete, is transferred to zinc by the usual method. Bromoil transfers can be rolled up 5 or 6 times provided the gelatine will still hold to the paper support. After the first transfer has been taken the surface should be carefully cleaned with solvent naphtha, and when the naphtha has evaporated some of the following solution can be applied to the surface and then dabbed off with fluffless blotting paper:—

10 per cent. ammonia	1 oz.
Glycerine	3 ozs.
Water	10 ozs.

Inking up can then be carried out, X-Tone.

The following patents have been applied for:—

BAS RELIEFS. No. 27,936. Photo-mechanical process for producing bas-reliefs. Mauseath Photo Sculpture, Ltd.

PRINTING BLOCKS. No. 27,293. Process of producing photo-mechanical printing blocks. A. Galetzka and O. Richter.

TRANSFER METHOD. No. 29,126. Transferring images on to zinc, etc., plates for printing. C. H. Stringer.

Exhibitions.

BRITISH LANDSCAPE PRINTS.

AN exhibition of landscape work that shows us, as a nation, where we are is just what was wanted. The Affiliated Societies of Great Britain have evidently felt that as landscape is the national art, landscape should be encouraged in amateur photography; and so for the month of November the Royal Photographic Society is covering its walls at 35, Russell Square, that all may see what can be done by the real amateur who does not want to become a professional portraitist, and who is anxious to try his skill against all the talented American and Colonial landscapists who usually grace our shows. The idea is creditable, and the results are quite reassuring.

As far as my recollection goes, this exhibition is the first of its kind and if it were possible to remember any show of recent years and consider it on its landscape merits alone, this would probably be found to excel. Yet one of our most talented landscapists does not send Mr. Betram Cox. The honours are perhaps carried off by Mr. Charles Job, whose fine work scores because there is more of it than there is of any other individual. His best picture to my mind, is "An Old Bridge, Pulborough" (8). It looks something like a "Liber" print of Turner's, so beautifully designed and in good keeping is it. It has merits at all points and of common distinction in photography. The sky, the river, the bridge, the quiet effect, the general strength and mastery all go to make this work a camera classic.

Landscape has moved on surely but slowly. It has wisely been content to step in the footprints of the painters, recognising, perhaps, that the aim is no longer primarily to make a good photograph, but to make a good picture. Some men are treading pretty closely in the old footprints; for example, H. van Wadenoyen, junr., whose "Sand, Sea and Sky" (58), with its extreme gradation of sky and low horizon, is about as close a copy of a water-colour by D. Murray Smith as could be achieved by photography.

What is most striking, however, to those who knew the photographs of the long past is the wider, more exalted, vision, which

seeks less to give the concrete facts by a righteous and meticulous technique than to give the abstract, the illusive, by any and all means. Sometimes this is offered in spite of the incidental misfortunes of composition, as in Fred Judge's exquisite effect of light on a ploughed field, which, in "The Choked Plough," finishes at a horizontal line against the sky dividing the print into halves like a domino. It is better to have the light and quality at this cost than not to have it at all.

Such works are, however, but a symptom of the new vision. The feeling for orderly and well-balanced composition is equally characteristic. "The Straw Stack," by T. H. B. Scott, is a noble design, and so is his "Summer." A very notable work combining happy design and an intense feeling for quality is H. van Wadenoyen's "Houses at Cowbridge," which with its single vertical plane and its lack of distance is scarcely a landscape at all in the narrow sense of the term, and yet the qualities it possesses should be, and are, the objectives of all who produce landscape in the true spirit.

The romance of the weather, as well as the literary romance, is likewise a characteristic of modern British camera work. Foreign countries, for the most part, may enjoy more sunshine, but they certainly experience less variety than we do in these islands, and that change of mood in Nature is the photographer's salvation. It gives him a thousand dramatic skies for one in other lands; it shows him the soft cloud shadows chasing each other over hill and plain; it secures for him the diffusion of light instead of a merciless directness of the sun's rays; it brings mist and vapour to soften hard edges and notes, and to wrap everything together in harmony. It has always done these things, but the photographer has been ignorant of the fact until recent years, and this show, with its exemplars of all these conditions, is a veritable manifesto of British photographers. Nothing else has so distinctly marked a stage in the gradual development of the new vision from the old.—F. C. Tilney.

FORTHCOMING EXHIBITIONS.

November 4 to 11.—Bournemouth Camera Club. Particulars from the Hon. Secretary, 88, Old Christchurch Road, Bournemouth.

December 9 to 31.—Rochdale Amateur Photographic Society. Particulars from the Hon. Secretary, W. Lord, 10, Derwent Street, Rochdale.

1923.

February 5 to March 3.—Northern Photographic Exhibition, City Art Gallery, Manchester. Latest date for entries, January 12. Particulars from the Hon. Exhibition Secretary, Walter Johnson, 30, Hartington Road, Chorlton-cum-Hardy, Manchester.

March 1 to 8.—Birmingham Photographic Society. Latest date for entries, February 15. Particulars from the Hon. Secretary, J. E. Breeze, 178, Broad Street, Birmingham.

March 2 to 31.—Pittsburgh Salon of Photography. Latest date, February 5. Secretary, Charles K. Archer, 1,412, Carnegie Building, Pittsburgh, Pa., U.S.A.

March 13 to 16.—Exeter and West of England Photographic Exhibition. Particulars from the Hon. Secretary, Frederic G. Tutton, 9, Union Road, Pennsylvania, Exeter.

March 15 to 24.—Photographic Fair, Holland Park Hall. Secretary, Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

Leyland Motor Photographs.—Prizes have been awarded by Messrs. Leyland Motors, Ltd., in the last quarterly competition for photographs of Leyland vehicles. As manufacturers of motor lorries, a de luxe tourist chassis, and, recently, the remarkable little "Trojan" car selling at £175, the Leyland Company have long appreciated the value of photographs as part of their sales organisation. The prize-winners are as follows:—1st, H. Lunn, Slaithwaite (£3 3s.); 2nd, Eric Guy, Basingstoke (£2 2s.); 3rd, W. Andrews, Norwich (10s. 6d.); 4th, W. S. Trapp, Southport (10s. 6d.); 5th, W. H. Counsell, Rishton (10s. 6d.). Consolation prizes of 5s. were also awarded to:—W. H. Topham, Grimsby; F. Marshall, Birmingham; S. Goldsack, Chatham; H. H. Cooper, Bridgeport; W. H. Mitchell, St. Helens; G. E. Swann, Keighley; J. W. May, Sheffield; W. Bretherton, Leyland; H. Godwin, Southboro'. The competition is being continued during the present quarter, the closing date being December 30. Particulars from the Company at Leyland, Lancs.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, October 23 to 28.

Cameras.—Nos. 29,418 and 29,419. Folding cameras. Baille-Lemaire et Fils.

Enlarging.—No. 29,037. Photographic enlarging apparatus. A. C. W. Aldis.

Focussing Devices.—No. 29,420. Focussing devices for cameras. Baille-Lemaire et Fils.

Photographic Mediums.—No. 28,821. Photographic mediums. Wadsworth Watch Case Co.

Printing Frames.—No. 28,850. Photographic printing frames. F. Taylor.

Sensitised Papers.—No. 29,053. Sensitised papers. Hydroloid, Ltd. (Exportingenieure für Papier und Zellstofftechnik Ges.).

Cinematography.—No. 28,825. Cinematograph, etc., screen. C. A. Clark.

Cinematography.—No. 29,348. Production of cinematograph films and cameras therefor. C. A. Lowe.

Colour Cinematography.—No. 28,902. Two-colour cinematography. Cinechrome Instruments, Ltd., and S. J. Cox.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

Lantern Screens.—Non. 166,133. (July 9, 1920.) The screen consists of a sheet of plate-glass having a "satiny sheeny" surface A continuous succession of approximately equal rounded off projections are made on the surface. Such formations, being of minute and regular character, are almost invisible to the naked eye. The back of the screen may also be silvered. The glass plate may be covered with a series of flutes, prisms, ridges, grooves, or corrugations. The satiny sheeny surface is produced by first heavily etching with "white acid" or sand-blasting, and subsequently reducing or cleaning with hydrofluoric acid. The screens are of great efficiency, and permit of the entirely satisfactory viewing, in full indoor daylight, or in the presence of bright artificial light, of cinematographic or other pictures. It will also permit of the projection in darkness of pictures of entirely satisfactory brilliance, but with much less expenditure of light power than is necessary under the usual screen conditions. The amount of heat generated in the operating box and the cost of projection is thus reduced. A surface optically equivalent to the "satin-surface" obtained by acid etching may be made by sandblasting or grinding and subsequently "reducing" or "clearing" very fully with hydrofluoric acid, so that the original great diffusivity of the frosted surface is very markedly reduced.

In the case of a surface provided with flutes, prisms, ridges, grooves, or corrugations, these are arranged vertically from top to bottom, either on the back (with a view to the prevention of the lodgment of dust), or on the front of the "screen," or in some cases on each surface. Such corrugations ensure a considerable expansion of the lateral limits within which the image formed on such "screen" may be viewed efficiently.

The first illustrative embodiment of the invention takes the form of a "screen" adapted for the display of lantern, cinema or other pictures. It consists of a sheet of plate-glass the back surface of which is prepared in accordance with the "satin-surface" or its optical equivalent, and is silvered and backed as is usual in the manufacture of glass mirrors. As a modification of this, the front surface (which is unsilvered) also is prepared with "satin-surface" the reflection mirror-wise of the projecting lantern by such surface being thereby prevented.—Percy Edward Correll, Verco Building, North Terrace, Adelaide, South Australia.

The following complete specifications are open to public inspection before acceptance :—

DEVELOPING TANK.—No. 187,228. Photographic developing tank. A. Waterworth.

SHUTTER.—No. 187,242. Photographic shutter with movable screen. Compagnie Aerienne Francaise.

New Materials.

Materials for Embossed Photographs. Made by Bardilis, 75, Gt, Titchfield Street, London, W.1.

THE production of photographs, especially portraits, in embossed relief interested photographers now and again years ago, but the absence of a simple yet effective process has prevented many from attempting the work. The "Releefoto" process therefore invites favourable comment, since it provides a method which may be easily operated without previous experience and with a complete absence of apparatus. The previous methods of obtaining embossed photographs have required some type of press, but in this system the relief is obtained simply by spreading on the print a preparation which, when dry, expands the paper. The resulting embossed prints are very attractive in appearance; a few specimens shown in a photographer's window can hardly fail in attracting attention by their novelty and distinctive quality.

A photograph, preferably on a collodion self-toning paper, is taken, and upon the back a rough outline of the part which is to be embossed is made with a blacklead pencil. The print is then coated within this outline with a substance supplied by the makers, which has the name of "Releefoto." It is a thick, jelly-like preparation, strongly smelling of amyl acetate, and it is applied in a novel manner. In the set of materials are included a number of small cones, strongly made of glucose paper. One of these is partly filled with the preparation, and the end folded over. The apex of the cone is then cut off, and the "Releefoto" may be pressed out through the small orifice thus made. This is applied carefully to the portion marked on the print, and, when completed, the print is hung up to dry. When quite dry, and this takes some hours, the portion coated with the preparation will be found to have considerable relief, and the print may then be mounted in the usual manner. We have tested the process and find it extremely simple to work. Quite good results, showing considerable relief, are obtained with astonishing ease. The necessary materials are supplied in two sets. Set No. 1, containing a tube of "Releefoto," mounting boards, and glucose paper cones, together with a print suitable for embossing, retails at 5s. 6d. Outfit No. 2 contains, in addition to larger quantities of the above materials, a packet of printing paper, tube of mountant, and four bottles of tinting solutions with the necessary brush. This outfit retails at 10s. 6d. Full directions for working the process are included in each set.

TRANSPARENT TISSUES.—The Vanguard Manufacturing Co., Maidenhead, send us specimens of the new thin transparent tissues which they are supplying for the insertion of titles into negatives, autograph greetings, and similar additions to prints without the added labour of a further printing. Any inscription is written with a fine pen on the tissue, using the ordinary "Photopake" of the Vanguard Company. The tissues take this preparation exceedingly well, so that the finest writing or tracing which is ordinarily required can be very readily done. The tissue is of extreme thinness, as thin as tissue paper, yet perfectly transparent and flexible and free from any visible structure. Apparently it is not a manufacture from celluloid, since, on applying a match, it burns with very much less flame than a piece of newspaper. We are quite sure that the tissues will find many uses in every studio establishment. They are supplied in half-plate or 7 x 5 size, price 1s. per packet of 18 sheets. A shilling packet of 36 sheets of quarter-plate size is also sold.

CHRISTMAS MOUNTS.—Messrs. W. Butcher & Sons, Ltd., Camera House, Farringdon Avenue, London, E.C.4, are supplying a selection of artistic calendar and passe-partout mounts for the Christmas trade. Series 6281 and 6291 are attractive calendars, and are made in four sizes suitable for C.D.V., ½-plate, Ia F.P.K., and postcard prints, either upright or oblong. No. 6281 is made of matt white card with deckle edge, and an overlay of linen faced board or black linen faced card; while No. 6291 is of black or brown card overlaid in matt white or fawn. These mounts, which are suitable for any type of print, are illustrated below.

In passe-partout mounts, the "Kwick" mount greeting card is extremely well made, and is supplied in either brown or grey. The introduction of a personal note has been provided for in the "Artist" series of passe-partout mounts, in that a small card

bearing the signature of the sender may be inserted to cover an opening before attaching the back. Five sizes, with various greetings, are available in this series, ranging from V.P.K. to postcard. Particulars of these mounts are contained in the booklet "Photography in the Home," which may be obtained from Messrs. Butcher upon application.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SUNDAY, NOVEMBER 12.

United Stereoscopic Soc. "Isle of Purbeck." G. E. W. Herbert.

MONDAY, NOVEMBER 13.

Birmingham Phot. Art Club. Extraordinary General Meeting.

SATURDAY, NOVEMBER 18.

Borough Polytechnic Phot. Soc. Dance in Edric Hall.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, November 7.

The occasion being the delivery of the President's address, Mr. Wastell vacated the chair in favour of Mr. Dudley Johnston.

Mr. Wastell took as his subject the evolution of the lantern slide, and followed a disappointingly brief discourse by a large display on the screen of transparencies, illustrating the development of the lantern-slide from pre-photographic days to the present time. However, his many humorous comments on these latter were a compensation for the brevity of his more formal address.

The origin of the lantern slide could, perhaps, be traced, said Mr. Wastell, to the period of John Baptiste de la Porta, who, when he was only 16 or 17 years of age, wrote a book describing the use of a convex lens in the camera obscura. He was thus able to draw on a transparent material designs, views, etc., which were projected by the lens, and these may have been used for further examination by transmitted light. These were termed magic pictures, and possibly the term magic lantern arose from this description. Séances were given in about the year 1570, in which various objects were shown in a darkened room, but Mr. Wastell was of opinion these effects may have been exhibited by means of a concave mirror. The first slides, or sliders as they were called by some writers, were prepared by hand drawing upon glass, and were very crude, but it was about the year 1844, when moving coloured slides and chromotropes were first shown. In 1846 it was customary to use two lanterns for showing the slides, the work being so far advanced that dissolving views were possible. At the old Regent Street Polytechnic, around about the year 1891, Lewis Wright's method of optical projection was in use. Some marvellous effects were here produced, as many as six lanterns being used at one period. The dissolving effects were cleverly managed, said Mr. Wastell, and in a lurid description he explained how the whole range of seasons of the year were given with one landscape view. Noise effects, such as rain, thunder, etc., were produced by an extra operator shaking a sheet of metal or dropping barley into a hollow vessel. The first whispers of photographic slides were heard about the middle of the nineteenth century, the albumen silver process of Niepce de St. Victor, in 1847, and the wet collodion of Scott-Archer, 1851, making possible the utilisation of these processes for transparent positives. In 1853 Mr. J. B. Dancer showed some specimens of micro-photographs, an account of which appeared in the "Manchester Guardian" of that date, and these, said the lecturer, could be no other than photographic transparencies. "Chambers' Journal," in 1859, reported the fact that pictures 20 ft. in diameter were being shown to hundreds of people, and in 1860 the photographic lantern slide appeared to be fully established. An interesting reference was made by Mr. Wastell to the stereo-transparency lantern of Thos. Sutton. In the early part of 1856 this worker showed stereoscopic slides by the aid of two lanterns, the spectators being given special spectacles with which they were able to view the scenes projected upon the screen in some manner of relief. About 1856 the stereo transparencies of Messrs. Ferrier & Soulier were much in evidence, and it was suggested that the present size of the lantern slide originated from these. The stereoscopic slides consisted of two pictures, each 3¼ in. square, and possibly workers in those days found an easy method of making transparencies for lantern projection by printing single pictures upon glass from the stereo negatives.

The hand-made slides were of all sizes, those in use at the Polytechnic were, in the early days, about 8 in. by 5 in. An amusing account of a suggestion in 1857 to throw the projected image upon a cloud of vapour or upon smoke drew from the lecturer, a further suggestion that this method would be useful to travellers or explorers, and would enable them to scare the native population by night. The albumen process seemed to be extensively used, said Mr. Wastell, about 1857, and possibly was more popular, when such substances as India pale ale, coffee, tea, raspberry vinegar, and oxymel, were used as preservatives. The first commercial manufacturers of lantern slides in this country were, said the lecturer, Messrs. Negretti & Zambra, their slides being particularly of geographical or architectural interest.

At the conclusion of his address Mr. Wastell proceeded to show upon the screen many interesting examples of early coloured slides. Commencing first with mechanical slides in wooden frames, he said that it was necessary for an expert to operate them. The slowly-turning windmill and the "man eating rats" called forth loud applause. The "tiger and the tub," a relic of one's childhood days, recalled many happy memories of Christmas parties, while the skipping slides and the "growing nose" of "Ally Sloper" produced much amusement. Some of the older hand-coloured slides, using transparent oil colours, were very beautiful, the colours much resembling old stained glass. The photographic slides shown by Mr. Wastell included the products of many expert workers of to-day, one slide in particular of an extremely delicate nature, the work of Mr. J. Dudley Johnston, being much admired. Only one of the lecturer's own slides was shown, this being by the transferotype process. In conclusion, Mr. Wastell said that the latest advances in lantern slide making and projection were shown in the cinematograph film. These were merely a large number of single slides shown in rapid succession, and the latest colour processes, including Kodachrome and Prizma, demonstrated the great advances which had been made in this branch of photography.

On the proposition of Dr. Rodman, seconded by Mr. T. H. B. Scott, the hearty thanks of the meeting were accorded to the president, who, in reply, said he would also like to thank the many friends who had helped him by lending specimens.

CROYDON CAMERA CLUB.

The seating capacity of the not too vast club room was taxed to its uttermost, as Dr. C. Atkin Swan was billed to appear. An unkind fate, doubtless assisted by the weather, ruled otherwise, and all heard with much regret that Dr. Swan was confined to bed. The Secretary was also absent with a de luxe cold, and a visit to the dentist placed restrictions on the President's usual flow of speech.

With disaster in the offing, the Club is always seen at its best, and Mr. F. Ackroyd, at a few minutes' notice stepped gallantly into the breach with a really interesting narrative of a second holiday trip into Germany. In common with other Britishers, he experienced nothing but consideration and courtesy, with the possible exception of the presentation by projection of the core of an apple by a small German boy. On another occasion justifiable indignation was engendered by the action of two well-dressed ladies, who had the bad taste to apply force to Mr. Ackroyd's person from behind, in an abortive attempt to curtail a conversation with a puzzled railway booking clerk. Sad to relate, they transpired to be of a pushful English-speaking nation.

Alluding to the occupied territory, the employment of swaggering black troops by the French certainly stuck in the throat. More cheering was an account of how it felt to be a millionaire for a few weeks, and among many other side-lights one learnt without surprise that the income of a German professor often was lower than that of a street sweeper.

The discussion was earnest in tone and candid, for the audience included some who had been in the retreat from Mons, and, in the full meaning of the word, suffered captivity in Germany. It is old and painful ground, which need not again be traversed, for the facts will be remembered, excepting always by those who prefer to stultify memory for the sake of a presumed good intention in the future. Only need it be mentioned that Mr. W. E. Dunmore, who had popped over from Paris, expressed consternation at seeing no blackboard and chalk, and Mr. Tompkins, who had shot up from New Zealand, strikingly conveyed a note of active brotherhood from across the seas, not necessarily based on humanity, but rather on pride of race.

Of a certain generous and anonymous donor—anon.

THE LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.—After an absence of several years Mr. Geo. A. Booth, F.Z.S., reappeared at Liverpool on November 2, with his lecture, "Nature Study with a Camera." Mr. Booth showed a large number of slides illustrating birds, animals, insects, etc., in their native haunts, and his illustrations were not merely very fine specimens of nature studies; they were also, in the main, admirable examples of lantern-slide work.

In his introduction Mr. Booth put in a strong plea for the use of the camera by the Natural History student on two grounds. A characteristic photograph of a living animal in its native environment is of higher and more permanent value than a poor specimen, badly preserved and mounted. Secondly, and of greater importance to all lovers of nature, the ruthless collecting of specimens had already resulted in the extinction of species at such a pace that the present rapid growth of nature study with its thousands of new collectors appearing each season, each intent on his own collection, threatened to reduce the scope of future study. Thus the camera may play a large part in the preservation of rare forms of life if students will be satisfied by the photograph album instead of the glass case.

The lecturer made the claim for his special branch of work that interest in nature photography grows steadily upon the worker as the years pass owing to the inexhaustibility of the extent, and the charm of the work, whereas every other branch of photography, whether portraiture, landscape, etc.—and he had essayed all—sooner or later loses its hold on the photographer, however keen a starter he may have been.

Dr. B. T. J. Glover, in moving a vote of thanks to the lecturer, expressed the feeling of the audience when he paid a tribute to the wonderful patience and technical skill, two very necessary qualities for the production of work of such high quality as had been shown that night, which had been so clearly demonstrated by the slides projected on to the screen.

Commercial & Legal Intelligence.

NEW COMPANIES.

READ'S PHARMACY, LTD.—This private company was registered on October 3, with a capital of £400 in £1 shares. Objects: To carry on the business of dealers in photographic materials, scientific instruments, etc. The first directors are: A. E. Read, 21, Magdalen Road, Norwich, photographer and dealer in scientific apparatus (permanent governing director); Mrs. F. C. R. Read, 21, Magdalen Road, Norwich; C. I. Burns, 213, College Road, Norwich. Qualification of governing director, 200 shares; of other directors, £10. Registered office: 21, Magdalen Road, Norwich.

APEM, LTD.—This private company was registered on October 25 with a capital of £100 in £1 shares (50 pref. and 50 ord.). Objects: To carry on the business of manufacturers, exporters and importers of and dealers in photographic cameras, plates, films, papers, mounts and frames, optical lenses, prisms, binoculars and optical glass, etc. The subscribers (each with one share) are: W. Piper, 38, Alexandra Road, Croydon, secretary; H. H. Law, "Starbrick," Birkbeck Road, Mill Hill, N.W.7, sales manager.

The subscribers are to appoint the first directors. Qualification £1. Remuneration as fixed by the company. Secretary: W. Piper. Registered office: 3, Soho Square, W.1.

MR. SOLOMON J. SOLOMON PAINTS FROM PHOTOGRAPHS.—Mr. Solomon J. Solomon, the well-known R.A., has just completed the great picture of the Coronation luncheon held over eleven years ago. Sir John Bacon, who started the painting, died some time ago, and Mr. Solomon was asked to finish it. The "Daily Graphic," giving an account of the painting, says: "He (Mr. Solomon) was not at the luncheon. So, doing the best he could, he borrowed all sorts of photographs from the "Daily Graphic," visited the Guildhall several times, and started a work which will become historic. For nearly three years, at odd times, he went on painting it. But, since many of the diplomatic personages in the picture were unknown to him, he took all sorts of opportunities of attending social functions, where they were present, to obtain their likenesses." Obviously, ten year-old portraits were the most helpful.

News and Notes.

WAR FILMS.—According to the "Daily Mail," seven hundred thousand feet of films, illustrating war subjects, and weighing about two tons, are being stored in protected vaults in the basements of the War Office.

CAMERA HOUSE JOURNAL.—The November issue of Messrs. Butcher's house organ contains particulars of goods specially produced for the winter trade. Passe-partout binding, retouching and tinting outfits, the Aldis-Butcher projection lantern, and special bargains in daylight enlargers are attractive items. A dissolved acetylene outfit should prove a useful adjunct to the travelling lecturer.

ROYAL PHOTOGRAPHIC SOCIETY.—The meeting which is to be held at 35, Russell Square, W.C.1, on Tuesday next, November 14, 1922, will be under the control of the Scientific and Technical Group of the Society. Three papers will be read: 1. Experiments on the tensile strength of gelatine and gelatine-jelly; discussion of the results as bearing on the structure of gelatine; with a note on the evolution of heat by gelatine when expanding in water, by James C. Kingdon. 2. Rapid sulphiding of bromide prints. Toning with gases instead of liquids, and demonstration of methods employed. By K. C. D. Hickman. 3. Photo-micrographs in colour, mounted to exhibit changing tints, by D. Northall-Laurie.

A "PHOTOGRAPH OF PETS" COMPETITION.—The "Weekly Dispatch" has started a new photographic competition of interest to professional workers. Cash prizes of over £500 are given for photographs of "You and Your Pet." The competition will run for sixteen weeks, and each week for the best photographs submitted there will be awarded: 1st prize, £5 5s.; 2nd, £3 3s.; 3rd, £2 2s.; with twelve consolation prizes of 10s. 6d. and a prize of £1 1s. to the photographer whose picture is awarded the weekly first prize. At the end of the competition there will be for the best photographs submitted during the competition final awards of: First prize, £100; second prize, £25; third prize, £10. A prize of £5 will be awarded to the photographer whose picture receives the £100 prize. Photographers' special show cards for window display may be obtained free from the "Weekly Dispatch," Carmelite House, London, E.C.4.

PRINTS IN PASTELS.—The name of Dr. Joseph Sury, of Wynghene, Belgium, has cropped up from time to time in photographic literature in connection with the invention of a printing process by which prints in any colour or in several colours may be very readily made. Within the last few days we have had the opportunity of seeing a considerable number of specimens of the process, both monochrome and multicolour, and have been exceedingly pleased with the freshness and vigour of the results. The process consists in sensitising a special paper with a solution containing ammonium bichromate, chrome alum and alcohol. The sensitised paper is printed under an ordinary negative, developed in warm water, transferred to an avid bath, washed for two or three minutes and then hung up to dry. At this stage the image is invisible, and is "developed" by application of pastel colours in powder with a brush. Most striking broad effects are obtainable by the process. In the case of monochrome prints, the manipulation is exceedingly simple and rapid; multicolour effects naturally call for the skill and judgment of an artist. The paper for the process is supplied by Dr. Sury, who may be addressed in this country, c/o Mr. H. Vendelmans, 59, Highbury Park, London, N.5.

PHOTOGRAPHS IN CAMEO RELIEF.—Since mentioning a week or two ago to a correspondent that we knew of no source of supply of photographs in relief, we have had an opportunity of seeing the work of this kind which is being done by Mr. W. A. Whiting, of 51, Eden Street, Kingston-on-Thames, a photographer and artist of many years of experience. Mr. Whiting has invented a process by which, from two portrait prints, he is able to make a cameo relief, in which the likeness is preserved with very great fidelity. The process is applicable only to profile portraits, which may be of any size. Mr. Whiting makes his reliefs of an average size (including bust) of from 2½ to 3 inches, and, in most of the examples which he has shown us, produces the cameo portraits in white on a blue ground, in the style of the jasper reliefs made years ago by the famous firm of Wedgwood. There are, no doubt, many people who would value a photographic reproduction in this relief form. As an inducement for photographers to bring the style before the notice of their customers, Mr. Whiting is prepared to supply one of the reliefs at the charge of 15s., 10s. of

which amount will be refunded on receipt of the first order; that is to say, a specimen of the process will cost a photographer only 5s. after he has placed his first order. The inclusive charge for one of the cameos, mounted in a suitable frame, is £2 2s.

Correspondence.

*** *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

*** *We do not undertake responsibility for the opinions expressed by our correspondents.*

BACKGROUNDS IN PORTRAITURE.

To the Editors.

Gentlemen,—In common with many professional photographers, I feel grateful for the excellent series of articles now appearing in "The British Journal of Photography," "With a Portraitist in the Studio," and for the assistance given by Mr. J. Effel in reviewing the principles of successful portraiture for his "poseur" brethren.

Having made this acknowledgment in full sincerity, your author will not feel hurt, I am sure, when I also voice my sympathy with him in his many unfortunate experiences with assistants, apprentices, and apparatus, but Chapter IX has given me the opportunity of repaying that debt of gratitude, already expressed, and of also earning a little on my own account from my fellow-craftsmen of both sexes.

One would gather from this article that the use of a scenic-effect background was sufficient in itself to condemn any artist of the camera. It may be true that many ludicrous examples of the use of such effects may be quoted. I myself have seen a photograph of a young man in evening dress, playing a violin in front of a splendid representation of an alpine scene; also a lady swimmer surrounded by trophies and dressed in regulation costume, "back-grounded" by an equally well-painted east-end view of a church with altar and choir stalls. Bad though these two examples are, I contend that they are not worse by one iota than the present tendency to "introduce the curtain" (I beg pardon, I should have written "oak panelling") on every occasion; nor would either of them be more out of place than that of "A Farmer with Dogs and Smock" before the oak panel.

"Oak panel," "sketch," "curtain," or any other style, followed with uninterrupted persistence, would certainly become monotonous, to say the least of it, and photographers would do well to spend a little time and thought, as well as some of the money now squandered on lens collecting, in securing a fair variety of scenic effects and the means of readily changing them as occasion demanded.

Like the camera art, mechanical skill has also advanced since the days of the "Frankenstein monster" and the "octagon," and I myself have seen an efficient and self-contained model with which twelve changes could be effected in one minute without fear of anything going wrong, and about which there are no uncertainties. I believe it will shortly be placed upon the market, though for the moment I am not in the position to give the name of the maker, and it has given me much surprise that your "Journal" has not contained full-page advertisements of this piece of apparatus.

Perhaps Mr. Effel will take up his "cue" and give a good demonstration of the "winning hazard," and thus fill the pocket of many underworked photographers, the "winning hazard," in my opinion, being adaptability of sitter and surroundings.—Yours faithfully,

B. Wheelwright.

173, St. Paul's Road,
West Smethwick, Staffs, November 6.

UNDER-EXPOSED PATCH ON NEGATIVE.

To the Editors.

Gentlemen,—In a reply given to a correspondent (on page 672), it is suggested that a fly on the light-filter may result in a portion of a negative being under-exposed. This suggestion reminds me of a very curious happening some time ago.

Frequently some of my negatives had large under-exposed patches of various shapes and sizes—always one patch, never more, on a negative. The defect occurred at intervals and worried me very much, and letters to plate-makers produced the usual crop of suggestions and remedies.

A careful watch proved that the defect always appeared when a "bulb" exposure of a second or less was given with a roller-blind shutter, and this gave a clue as to the cause. Further investigation proved that when a quick "bulb" exposure was given the tassel hanging at the end of the release cord jerked before the lens opening and so stopped the light—only temporarily, but long enough when a quick exposure was given to show itself upon the plate.

Releasiog the spring of the blind served to do away with the severe jerk (a high tension not being necessary for "bulb" exposures), and weighting the tassel made it doubly sure of hangihg down and not jumping in front of the lens during a brief exposure.

Shutters with tasselled cords are liable to act in this way, but when instantaneous exposures are given there is no jerking, and when long "bulb" exposures are given the jerking tassel is before the lens for too short a time to show on the negative.

This was an unlooked-for cause of trouble, and my experience may be of service to users of blind shutters for quick bulb exposures.—Yours faithfully,

E. Goddard.

THE SKETCH PORTRAIT.

To the Editors.

Gentlemen,—It was with the keenest pleasure that I read and digested the major portion of Mr. Effel's treatise on portraiture. It made one think that at last a man had arrived who would sweep away the silly and ignorant conventions of studio practice.

But alas, when I reached his remarks about white backgrounds, the bottom fell out of all the good I had already imbibed. How can such an unnatural accessory be reconciled with natural and artistic work? Did anyone ever see anyone else (except in a "sketch") floating in white space, denuded of background, foundation or surround? And when a half-tone vignetted frippery design is included on the white background it is infinitely worse from the view point of portraiture, though it might be all right as decorative work.

That white grounds have uses is true. They come in for such widely different specialties as theatrical studies (which are advertisements, not portraits) and machine photographs, but to hold up the taking of 20,000 consecutive portraits against one as an example to the Snappeshottes and Grousers, is inexplicable after reading Mr. Effel's earlier chapters. If he means it, well I fancy that many will stick to their flower pots, wooden rocks, unglazed windows and stormy seas (complete with bear-skin rug and marble pillar).—Yours sincerely,

J. R. Hall.

31, August Road, Liverpool.
November 6.

A DARK-ROOM LIGHT FOR BROMIDE PAPER.

To the Editors.

Gentlemen,—The letter from your correspondent "Hyperion" in your issue of the 27th ultimo, and the subsequent letters on the same subject in your issue of last week, raise a point which we think is worthy of further consideration. "Hyperion's" results, as suggested by Mr. Hall, may be due to the fact that he was using a red glass which passed some violet, but it is by no means impossible that his results were due to a property both of plates and bromide paper which is too little recognised.

As is suggested by "Hyperion," there is a definite red-sensitiveness of nearly all emulsions both plates and bromide paper, apart from such emulsions as have been specially colour sensitised. Although this red-sensitiveness is of no value in the normal use of the plate or paper, it is of very serious consequence when designing dark-room light-filters.

It was found, many years ago, when the subject of the construction of dark-room light-filters was taken up by us, that this red-sensitiveness varies considerably between different makes of plate and bromide paper, but that it is in all cases sufficient to make it an advantage to depress the red rather than the yellow-green in a light-filter intended for ordinary, non-colour-sensitised materials. Such a light-filter is still quite yellow in appearance. The Ilford "S" (for slow plates and bromide papers) and "F" (for fast plates) dark-room light-filters are, in fact, made in this way. It has not been definitely ascertained whether these emulsions have actually greater sensitiveness in the red than they have in, for example, the yellow-green, but even if this is not the case, the

very much greater luminosity value of the yellow green would easily account for the greater efficiency of light-filters constructed on these lines.—Yours faithfully,

ILFORD, LIMITED.

THE EFFECT OF DEVELOPMENT UPON GRAIN CLUMPS.

To the Editors.

Gentlemen,—In the "British Journal" of 1922, p. 443, Mr. F. C. Toy published some remarks concerning Silberstein's quantum theory of photographic exposure, and more especially Righter's and my own experimental investigations, criticising our results as based upon faulty interpretations and as experimental tests of the aforesaid theory.

In the first place, I should like to refer to a recent paper by Righter, Sheppard and Trivelli in the "Phot. Journ." (Vol. 62, 1922, p. 407), in which some of Mr. Toy's criticisms have been met in advance.

Slade and Higson (Proc. Roy. Soc., Vol. 98, 1920, pp. 104-170) rejected the development of clumps as units, basing this rejection upon the microscopic observation that on several occasions only one of two grains placed near to each other side by side or above each other developed while the other remained unaffected. On the other hand, we found that the reverse was generally true, and that the grains when clumped together act as one grain for development to the limit.

We had often observed cases where grains apparently in contact did not develop together, but in many of our emulsions these were few compared with those that developed in clumps. For instance, plates were prepared with our experimental emulsion W—12—C, in which the incomplete clump development, as mentioned by Slade and Higson, was almost entirely absent (type A, used for testing Silberstein's theory), and with the same emulsion, other plates showing strongly the incomplete clump development (type B). The different properties of these two types depend probably upon the cooling and other conditions of the coated emulsion. In both cases the grains in a clump were, all at the same time, sharply focussed in the microscope, with a magnification of 2,500. However, the single grains could all simultaneously be sharply focussed in the case A, but by no means so in the case B.

In both cases we are concerned with the dried emulsion layers after the development. The gelatine of the emulsion swells in the developer in a direction perpendicular to the plane of microscopic focussing. Therefore, even very small depth differences of the grains in the dry layer are enlarged in the developer, subsequent to coating, and it depends on this effect whether a grain will be found in a clump or not.

Now, some of our preliminary measurements have shown that the developed grain has a larger projected area than the intact grain. Thus, for instance, the projected area of some grains was found to be enlarged 1.2 times in a pyro developer. It was reasonable, therefore, to expect the existence of clump development. Actual displacement of a grain by reduced silver has thus far never been observed. It may perhaps be assumed that the thin gelatine layer surrounding each grain is penetrated by the silver, which is an easy matter in swollen gelatine, and which is also corroborated by the fact that every completely developed clump appears, even under the highest resolving power of the microscope, as *one* continuous mass of black silver.

The simultaneous focussing of all the grains of a clump cannot, therefore, be considered as the decisive proof that one has to do with a real clump, and not an apparent one. A discrimination between the two can be obtained only by a complete quantitative investigation of the behaviour of clumps (real or apparent) and of single grains in the developing process.

Mr. Toy has attempted to explain our curves from the standpoint of the development of single grains by means of probability considerations. With these, however, I am unable to agree. The clumps are not so regularly built up, that, for instance, at the development of a single grain out of a clump of six, the latter should be converted into a united clump of five grains. It would, in general, be split into two separate parts. The clumps show variety of configurations, and these latter influence the way a clump is split into parts. Thus, e.g., a chain of six grains, on losing one grain, may be converted into either

1 clump of 5 grains,
or 1 clump of 4 grains, and 1 single grain.
or 2 clumps, one of 3 and one of 2 grains.

From the standpoint of single grain development, it would be altogether impossible to construct with our data a clumping curve of the developed grains. The writer has tried to construct a clumping curve of the developed grains by means of the coating B, mentioned above, of which he has taken as many as 99 micrograms with over 11,700 measured and classified grains. As a result, while the single grains gave a smooth curve, it was utterly impossible to obtain any regularity with the clumps. On the other hand, Righter and Trivelli were unable to obtain smooth curves for the single grains from the data concerning the coating A, which behaved regularly with respect to the clumps.

It must be kept in mind that the clumping tendency is much stronger in the case of large flat grains than in the case of smaller and round ones, which among other things are prevented from coming into actual contact by the Brownian movement. The former case corresponds, of course, to plates and films of high sensitivity. Now, when a thin section is made of such a plate or film by means of a microtome and investigated microscopically, a very large number of developed clumps is found, sometimes of a prodigious size, and equivalent to an aggregate of a hundred or more grains. Is it possible to imagine that all these black clumps arose by each of their grains being affected by light, while of all the neighbouring single grains only a very small percentage was thus affected?

I am therefore of the opinion that although single grain development may take place where apparently contiguous grains exist, yet the development of clumps is also frequently shown by emulsions, and that in the plates which we used almost all contiguous grains developed in clumps. It would follow that conclusions as to the sensitiveness of the clumps would be valid for use in the testing of theories of exposure.

My thanks are due to Mr. Toy for his kindness in calling attention to this matter.—Very truly yours,

A. P. H. TRIVELLI.

Eastman Research Laboratory,
Rochester, N.Y., October 25.

THE KEEPING PROPERTIES OF AN M-Q DEVELOPER.

To the Editors.

Gentlemen,—In June, 1914, I made up an M-Q developer for lantern plates to the formula of Messrs. Wratten & Wainwright, namely, metol 10 gms., hydroquinone 5 gms., sodium sulphite (cryst.) 100 gms., sodium carbonate (cryst.) 100 gms., water to 2,000 c.c.s. A portion of it was bottled in one-ounce stoppered bottles with perfectly-fitting glass stoppers and kept unopened until to-day.

Upon comparison with a freshly-compounded developer of the same ingredients it was found to have suffered slight discolouration, amounting, however, to a mere pale brownish tinge.

A lantern plate (Paget "slow") was exposed behind a step plate of known densities, the steps being in the form of bars completely across the narrow diameter of a quarter-plate. The lantern plate so exposed was cut longitudinally into two halves. It was assumed that each half had received an identical series of exposures transmitted by the steps of the step plate.

The following data were obtained after development at a temperature of 65 deg. F., kept constant in a thermostat throughout development:—

Densities of the step plate.	1914 M-Q. Densities (diffuse).	1922 M-Q. Densities (diffuse).
Fog strip ...	0.00 ...	0.00
2.150 ...	0.050 ...	0.050
1.675 ...	0.175 ...	0.175
1.125 ...	0.600 ...	0.625
0.700 ...	1.025 ...	1.050
Time of first appearance of the image ...	4½ secs. ...	6½ secs.
Total time of development ...	50 secs. ...	70 secs.
Watkins' factor ...	11 ...	11
Approximate Gamma (contrast) ...	1.0 ...	1.0

In both cases the developer was diluted with three times its bulk of water in order that the time of first appearance of the image could be determined more readily, and development was arrested by plunging the plates, without washing, into cold acid "hypo." I am at a loss to explain why the older solution should possess the greater activity, unless it be that the ingredients in 1914 differed somewhat markedly from those used in 1922. In 1914 the metol and

hydroquinone were of German manufacture, and the sulphite of soda and carbonate of soda were both of the crystalline variety and of unknown purity. In 1922 I used Elon and hydroquinone (Kodak) and an anhydrous carbonate of soda (monohydrate) with an equivalent weight of 124 compared with 286 for the crystalline salt. Titrated with acid the alkalinity of the 1914 solution was the same as that of the 1922 solution.

It would, at any rate, appear that an M-Q developer properly compounded and kept in an air-tight full bottle retains its developing properties to a remarkable degree. And it is interesting to note that the time of first appearance of the image, an event the importance of which but few photographers recognise, was an accurate guide to the speed of development. With this developer a Watkins factor of 11 will reproduce the contrast of the original.

Yours faithfully,

Sunnymere, Birkenhead Road, Meols. B. T. J. GLOVER.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

S. W. N.—The celluloid buttons are a specialty of Messrs. Dorrett & Martin, 16, Belle Vue Road, Upper Tooting, London, S.W.17.

S. G. H.—We do not know what has become of him. For some years past he has not replied to our annual circular sent out for the compilation of the directory of the photographic trade in the "Almanac."

V. M.—We have not reprinted in book form any of the articles on docketing systems for the studio. The most detailed description of such a system was that recently given by a contributor, "Pelham Swinton," in the "B.J." of May 19 and May 26 last. These copies can be supplied by our publishers, price 9d. each, post free.

A. A.—We have seen the displays in the showrooms of the General Electric Company of the daylight half-watt lamps, but we have not had any of the lamps sent to us by the company. Inasmuch as the principle of the lamp seems to be a screening of the light of the ordinary Osram filament, we cannot imagine that the lamps can possibly reduce exposures in comparison with ordinary half-watts of the same wattage.

H. S.—We are quite sure that to make a good job of the book plates there is no better process than carbon. When you have your design you could send it to the Autotype Company, 74, New Oxford Street, London, W.C.1, who could make a negative of it and print in any colour of carbon tissue. They have some 30 or 40 different colours, among them a number of grades of blue.

A. H.—(1 and 2) The type of softness obtained direct in the camera by the use of a soft-focus lens takes a form which has a distinctive effect of roundness, while that obtained in enlarging a sharp negative with a soft-focus lens is merely the softening of lines. (3) Most of the well-known lens makers supply soft-focus lenses, and you should write to them for their booklets, which describe and illustrate the work of such lenses. (4) The Kodak diffusion disc may suit your requirements. Particulars of this attachment may be obtained from Messrs. Kodak, Ltd., Kingsway, London, W.C.2.

S. B.—It is just possible that contamination of the sulphide bath with traces of alum may have some effect in favouring the staining of the cards, but we would not describe its influence in stronger terms than those we have just used. We think it is more likely that the stain arises from insufficient fixation of the cards. If we were you, we should revise your procedure to the extent of passing all cards through two fixing baths in succession, leaving them in each for at least ten minutes. As soon as bath No. 2 has been in use for any considerable number of prints it should be made bath No. 1, and fresh full-strength fixer brought into use as No. 2. We are inclined to think that if you devote this special attention to full fixation you will not experience the staining of the highlights.

A. V.—So far as concerns the photographs of the buildings, we imagine that the copyright in them was the property of the previous photographer. You have certainly not acquired the copyright in them, and both in copyright law and common law the previous photographer, we think, can restrain you from showing the prints on your premises when, presumably, they would be represented as your own work. We dare say he could also restrain you from selling them. As regards the portraits, the circumstances are more complicated. We must assume that the portraits were taken in the ordinary way of business, and that, therefore, the copyrights belong to the respective sitters. These latter, if they are so inclined, may object to the exhibition of the prints and have the right to restrain you from exhibiting them. We should think the simplest thing would be to write and ask their permission.

S. S. C.—The copyright in the photograph of the church has certainly been infringed, and the church authorities, who ordered the production of the handbook by the printer, are equally liable with the printer in respect to the infringement, so also are any traders who sell the handbook. We should think your best course would be to write to the secretary of the bazaar, pointing out the infringement and his liability in the matter. The Act authorises you, by taking action, to obtain delivery to you of all the infringing copies of the publication. In these circumstances no doubt the secretary will be only too anxious to rectify what may have been an oversight. You should ask him what he proposes to do about the matter. Do not ask for any particular fee. As a rule, photographers whose work is infringed in this way are ready to accept in satisfaction twice the fee which they would have charged had they been approached in the first instance.

S. B.—(a) Apart from the illustrated daily and weekly Press dealing with news events, it is customary to send direct. And it is better to do so, since the agents have their rounds, which very often do not include the more specialised journals. As regards illustration of poems, you might send a dozen or so prints of a kind which could be used for this purpose, and at the same time intimate that you are ready to take photographs for illustration of a particular poem or story. A book which would be of great use to you is "The Writers' and Artists' Year-Book," published by Messrs. A. & C. Black, Ltd., 4-6, Soho Square, London, W.1, price 3s. 6d.; also Willing's Press Guide, published by Messrs. James Willing, Ltd., King Street, Covent Garden, London, W.C.2, price 2s. (b) As regards photographs for advertisements, almost all these are prepared by a firm's advertising agent. You can only discover which agents deal with a firm's regular advertisements by studying the advertising Press, such as "Advertiser's Weekly," 66-67, Shoe Lane, London, E.C.4; "Advertising World," Sardinia House, Kingsway, London, W.C.2; and "Sales Management," 34, Bedford Street, London, W.C.2.

Contents.

SUMMARY

In a contributed article Mr. A. E. Bawtree describes some methods which, while saving time, do so without sacrifice of accuracy. They relate to printing of margins, making of solutions, cutting plates to size, etc. (P. 691.)

In a recent lecture before the Master Printers' Association, Mr. W. Gamble gave an excellent account of the advances which are being made towards the substitution of photographing machines for those now employed in type-composing for letterpress printing. He described what has actually been accomplished in this direction, and showed its relation particularly to offset and intaglio methods of printing. (P. 692.)

At the Royal Photographic Society, on Tuesday evening last, Mr. K. C. D. Hickman described a method of sulphide toning with gaseous reagents, namely, bromine or chlorine, and hydrogen sulphide. The process was put forward as adapted for the continuous toning of photographic images by mechanical means. (P. 701.)

In an article by J. De Witt Kreps, contributed to "American Photography," the author gives many useful hints by way of introduction to the practice of the ordinary retouching of negatives with a pencil. (P. 698.)

In the use of half-watt lamps care should be given that the bulb is in the position intended by the makers, that is to say, with the socket immediately over the filament. (P. 689.)

We refer to a remarkable example of the trade done in connection with the development and printing of amateur film, namely, the making of nearly 30,000 enlargements within a period of eight months in a single business. (P. 689.)

A camera for the making of portraits to be delivered immediately to the customer is the subject of a recent patent specification. (P. 699.)

In a leading article we refer to some of the appropriate ways in which the photographer's showcase or window may be dressed with specimens appropriate to the season, and thus more effective in attracting business. (P. 690.)

Lenses may readily be fitted for temporary use on a camera by one or other of the devices described on page 690.

Practical details of the method to be followed in eliminating the dot effect when copying an impression from a half-tone block are given in a paragraph on page 690.

Full exposure and development, followed by the use of the iodine-cyanide reducer, is probably the best way of dealing with stale bromide paper—better than the use of a restoring solution. (P. 690.)

EX CATHEDRA.

The Position of Glow Lamps. The daily increasing use of incandescent electric lamps for portrait work and enlarging renders it necessary to point out to those who are fitting their own half-watt installations that the life of the lamp depends greatly upon the position in which it is fixed. It is, of course, supposed by the manufacturers that the lamps will be fixed in a pendant position, the socket being immediately above the lamp. The interior of the bulb is so arranged that the filament is most effectively supported in that position. Moreover, the higher powered lamps generally used for studio work have an arrangement by which any volatilised matter from the filament is condensed in the neck of the bulb if the latter is kept in its normal position, thus deferring to an appreciable extent the blackening of the bulb in the neighbourhood of the filament. Fortunately it is usually easy to fix the lamps normally for portrait work. In the case of enlarging lanterns, a mirror fixed at an angle of 45 deg. below the lamp will allow the circle of light to be directed to the condenser. Surely it is time the manufacturers gave us some small half-watt focus lamps for fairly high voltages.

* * *

Enlargements and D. & P. While it is generally recognised that the business of developing and printing the film spools of amateur photographers runs into large figures, and during the last year or two has proved one of the most profitable branches of the photographic trade, we imagine that many people still fail to appreciate the magnitude of the business which passes along these channels. A vivid side-light on the business is shown by an article in the current issue of the "Kodak Trade Circular," in which is an illustrated interview with Miss Elsie Graham, an employee of Mr. A. E. Marriott, of Hastings, who is responsible for the production of the enlargements which are supplied by Mr. Marriott, largely, we believe, in connection with the latter's business of developing and printing film spools. Within a period of eight months Miss Graham has made enlargements to the number of 29,524. The total is in itself a testimony to the capacity for output of the Eastman projection printer, with which the work has been done, but we should like to underline its significance in relation to the great volume of business which follows in the train of the use of daylight film cameras. After all, the making of enlargements is only a branch of the D. & P. trade, and probably there are not many people in the country who have developed it to the proportions which Mr. Marriott's output represents. The enlargement side of the business is, however, one which is capable of very great expansion, as, indeed, we discussed in an article a few weeks ago, written before the present record, as we imagine it to be, had come under our notice. In the early days, professional photographers held aloof from

this business, but many of them are now realising their mistake, and are seeking to get their share of it. Fortunately, owing to the modern developments of appliances for the business, it can now be taken up under immensely better conditions even than was possible five years ago.

* * *

Copying Half-tone Originals. There are different ways of obtaining a negative from a half-tone reproduction so as to get rid of the dot effect; all the methods, however, have a tendency to soften the reproduction and reduce the contrast. One of the best methods is to take a piece of acid-etched ground glass and smear the matt side with vaseline and polish off until all smears and greasiness have disappeared. The ground glass thus prepared is laid on the copy, matt side outwards, and then slightly drawn away until the dot effect disappears. The distance which is required depends upon the screen with which the original was made; it is usually about 1-16th to an 1-8th of an inch. The distance is retained by inserting a thin piece of card of the required thickness between the original and the ground glass. A fine "Metzograph" screen will give the same result with greater sharpness than is given with the ground glass. The dot effect can also be eliminated by putting the copy slightly out of focus, or by tapping the camera during exposure. Soft-focus effects can be obtained from hard outlined originals by the first method, but the negative should be fully exposed and well developed.

* * *

Temporary Lens Fitting. It is often necessary for the technical photographer to extemporise some form of holder for a borrowed lens or for one which time does not allow to be properly adapted. The iris grip holder which, we believe, is now again to be obtained in the ordinary way, is a very efficient solution of the problem, but it is unfortunately rather clumsy and therefore not adaptable to light cameras. In such cases it is necessary to fall back upon the old device of a rather thin but hard cardboard front cut out so as to fit closely up to the shoulder of the body ring thread and, after placing it in position, to clamp it by screwing the flange on the other side of the card. The card may be cut to fit into the camera front or may be fixed with drawing-pins upon a wooden panel. If the flange be not available, a stouter piece of card may be used and the lens screwed into the hole, which should be a tight fit. With heavy lenses such as large anastigmats and portrait lenses, a thin wooden front with an opening just large enough to take the screw thread should be made and the lens secured in its place with three or four small wooden buttons which will grip the rim in front of the body screw. A lens of 4½ inches diameter may be usefully held in this way without a flange.

* * *

Utilising Stale Bromide Paper. Although when properly stored, bromide paper will remain in good condition for a considerable period, it sometimes occurs that some long-kept stock is found incapable of giving a clean print. A muddy grey fog pervades all the high-lights, and in addition there is often a somewhat metallic stain round the edges. The best way of dealing with such paper is to give a full exposure and development and, after the usual fixing and washing, to clean up the surface with a very weak iodine and cyanide reducer. This is best applied by means of a fairly large pad of cotton-wool instead of immersing the print in a dish, since not only is less solution required, but it can be applied locally to any obstinate stain without endangering the rest of the subject. If the image is fairly strong, there is little risk of destroying any of the delicate half-tones before the fog is removed. Only a few minutes' washing is necessary after the clearing. It is rather important that a fairly pure sample of cyanide be used, since some of the common qualities as sold for non-photographic purposes are of themselves liable to cause a yellow stain. No doubt bromide paper can be improved for printing, though at the expense of its speed and gradation, by treating it with one or other of the restoring solutions which have been recommended, such as those containing permanganate. But for anybody whose time is of any value the game is scarcely worth the candle. After all has been said and done, the preventive of staleness is in the photographer's own hands. If the conditions of storage are unduly severe through damp or heat, a good-sized tin trunk may be set apart for containing the stock of bromide paper in a cool place, and the internal atmosphere of the box kept dry by putting a few pounds of calcium chloride inside.

SEASONABLE SPECIMENS.

Most photographers are alive to the necessity of making a special display as Christmas approaches, and some even rise to the occasion to the extent of adding to the attractiveness of such a show artificial holly and genuine cotton wool. The more discerning, however, realise that after all it is the pictures that matter, and that a descent to the level of the toyshop is neither dignified nor profitable. Moreover, the Christmas decorations cannot be put out sooner than the beginning of December, which is rather too late to start the Christmas trade. A better plan is to arrange, week by week, a special show of some subject appropriate to the season. Let it be fancy-dress portraits and groups one week; ladies in furs the next, and home flashlight groups for a third. In addition, local celebrities and happenings may be pressed into the service, the one object being to make the window attractive.

Such displays need not necessitate a great amount of work, since half a dozen subjects in a fairly large size should be enough for each. Again, it may be pleaded that suitable negatives are not on hand. In such case, the obvious remedy is to make them. It should not be a difficult matter to enlist the sympathies of the local draper or furrier by pointing out that a display of photographs of fur-clad ladies is likely to stimulate the demand for his goods, while he could possibly help still further by providing young lady models, who would feel amply recompensed by a few prints. Child pictures are always a certain draw, but these should be kept separate from grown-ups, or they lose their appeal.

So far, there is nothing very Christmassy in the idea, but once interest in the studio is excited the suitability of photographs as gifts is easily demonstrated. One difficulty which arises is that many people feel that a photograph is rather a mean gift to offer, but this may be overcome by adding to it an appropriate frame, case or wallet. The narrow mouldings now in vogue make extremely tasteful yet inexpensive frames, and there is no reason why, by adding a seven-and-sixpenny frame to a cabinet, it should not be regarded as a worthy present. For some unknown reason many photographers entirely ignore the possibility of selling frames, while others make a satisfactory addition to their turnover by pushing them. It is the same with pocket cases and wallets. Why should customers have to go to a stationer's to get these, often in unsuitable styles and colours, when the photographer could supply just the right thing?

It is difficult to lay too much emphasis upon the importance of exhibiting specimens or samples of the highest possible quality. In ordinary commerce, where goods are sold from samples, there is a warranty, written or implied, that the bulk is equal to the sample. It is only the photographer who is sometimes foolish enough to use rejected proofs and faulty prints to show the quality of his work. Far better is it to make an extra print on each order from such negatives as may appear to be suitable, and to choose the best and not the worst of the dozen as a specimen.

Suggestions as to window dressing have already been given at sufficient length by many writers, but it may not be out of place to say here that the worst of all faults is overcrowding. When a window is crowded with portraits it is difficult to see the good points in any one of them. One is simply conscious that it is a photographer's, and if there is any pressing need for a portrait, one enters, that is, if not too critical.

As in all other businesses, it is a paying proposition to show from time to time some special line, and to suggest that quite the same thing cannot be obtained elsewhere. Such things as inexpensive miniatures on real ivory, ceramic enamels, special styles in framed enlargements, are all suitable for presents, and the busy photographer need only take the negative and leave the rest to a good trade house.

It is, perhaps, hardly necessary to point out the advisability of keeping the window display uncovered and lighted up as long as there are any possible customers about. Young couples are good friends to the photographer, and it is well to give them a chance of seeing what can be done in the way of photography after their own business hours are ended.

While it is not always desirable to undertake what is now called "amateur finishing," some photographers have found it worth while making carefully-finished monochrome or coloured enlargements from amateur negatives. It has happened more than once that a snap of a favourite dog or horse has resulted in an order for an oil painting as a birthday or Christmas present to the owner of the animal.

TOUCH *v.* SIGHT IN PHOTOGRAPHIC MANIPULATION.

At first sight it would scarcely seem possible to suggest a greater contradiction than that operations in the one process dependent upon light could be better performed by touch than by sight. Yet this is true in certain fields. Obviously one cannot judge the colour of toning or the extent of development by means of the fingertips, but whenever repetition work has to be done, and in many cases in which speed of operation is concerned, the hands are the best guides.

This principle is very widespread in factory work. In all metal stamping machines the sheet is placed in position against stops by touch. For filling bottles with patent medicines, hat polishes and so forth, each bottle is placed in turn in the angle of a right-angled guide to ensure that the small mouth shall come exactly under the delivery spout of the filling machine. Even more closely associated with the photographic industry is the matter of commercial colour printing. Here each working is made to register with the last, not by placing the sheet with a mark opposite one on the board of the machine, as is often done in multiple carbon printing, but by pressing each sheet home against a rule along one edge and a stop which touches a second edge of the sheet. Having once set the stops, far superior register is obtained than could possibly be secured by eye, and every sheet is positioned just as quickly as the operator can handle it.

The first application of the method of touch is similar to that just described for colour printing. It has reference to the narrow white margin which serves in lieu of mounting in the case of the thousands of prints turned out by those firms who "develop your films and let you have prints in 24 hours." Masks are cut in sheet zinc, as thin as possible, say of No. 6 zinc gauge, having openings a little smaller than the exposed portion of the various sizes of negatives to be handled. These openings should be about a quarter of an inch smaller each way than the sensitive paper, which is obtained cut to size in gross boxes. About one-eighth of an inch from the opening strips of thin card are glued to the zinc on all four sides, extending to within a quarter of an inch of each corner; this card thus forms a shallow trap, which will just hold the cut sensitive paper and at the same time permit it to be lifted out by a finger-nail under a corner. The print is thus automatically masked with a margin of uniform width of an eighth of an inch. The edges of the paper become slightly frayed in manipulation, and the final trimming is done on a well-known type of trimmer, designed for post cards, which automatically takes off a sixteenth of an inch from the sheet, just as quickly as the hands can move, and without any adjustment by eye at all. The saving of time by this method is considerable, amounting to about fifteen seconds per print, or an hour for every twenty dozen. At the same time the consumption of sensitive paper is reduced to the absolute minimum.

When black margins are required, a course adopted by the more artistic "D. and P." concerns for prints from the many flat, over-exposed negatives with which they often have to deal, the print is first made from the negative without any mask at all. Upon a piece of glass of, say, half-plate size, two strips of thin card are pasted near two adjacent sides and truly at right angles to one another. A piece of carefully trimmed black paper is affixed also to the glass, leaving a space of one-eighth of an inch between it and the two pieces of card. Thus the only uncovered portion of the glass is an L-shaped line an eighth of an inch wide. The printed paper is placed against the card strips, and a short exposure given. It is then turned so as to bring the other two sides against the strips, and a second exposure made. When developed and dried any roughness of edge is trimmed off with the automatic trimmer above referred to.

The making up of photographic solutions by touch saves a lot of time. Tin canisters, thimbles, potted meat pots and other small receptacles can be adjusted to hold the required weight when filled level with the top, labelled with the weight and nature of material and all weighing of chemicals for regularly used recipes thereafter saved. For example, a canister 3½ in. high by 2½ in. in diameter, filled with hypo crystals and tipped into a one-quart bottle, which is filled up with water, makes a 25 per cent. hypo solution. Tin or cardboard vessels can be cut down to the sizes required, while pots or thimbles can be partially filled with wax in order to obtain adjustment. A mixture of beeswax, 3 parts; rosin, 1 part; and brick-dust, 1 part, is ideal for the purpose.

Compounding developers, toning baths and similar mixtures from stock solutions can be similarly expedited. In place of carefully filling a measure up to the line with each component in turn, a far less costly tumbler or cup is used to hold the bulk, and small glass or china measures are used for the components, each of which has to be filled level with the top to

secure the proper amount. Egg cups, wine glasses, small fancy jugs and pots from the china shop and other odd vessels can readily be found to hold the correct amounts, and should be plainly marked in bold Brunswick black letters with their containing power when brim full. Not only is much time saved in daily work, but actually greater accuracy is secured, and therefore better uniformity of work, than when the ordinary graduated measure is employed.

The distinction of bottles by touch is preferable to the best labelling, though, of course, the bottles should be labelled in addition. What photographer is there who has not many a time taken up the wrong bottle because it was of the same size and shape as the one required? A row of uniform Winchesters and similarly sized and shaped reagent bottles may look very nice, but a miscellaneous assortment of glassware from grocer and oil shop will conduce to better and more certain work.

In multiple-gum or any other type of printing in which successive impressions are put upon the same print, adjustment by touch gives more exact results. If a picture is being copied fine lines should be marked near two edges, while where this is not possible, as with landscapes, lines should be drawn upon each negative between definite points on two adjacent edges of the negatives. Strips of thin card can then be pasted up to these lines, and will give perfect register stops for all printings.

For studio work and experimental photography very much expense can be saved by making all trial exposures on half quarter-plates. The writer has cut thousands, possibly tens of thousands, of plates up into various sizes both for the above purpose and for other cases of plate economy. When, for example, a number of narrow negatives have to be made, it is well worth while cutting plates especially for the purpose. In his recent exhibit at the R.P.S. 24 negatives were required of a length of 8 in., but only containing an image an inch wide. Whereas the general plan would have been to use whole plates for these, plates were employed only one-third of a whole plate in width for these results. Thus only eight were required, and sixteen saved. With plates at their present price this economy is very marked. The little appliance for cutting by touch is easily made as follows:—From a local printer obtain a few feet of "pica wood furniture." Also obtain a small drawing-board, say a foot square. Along two opposite edges of the face of the board glue strips of the furniture. Cut a third strip long enough to reach right across the board to the outer edges of these two strips. Secure the strip at one end on the top of one of the fixed strips, so that its outer edge comes to within a quarter of an inch of the edge of the board. Swing the strip by the other end till it is exactly at right angles to the strip, to which one end is screwed, and then secure the other end to the face of the other strip. This third strip will now form a bridge the whole length of the board, under which glass plates can be slipped. If the plate is pressed against the nearer edge to the operator (to which the strip should be strictly at right angles) a cut with a diamond guided by the bridge will cut the plate square across. Draw the cutting diamond alongside the bridge, making a mark on the quarter-inch wide margin of the board which projects beyond this edge. Now mark the board every quarter of an inch from this mark, and impress these marks deeply into the wood with a screw-driver or blunt chisel. Make each inch mark twice as long, and plainly mark the inches. Eighths and sixteenths can easily be judged between these marks. As an example of the use of the board; suppose it is required to cut whole plates up into three approximately equal strips, stick an ordinary pin firmly into the wood at the distance $2\frac{1}{8}$ in, full. Take two plates face to face, place them with one of the $6\frac{1}{2}$-in. sides against the near strip of wood, and one $8\frac{1}{2}$-in. edge touching the pin, and make a cut with the diamond. Turn the two plates through half a revolution and make a second cut. Turn the two plates over and repeat the two cuts, when the plates can be broken into six strips of the widths desired. The writer always uses this device for plate-cutting in total darkness, only using light for setting the positions of the guide pins.

When prints or sensitive paper have to be cut to uniform size, adjustment on the trimmer by touch is quicker and more accurate. Strips of thin card should be pasted down on the board of the trimmer parallel to the knife and at the desired distance from it. A number of charts have been prepared, each containing nine rows of twelve separate pieces of coloured paper, two of which charts appeared in the writer's exhibit at the R.P.S. last year. These little 1-in. squares fitted with beautiful accuracy, and were all cut by touch in the manner above indicated.

Other examples of the idea might be given, but enough has been said to indicate the possibilities of work by touch rather than by eye. It can be laid down as a general rule that whenever touch can be substituted for sight there will be substantial gains both in speed and in uniformity of results.

A. E. Bawtree, F.R.P.S.

THE INFLUENCE OF PHOTO-OFFSET AND ROTARY PHOTOGRAVURE ON THE FUTURE OF LETTERPRESS PRINTING.

[At a recent meeting of the Master Printers' Association Mr. W. Gamble read a paper in which he gave a very interesting description of the progress which is being made in the application of photographic methods to the production of letterpress. For some years past several inventors have been busy in the design of machines akin to those now employed in typographic work, but designed to produce photographic negatives instead of the matrices from which type is cast by such machines. The inventions open up revolutionary methods in the production of letterpress, particularly in relation to printing by offset and photogravure methods. The lecture, the chief part of which, by courtesy of Mr. Gamble, we are able to print, shows the various ways in which progress is being made, and foreshadows the changes which may come about in the printing industry as the outcome of the substitution of photographic for mechanical methods.]

The increasing use of photo-processes for various kinds of printing and the great improvement which is being continuously shown in the results of these methods, especially in connection with offset printing, are leading letterpress printers seriously to ask the question how these developments are going to affect their branch of the printing industry. I propose to address myself to answering that question so far as it is possible to do so in the light of present knowledge. To answer it completely would require the prescience of a prophet, for no one can exactly foresee how these new processes will eventually develop. One can only indicate by deduction and inference the direction in which they may tend.

So long as these photo-processes were confined to the production of illustrative matter, whether by blocks or by lithography or by photogravure, letterpress printers did not view them with any alarm, but rather looked on them either as a valuable auxiliary to their business or as useful for special purposes outside

the province of typographic printing. But when it is seen that an increasing amount of text matter is being printed by offset and rotary photogravure, and that the results are very good, even being preferred by some customers, letterpress printers naturally begin to ask where they stand, and what is the future going to bring forth.

At first they consoled themselves by the reflection that so long as the type had to be set before it could be used for either offset or rotary photogravure there was not much to fear, as there could hardly be a great difference in cost. When, however, there were rumours that before long it would be possible to compose text-matter without setting type the trade began to "get the wind up," as the saying goes.

In the last two or three volumes of "Penrose's Annual" I have given evidence that inventors are at work on such methods, and that some of them have actually achieved pretty good results. I also warned the trade what was coming in my address to the World's Printing Trades Congress held at the last Printing Exhibition, but my remarks were viewed with scepticism. I am able to show you some proofs of the work of Mr. Arthur Dutton, of Liverpool, which I think you will agree are very good evidence that progress is being made towards the realisation of this idea of composing without type. You will see that he is able to compose either display or solid matter and ornamental borders, that he can justify his lines, and that from one set of master letters equivalent to a face of type he can get any size in the point scale. You will also see that the alignment is good, and that the lettering is clear and sharp. I am not permitted to tell you how it is done, but I have seen the apparatus at work, only a rough model, yet sufficient to produce the remarkable work I am showing. It only needs the construction of an apparatus hardly more complicated than a typewriter, and certainly far more simple than a linotype or monotype.

There is also on the market already in New York an apparatus called the "Deastype," which produces very good display matter in the form of copy for the engraver or photo-lithographer, but it does not seem adaptable for solid text.

You have all no doubt heard of or read about the patent of Messrs. Robertson, Brown & Orrell, which emanates from the house of Robertson of St. Annes, the firm who have made themselves famous for the production of the "Blackpool Times" and the "Sunday Express Supplement" by offset printing. Their apparatus is to be something like a linotype machine in appearance, only instead of matrices there are little frames of metal containing glass negatives or positives of the letters of the alphabet. When a key is touched a letter comes down, and thus a line of letters is built up. Then the camera comes into operation, a beam of light is directed through the glass letters, and an exposure made. The camera makes a step, and the next line is set up and similarly photographed. So the operations go on until a column or a page is composed. The photographic images are reviewed on a celluloid film in negative form, so that as soon as the film is developed it is ready for printing down on zinc.

I know the question will be asked, "What about corrections?" Well, that can be done by cutting out a piece of the film, just as the cinema man cuts out portions he does not want and joins up again. There is no difficulty about that. I can see some other difficulties which all inventors in this field will meet with, but I do not think they are insurmountable. When you think of the marvellous results which have been achieved by the cinematograph, and the perfection of mechanism attained, I do not think we can look upon photo-composing as a more difficult problem. Or, again, it is not one-quarter, perhaps not one-tenth, as difficult as the work which has had to be done in perfecting the linotype, the monotype, and other type-composing machines.

Do we realise what the change portends? If there is no type to be set a whole lot of things go overboard with it. There will be no type casting, no stereotyping, no electrotyping, no block-making wanted, and if these things go so also goes the greater part of letterpress printing machinery. What a colossal change it will be!

I am told that in a certain printing works employing some 50 to 60 compositors and monotype operators, the capital outlay involved in type and metal amounts to between £8,000 and £10,000. There is also an equipment of three monotype keyboards and casters which, with the stock of matrices, have cost £4,000 to £5,000. Say in round figures, there is a capital outlay due to type setting of £15,000. Suppose this was replaced by photo-composing machines. I reckon that such apparatus could be sold for about £250 to £300 per unit, but, of course, there would be some additional outlay for the master alphabets for the photo-composing apparatus, but it will be nothing like that for matrices, because one alphabet for each face will yield any point size by reduction of the image with the camera. If we put the cost of the alphabets at £50 more, we have a cost per unit of £300 to £350. Now it is difficult to say how many units would be required to replace the work of 50 or 60 men doing monotype and hand setting, but suppose 10 unit machines would do that, then you would get for £3,500 an equipment equivalent to that which has cost £15,000 under the old system. There is, therefore, a good margin for adding more machines, or in case the machines should come more expensive. They will occupy little floor space and require no power. Some electric light will be wanted, but this will not be a serious item. There will be the expense of photographic plates or films and chemicals, but it will be nothing like so much as for type metal.

As to the labour cost, there may not be much difference against operating a monotype or linotype, as a skilled operator will be needed, but the work will probably be done more quickly; in fact, as quickly as on the typewriting machine. A man will be wanted to develop the films, but he will be able to keep pace with several keyboard operators. Another man will be wanted for laying down the films according to the imposition required, and in a large shop a man for printing down on the metal and preparing the plate ready for the machine. In small shops one man could probably carry through all the operations, but in large newspapers and book offices the operations would naturally be subdivided. In any case the work would go much more quickly than type setting, and of course stereotyping would be saved on large editions.

So far I have assumed that offset plates would be prepared, but machine builders have yet to prove that they can get a speed equal to the stereo rotary. The films prepared by the photo-composing machine could, however, be used equally as well for making photogravure cylinders, and we know that with rotary gravure printing an equivalent speed to the stereo rotary can be got. It may even be more convenient for a time to use the film negatives for making etched plates or blocks, sterotyping them for the news rotary, as was done with typescript by several provincial newspapers during the recent strike. There will be no difficulty about doing that, and it would be a convenience, though not much gain. The fact that these photo-composing machines might be operated by women is not to be overlooked. The work would be no more difficult than typewriting.

Probably photo-composing is likely to be more useful for newspaper and periodical work than for job printing. Think what it would mean for a newspaper having from 40 to 50 linotype machines with all their attendant equipment, to say nothing of the stereo plant, and the costly and elaborate printing machines necessitated by the system employed. If the type-setting and stereotyping can be dispensed with, the whole mechanical system for turning out a newspaper becomes vastly simplified and cheapened.

Of course, where illustrations are required there will be additional photo-process plant, but it will not cost so much as the equipment for block-making, because the equipment for routing, bevelling, sawing and planing the blocks will not be wanted.

As regards cost of printing machinery, there may not be very much difference between machines of equivalent size, whether for letterpress, offset or photogravure so long as sheet-fed machines are used, but for an all-rotary perfecting machine for newspaper work the photogravure machine will cost much less than the stereo rotary.

Whichever way we look at it, I feel sure the change from typographic to photo-process methods will mean cheaper plant, cheaper production, less labour cost, and reduced overhead charges.

You may ask why it would not be possible to utilise the photographic negative for making blocks instead of printing plates for offset or cylinders for rotary gravure? The answer is that though this course is quite possible, it is not economical. When negatives are printed direct on to zinc offset plates the process work is ended, and the plate is ready for the printer, and in the same way when work is put on the copper cylinder for gravure there is much less for the process man to do than in making blocks. When blocks are to be made, the image put down on the metal plate has to be etched, fine etched, routed, bevelled, proofed and mounted. When the printer gets the blocks he has to fit them into the formes, possibly has to underlay them, and certainly has to spend a good deal of time making ready. There is no make-ready in either offset or gravure printing. Half an hour, or an hour at most, may be spent

perhaps in getting things in working order for the run, adjusting impression, flow of ink, and damping mechanism in case of an offset machine, and in the case of gravure there is a similar tuning up to be done, but it is a small matter compared with the time spent in making ready a forme, especially a large forme of blocks.

The printer with a purely letterpress plant may say that the advantage gained is not sufficient to justify him in going in for offset or rotary gravure. It would mean installing a new plant and a new department of the business. But the economy does not end there. It is to be found also in the ease with which large sheets with a number of repeats can be laid down very cheaply, whereas to do the same thing by letterpress would mean having stereos or electros, which would be much more costly. This expense would be greatly increased if a colour job has to be worked. In the case of a small label, in two, three or more colours, letterpress would be quite out of it in price, for it could be put down on the plate by the step and repeat process at far less cost than by using blocks, and the number of repeats that could be printed on a sheet by offset would reduce the cost of machining enormously on a long run.

The lithographer may ask whether it would not be possible to achieve a similar result by transferring. He could not possibly do so against an efficient photo printing process. The mechanical devices which are now being so largely used in America for repeating subjects in the printing-down frame enable the work to be done very rapidly and correctly, especially for colour work. The second and subsequent colours can be laid down in absolute register with the first.

I am afraid there is some misconception as to the step and repeat method. It does not simply consist in making a stepped-up negative, as that is limited in size. There must be a further stepping in the printing-down frame to make up large plates, such as 30 x 40 ins., or 40 x 60 ins. The Americans seem to prefer to do all the stepping in the printing-down frame from one negative image, and I am inclined to think that is right. If it is desired to speed this up it is quite possible to make two or four exposures on one plate in the ordinary process camera, without resorting to an elaborate and costly apparatus. There are something like half-a-dozen devices being offered in America for stepping, whilst printing-down, and the latest known as the Bassist, is an extremely simple one, applied to what is practically an ordinary face-up printing frame. It is with such devices that the greatest development may be expected.

So far I have had in mind the preparation of plates bearing designs and illustrations from line or half-tone negatives. We have to consider also the printing-down of text matter. So long as type has to be set for it the procedure is usually that of pulling a good proof as copy for the process operator, who makes a line negative for printing-down. It is here where failure very often comes in. The letterpress printer does not seem to be able to pull a good proof unless he can make it ready on the platen press or cylinder machine. He has not achieved the skill of the photo-engraver's proofer, and too often he produces a proof which is squashed, the ink being spread and the impression too heavy. This is bad for the photographer. The lithographer is usually unable to pull a good letterpress proof, and thus the two branches of the printing craft do not help each other.

The Germans have got a process of printing the text matter on to a celluloid material, not the ordinary celluloid, but a special cellulose product which is very flat and flexible. A good sharp print is got on this and is dusted with bronze powder to make it more opaque. This celluloid print takes the place of the photographic negative for printing-down. Of course, it gives a white line print, but this is easily converted into a black line by a simple reversing process.

Photogravure workers adopt a similar plan by printing on translucent paper, and the Vandyck method used for the printing of maps and plans in the Government Offices is similar in principle to the method I have just described, the actual drawing being printed through instead of making a negative. Where work is already on stone or in type it is quite simple to take a transparent pull and use it instead of a negative, so long as the image is required same size.

A good deal of interest has been created by the Manul process. This is a method by which a negative can be produced from the pages of an ordinary bound book without using a camera and without damaging it in any way. The method consists in laying a specially sensitised plate on the page and allowing the electric light to shine on it. The rays go through the plate and are reflected back by the white paper, but not by the black ink. Thus the gelatine on the plate is hardened in the parts corresponding to the white paper whilst the rest corresponding to the print can be washed away. The film is afterwards dyed and stripped from the glass and a sheet of 64 pages can be easily printed from the films at one exposure. This is much cheaper than photography and requires less plant, but it is limited in its application to same size *fac-simile* work. A good deal of reprint book work is being done by this process.

Summarising the advantages of offset against letterpress, we may say :—

(1) That the cost of making the printing surface is cheaper than blocks and type formes.

(2) There is no make-ready.

(3) The printing speed is higher than on flat-bed letterpress machines.

(4) By using two-colour rotary offset presses either two colours can be printed at once or two sides of the sheet in one colour.

(5) It is unnecessary to use expensive coated paper.

(6) The consumption of ink is less.

(7) The power absorbed by a rotary machine is less than for a flat-bed letterpress machine.

(8) The capital tied up in keeping type formes standing is vastly greater than for keeping negatives and zinc plates. (A zinc plate for printing a 60 x 40 in. sheet costs from 20s. to 26s.)

(9) For colour work high lights can be printed without any grain or screen over the whites and with softly vignetted edges such as it is very difficult to get with block work, except by elaborate make-ready.

(10) Half-tones can now be printed on the offset press with quite pleasing results, and customers are preferring the soft effects to the hardness of half-tone block work on coated papers.

(11) The photo-process of the work is simpler and cheaper than making blocks.

It may be urged that for colour work there is no real substitute for fine etching, by which the most perfect results in block work are produced. This is being remedied by retouching on the negative and in developing the image on the plate. Processes are also being employed which claim to do without retouching, and very fine results are attained. Hitherto a good many of the failures of offset work have been due to the operators working half-tone and colour negatives in the same way as for blocks, whereas a quite different negative is required for photo-offset.

Grain-processes are now coming largely into vogue for photo-offset because such work can be rendered much better by it than by blocks.

Perhaps it may be urged that an offset plate would not wear through a long run so well as copper half-tone blocks. There is no very definite evidence on this point, but I may point out that it is easy to make a duplicate plate once you have the negatives.

So much for offset. Now let me refer to the bearing of rotary photogravure on the work of the letterpress printer.

As to the quality of the results of photogravure compared with either block work or offset, there can be no difference of opinion so far as single-colour work is concerned. Just consider the wonderful richness of the tones, the photographic fidelity of the result, and the absence of screen effects.

Undoubtedly the public like this kind of printing, and they buy freely the publications printed by its means. They recognise and appreciate this kind of printing as a relief and change from the monotony of half-tone.

As with offset, it is possible to print on almost any kind of paper. Even on the commonest newspaper the results are far away better than half-tone. But, of course, the more suitable the paper the better the result, and photogravure needs to be printed on good paper to show at its best.

The consumption of ink is very low—something like 1 to 1½ lbs. per 1,000 copies on a large news or periodical sheet.

The speed of printing is much greater than either offset or letterpress printing when rotary machines are used. For high-class work 4,000 to 5,000 perfected copies per hour are easily obtained, but for cheap newspaper work speeds of 24,000 to 32,000 copies per hour have been achieved in the *Cape Times* office.

There is no make-ready with rotary photogravure, and no special attention to secure uniformly good work throughout an edition is needed.

Thus the advantages are all in favour of photogravure for book, newspaper and periodical printing, but it does not compete with offset for commercial work, nor at present does it compete with either blocks or offset for colour printing. Its application to colour work is still in the experimental stage, but some very fine results have been obtained, and they give promise of greater achievements in the future.

One of the questions which arises in connection with gravure is the cost of cylinders compared with blocks or offset plates, though it is hardly a matter for comparison because the cylinders are used

with the special object of securing a certain result which cannot be obtained by either of the other processes.

Still, some comparison can be made without disadvantage to gravure. For plain, straightforward work, without elaborate lay-out and borders, the cost of a cylinder filled with pictures will be much less than the same area of blocks. It is not easy to figure the cost of gravure work on a square inch basis because the engraving and printing must be taken together.

I believe one house which works for the trade figures out the cost of engraving cylinders at 10d. per square inch of surface, but it can be done much cheaper by firms making their own cylinders. If there were 16 8 x 5 in. pages on the cylinder their cost would amount to £26 13s. First-class squared-up half-tones for the same size would come to £32 on the basic rate of 1s. per sq. inch. If, however, there were text and pictures to be reproduced the cost would be much more, as both line and half-tone blocks would have to be made and joined up.

Probably the cost of making an offset plate will be in every case less than making a cylinder, but no offset plate can ever produce the results of the best photogravure work. Soon, I think, it will be possible to print gravure from thin copper plates bent round a cylinder. Then, I think, gravure will compare very well with offset, and printers will be able to get these plates made outside as readily as they now get blocks or offset plates.

As to the possibilities of colour printing by the gravure method, progress is being made, and the results are most promising, but many difficulties have yet to be overcome. It is not possible to do anything on gravure cylinders equivalent to fine etching; therefore all the effects must be obtained in the negatives. This means a great deal of retouching unless some improved process of colour selection can be found.

Some very artistic results have been obtained in this country and in Germany and Holland on flat-bed machines and sheet-feed rotary machines. Colour work on all rotary gravure machines presents much more difficulty. Nevertheless, some excellent results have been got by a German house on a machine which prints all the colours simultaneously on a machine similar to that used for coloured wall-paper printing.

In America, the *Chicago Tribune* has for some months past been producing regularly a Sunday supplement in colours by gravure printing. I believe that the system employed is to produce first one cylinder as the key, and from this re-transfer to other cylinders, which are worked on by etchers accustomed to pricking out colours, who remove or add work as required. Each colour cylinder is put into a separate printing unit and the paper passes from one to the other. The Prismatone process which is being exploited in America is, I believe, a similar method for producing the colour cylinders.

The purely photographic method of colour separation presents difficulties for gravure, just as it does for offset, and much retouching must be done at present to get a passable result.

There remains much to be done to achieve prefect results in colour printing by gravure, but if it can be accomplished so as to make it a commercial process it will be a powerful competition to all other forms of printing.

W. Gamble.

THE MODERN CHEMISTRY OF GELATINE.

(In a recent communication from the Eastman Research Laboratory Dr. S. E. Sheppard reviews some of the most recent work which has been done in the complex problems which concern the part played by the gelatine in the making and use of gelatine dry-plate emulsions. These include the effect of imporities in the gelatine which reduce sensitiveness; viscosity and setting point of gelatine solutions; mechanical strength of jellies and their capacity for swelling; and the behaviour of gelatine in hardening fixing baths and on drying. The paper is being published in the United States in the "Journal of Industrial Engineering Chemistry.")

(*Continued from page 679.*)

Photographically, the viscosity of gelatine solutions and of silver halide emulsions is of great importance, since not only does it affect the formation of the emulsion, but also controls the operation of coating or spreading.

The average concentration of gelatine in emulsions is from 6 to 7 per cent., while the sequence of operations in emulsion making, particularly digestion in slightly acid solution at elevated temperatures may alter part of the gelatine; this is usually only a fraction of the total used. Hence, the viscosity of the given gelatine determines the viscosity of the emulsion, and thereby the coating speed. It is further interesting to note that the coating temperature is usually around 35 deg. to 40 deg. C.; that is, the region of the putative transition point.

(3) *Influence of Sensitiveness of Light.*

The early conception that the value of gelatine in photographic emulsions consisted in its functioning as a photo-chemical sensitiser, by absorption of halogen, has been largely abandoned. The most that can be definitely stated at present is that certain impurities must be reduced to a minimum.[11] In regard to the chemical analysis, we may note that the ash should not much exceed 1 per cent., that copper, lead and iron should be negligible, and chlorides low. On the organic side, organic sulphur, giving silver sulphide, should be absent, almost reducing substances (reducing ammoniacal silver nitrate in the dark within twelve hours) as well as greasy substances and mucins.[12]

Functions of Gelatine in Negative and Positive Making.

When we pass from the preparation and exposure to light of gelatino-silver halide emulsions to the operations leading to finished negatives and positives, it is the properties of the hydrogel which are of chief importance. First of these is the *jelly strength*, since, like the "wet strength" of paper, this determines the endurance in many stages of manipulation. Most tests for this, following the time honoured "finger test" for glues, have involved determination of the force required to press a plunger a definite depth into the jelly.[13] These methods are satisfactory for most industrial purposes. There is some possibility of error by "skin formation" at the surface, however, and no definite elastic constant is measured, since both compression and shear are effected in unknown proportions. For these reasons I have designed a torsion dynamometer exerting pure shearing stress on jelly cylinders. This instrument and its operation has already been fully described[14] so that it will suffice to state that "jelly strength" may be measured therewith, either by the *modulus* of *rigidity*,

$$N = \frac{\text{stress}}{\text{strain}}$$

or by the *torsional resilience* = ½ (stress x strain) at limit. Experiments with this have shown that gelatine jellies are rigid, and follow Hooke's law practically up to the breaking point. After moulding a jelly and keeping at 0 deg.—5 deg. C., the rigidity increases rapidly at first, and becomes constant in about ten to fifteen hours. Between 0 deg. and 10 deg. C., it does not vary much with temperature, but above 10 deg. rapidly falls, to become zero at the "melting point." The relation of the rigidity to concentration does not follow an identical curve with different commercial gelatines; but it is approximately represented by the equation

$$N = k\, c^n$$

where n approaches 2, but varies with different gelatines. On varying the hydrogen ion concentration of ash-free gelatine jellies I find for concentrations from 4 to 10 per cent. of ash-free gelatine a maximum rigidity (jelly strength) at about $p_H = 8$, above which the rigidity falls off rapidly. The decline from the maximum

toward lower p_H values is less steep, a flat portion or "shoulder" existing near the iso-electric point, but no maximum or minimum Below $p_H = 3$ there is again a rapid fall. Certain anomalies with commercial gelatine have been traced to the influence of inorganic ash constituents; thus aluminium, at .01 per cent. Al_2O_3 on dry gelatine greatly alters the curve, a secondary maximum being produced at $p_H=4$.

The Swelling of Gelatine and Photographic Operations.

In the operations of development, fixation, washing, after-operations, as reduction, etc., the most important property is the swelling of gelatine in water and aqueous solutions. It is this property

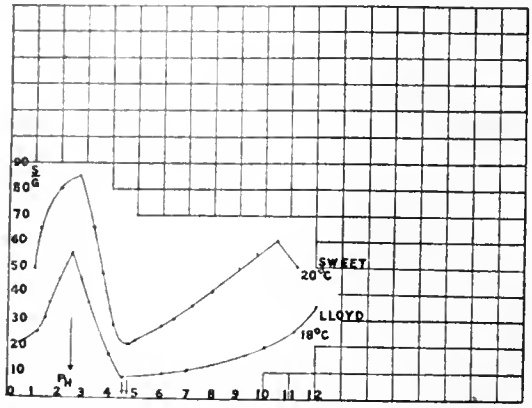

Fig. 4.—Swelling of gelatine in caustic soda and hydrochloric acid, S G=gms. water per 1 gm. gelatine.

which makes the gelatino-bromide, "dry" plate or film so amenable to the variety of operations used in photography.

Although much current theory is based on the idea that gelatine in swelling does so uniformly in all directions, this is not quite exact. In practice, previous conditions of drying largely determine the subsequent swelling. In the photographic emulsion the

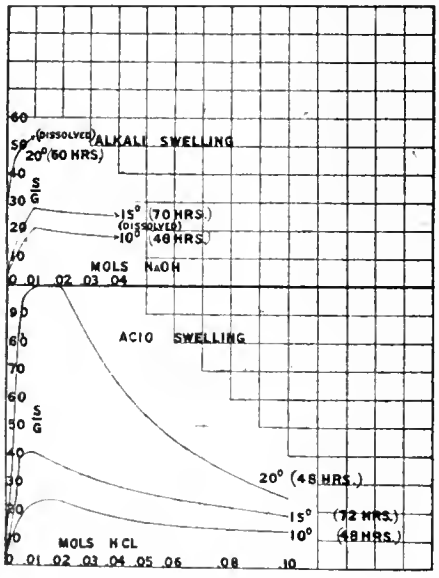

Fig. 5.—Influence of temperature on swelling limit.

adhesion to a rigid support (relatively) prevents swelling effectively taking place in any direction save that normal to the surface. Since swelling forces perpendicular thereto do exist, and come into play when the swelling is considerable, the support is substrated with hardened gelatine before being coated with emulsion. It has been known for some time that the swelling of gelatine depended decisively upon the acidity (or alkalinity) of the solution in contact. This has been developed by H. R. Procter, and Procter and J. A. Wilson, in terms of Donnans theory of membrane equilibrium, to explain the swelling quantitatively, at least on the acid side of the iso-electric point. This theory has been discussed very fully elsewhere[15], and it is not necessary to enter into details. Briefly, it is assumed that gelatine forms a readily ionizable salt with the acid; to secure membrane equilibrium the concentration of diffusible ions in the jelly phase is greater than that of the external solution. The tendency of the (diffusable) negative ions to diffuse outward is restrained by the cohesion

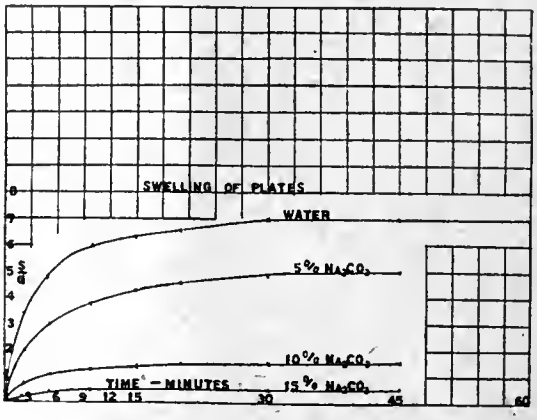

Fig. 6.—Rate of swelling of gelatino-silver-bromide emulsion in sodium carbonate solutions.

of the jelly, and the swelling (increase in volume) produced is proportional to the excess concentration of diffusible ion. The agreement of the calculated values with experimental ones is very satisfactory; J. Loeb has shown further that if swelling in acids of different concentrations is plotted against the p_H of the solu-

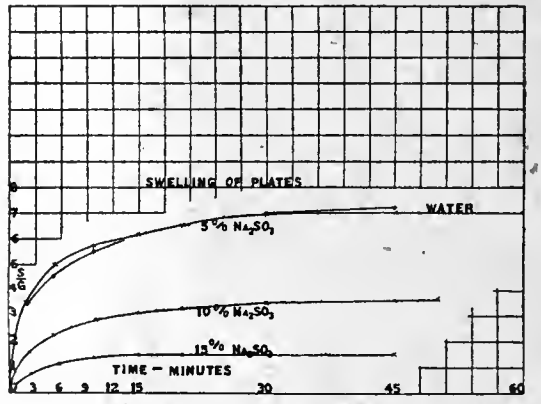

Fig. 7.—Rate of swelling of gelatino-silver-bromide emulsion in sodium sulphite solutions.

tion that all (effective) monobasic acids give nearly identical curves, sulphuric acid, as a dibasic acid giving somewhat lower values. Swelling on the alkaline side also passes through a maximum at a certain p_H. The general form of the swelling curve is illustrated in Fig. 4, and the rapid increase in swelling with rise of

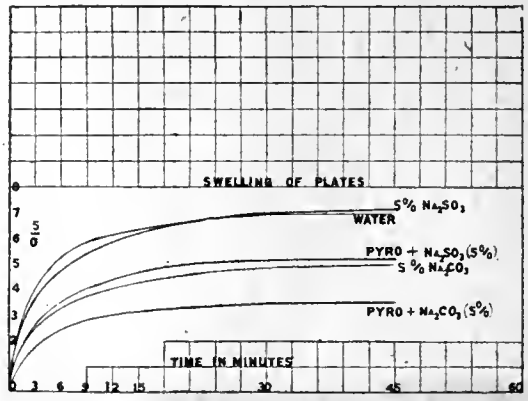

Fig. 8.—Rate of swelling of gelatino-silver-bromide emulsion.

temperature is shown in Fig. 5, in this diagram the abscissæ are molar concentrations of acid and alkali instead of p_H.

In considering the relation of such curves to the photographic

15. H. R. Procter and J. A. Wilson, J. Amer. Leather Chem. Assn., 11, 399 (1916).

process, it must be remembered that the plate or film is first placed in an ordinary alkaline developing solution, in which it remains, if *time* development is used, perhaps 5 minutes. If

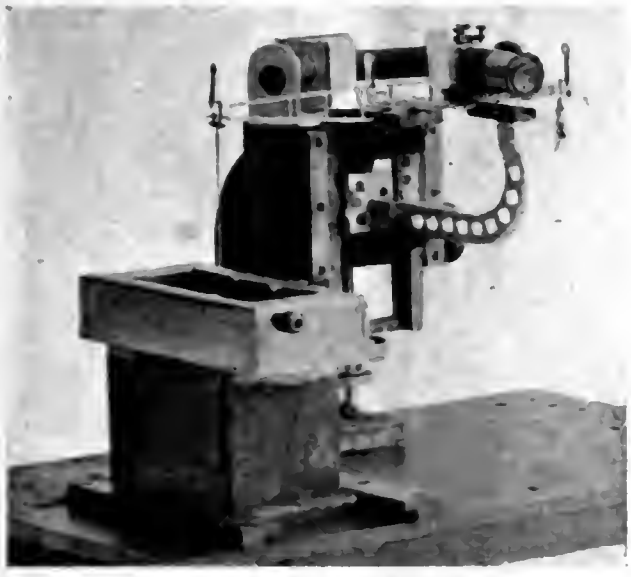

Fig. 9.—Auxometer for measuring thickness of gelatine film

stand development is used, it remains a longer time, say 15 to 25 minutes, in a much less concentrated developing bath. It is then rinsed in water and transferred, usually, to an acid fixing bath. The acidity of this is not very high (ph 4-5, see later), but in any case the gelatine has to pass back through the isoelectric point of minimum swelling. Before considering what effect such variations may produce, it will be well to note the order of magnitude of normal swelling with photographic films, and its change with time. Since under normal conditions the gelatine can only swell perpendicularly to the plane of the plate or film, the swelling can be measured either by weighing or by measuring the thickness. In fig. 6 is shown the rate of swelling of a photographic emulsion as followed by *weight* measurements.

In this case sodium carbonate solution was used, this being a generally used alkaline component of developers. In figs. 7 and 8 are illustrated the course of swelling of an emulsion in sodium sulphite solutions, and in a pyrogallic acid developer with sodium sulphite.

All these determinations were made by the weighing method. This procedure is time-consuming, and not applicable where it is desired to follow the progress of swelling simultaneously with an actual photographic operation—e.g., development. To accomplish this the writer has designed an instrument to measure the thickness at any stage. This instrument, which may be termed an *auxometer*, is illustrated in fig. 9. It consists of a micrometer carrying a delicate balance beam; at one end is a silica rod, with a small "foot," just in contact with the film surface; at the other a counterpoise. Any increase in thickness (swelling) throws this off balance, the deflection being optically magnified. Balance is restored by the micrometer screw, and the change in thickness read.

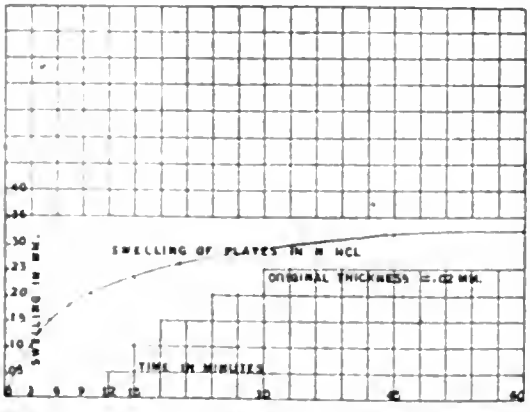

Fig. 10. Swelling of gelatino-silver-bromide emulsion in hydrochloric acid.

In fig. 10 is shown the swelling of a film in an acid solution.

S. E. Sheppard.

(*To be continued.*)

WHAT THE PUBLIC LIKES.

The late Lord Northcliffe's recipe for successful journalism is stated to have been: "Give the public what it likes, not what you think it ought to like." In one sense, this is genuine wisdom. In great fundamental matters the instinct of the multitude is usually right, rather than that of the individual.

In another sense, however, this formula has often been twisted into a wrong direction—that of judging popular taste by its more obvious faults and fallacies, as if these were common to all, rather than peculiar to a few. Photographers, in especial, have long been used to quoting this saying, as an excuse for mediocre work and a low artistic ideal. That is a bad mistake, and by no means a modern one. Back in the mists of antiquity, Cicero (*De Oratore*, Book III.) finds it necessary to warn his readers that, while the learned and illiterate may differ greatly in other things, they show surprisingly little difference in their judgment on points of artistic taste. In other words, "playing to the gallery" is a tactical blunder, even when the boxes and stalls are empty.

How, indeed, can the photographer actually be sure of what his public wants? His clients are not good at expressing their artistic likes and dislikes; their non-technical language often conveys quite a wrong impression of their true meaning. What they seem to object to in a portrait very frequently turns out not to be the real cause of complaint. Hence, in attempting to summarise and satisfy our public's requirements, in antagonism to our own prepossessions, we may merely follow strange paths that lead nowhere.

The fallacy of trying to propitiate the public by ruthlessly displeasing ourselves is beginning to be exploded. The remark of a salesman at one of New York's leading stores, after the exit of a particularly good purchaser, is piquantly relevant. "Any old fool," said he, "can sell a person what he fancies he wants; but the really clever man can load him up with a year's supply of what used to be his pet aversion! That customer is going to deal here again. If I had sold him to-day, what he thought he wanted, he would have consigned me to Hades to-morrow!"

It must always be remembered that a basically good principle can be worked with practical permanency, whereas a false one breaks down sooner or later—often with tragic suddenness. As the political axiom goes, "You can't fool all the people all the time." Unquestionably, it is trying to do so, to keep on giving an artistically-ignorant clientele work which we do not ourselves approve of, while making them believe that both we and they are satisfied.

The shapers of fashion are wiser. They do not trouble about the hypothetical likings of an imaginary public. They design to suit their own tastes, after more or less sound artistic canons, and say calmly: "This, and no other, is what will be worn." The tailor and the modiste supply things rigidly in accordance with this dictation, and the public unmurmuringly accepts.

Photographers, unfortunately, have no such uniform ideal. The majority, perhaps, may not unfairly be described as suspicious of the definitely artistic, and obsessed by the notion that most people prefer what may be called the picture-postcard and illustrated-newspaper style of portraiture, though mounted in a more select way and duly raised in price. That idea is no longer tenable, whatever it may have been in the past. Any attentive observer may satisfy himself that the studios which have been squeezed out through the prevailing difficult conditions are practically always those producing commonplace work.

In the principal thoroughfare of a certain London suburb, for instance, there were till recently three different studios. The output of one was cheap and of poor quality. The second, an old-established firm, gave "the usual thing"—that is, "hard and bright," somewhat over-retouched, a little stiff and formal in pose, mainly of a black tone, and very neatly mounted on "superior looking" mounts. The third studio made a distinct artistic appeal. The tonality of the pictures was soft, strength and vigour being secured simply by striking systems of lighting. Each portrait was characteristic. The prints varied in colour from sepia to a brown-black, the mounts were folders of subdued tint, in various unconventional types. The windows were handsomely panelled in oak, and the set-out altogether unlike the ordinary photographer's display. The prices, too, were slightly higher, though still reasonable considering the quality. Now, nine photographers out of ten would probably have felt certain that the older studio, with its compromise in ideals, would outlast the others. What actually happened is that the cheap firm went bankrupt first, next the old-established one closed its doors. The sole survivor, more prosperous than ever, is the firm that does *not* try to give people what they like, but makes them like what they are given.

Again, what is happening to the old type of ugly, staringly ornate furniture, which was supposed to be the only kind that would sell? It chokes up the various warehouses, and will doubtless end its days in seaside lodgings. Beautiful furniture, the quaint, the uncommon, that based on lasting principles, is selling now. The so-called stupid British public instinctively *knows*. For all its outward Philistinism, it is not nearly so obtuse and blatant as we are asked to believe.

A. Lockett.

COMMONSENSE RETOUCHING.

[A writer in the November issue of "American Photography" has some useful advice to give to the retoucher who is taking up the work for the first time. As he remarks, experience is most necessary, and it should be best for the beginner to practise his strokes upon some old and useless negative before attempting the true work. The previous pencil retouching on this negative should be cleaned off by the aid of a piece of cotton wool moistened with pure turpentine, and the negative thoroughly dried. It may then be re-coated with medium and the practice strokes attempted. A print should preferably be taken before retouching, and another from time to time as the work of retouching progresses. By this means the tyro will gain considerable knowledge as to the extent to which retouching should be carried, and he will be able to lessen or increase the quantity of his work to suit the particular portrait in hand. It should be borne in mind, however, that retouching is merely an aid in the obtaining of a good portrait, and should not be made use of to correct errors which have occurred in the studio. With the present-day possibilities of lighting which the operator has available, shadows and high-lights may be perfectly controlled, and the retoucher should only be called upon to soften lines in the resulting negative, or to make pleasant any awkward form or arrangement, which is beyond the studio operator's control.]

Retouching is an art that is comparatively easy of accomplishment. Not how to apply the lead, but where to apply it is the essential thing to know, and, for that reason, all teaching can be only general in scope. The ideal retouching pencil must contain a uniform, high-grade lead of constant quality. It should be obtainable in many degrees of hardness, at a moderate price and in convenient, non-fatiguing holders. To begin with, about four pencils will be all that are needed—hard, medium hard, medium soft and soft. Other leads, probably, will accumulate as time goes on and experience ripens, the best grade to use in any particular instance can only be ascertained by experience. Information that will be neither confusing nor liable to misuse is that the lead which blends with the surrounding parts of the negative is the one to be selected, and the heavier the deposit on the negative the softer will be the lead required to match it in density. An etching knife is a necessary part of the retoucher's equipment. This may be a shaped and sharpened darning needle, an etching pen, used with an ordinary pen-holder as a handle, or a well-sharpened penknife. A knife is very useful for removing unnecessary high-lights, such as, for instance, lights reflected by buttons, jewellery or eyeglasses. For reducing larger areas one of the many forms of abrading implements, such as the "hi-lite" reducer, made of fine strands of spun glass, is better than a knife and is easier to manipulate. The art of using a knife is harder to master than the use of the pencil, yet it is an accomplishment that should be learned, as it is of inestimable value, and considerable practice is needed before the user becomes really expert. The knife should be held so that only the surface of the negative is touched and the emulsion should be shaved very lightly. The knife must not scrape or drag, or the work will be uneven, a little careful practice on an old negative being necessary to get the required action. India ink and spotting colours are needed to fill in pinholes and deep scratches, and these are usually applied to the negative with a fine "spotting" brush. If a pen point is used as the means of application, great care must be taken to avoid damaging the fragile emulsion beyond repair. "Opaque" is very useful for "blocking out" objectionable backgrounds. Often a subject will stand out with a new value and be much more convincing if the print is made with a complete absence of background. This effect is easily secured by "opaquing" the negative up to the outer edge of the subject, the resulting print showing the subject against a clear white background. This is usually necessary in commercial work, with machinery, and other subjects where clear detail is required. It needs considerable patience and a steady hand. Sometimes the opposite effect is desired; a black background instead of a white one. This effect can be obtained by etching away the background. Some kind of retouching medium is needed, which is to be rubbed on to the negative, where it dries quickly, leaving a fine hard surface that is ideal for the easy application of the retouching lead. This medium at the same time protects the emulsion from abrasion and from the attacks of insects.

To secure sufficient transmitted light it is necessary to support the negative in some manner close to a window. Daylight, however, is not altogether satisfactory, because it is constantly varying. The problem of proper illumination is best solved by using a retouching stand lighted by an electric bulb, the direct rays of which are softened and diffused by a piece of ground glass interposed between the negative and the light. The ground glass should not be very close to the negative, or, if it is, it should be placed smooth side up, otherwise the grain may be too plainly visible and may interfere with the pencil work. If daylight is utilised as the means of lighting the negative, a north light should, if possible, be used, as it is far less variable than any other. The mirror supplied on the commercial retouching stands is not nearly as good a reflector as a large square of white cardboard. There are many so-called "strokes" and "touches," each retoucher having his or her favourite. Four of the most common strokes are illustrated, each being, necessarily, much exaggerated.

Stipple. Crosshatch. Figure eight. Blending.

One of the first questions asked by the novice is: "What stroke shall I use?" and this is a hard question to answer. The average retoucher uses many "strokes," and variations and combinations of them, the best being the one that covers the area most quickly and with the smoothest effect. Every worker will have his own idea as to the amount of work a negative requires, but, as a general rule, much of the ordinary commercial work is over-retouched. It is very seldom that a patron desires a portrait so much smoothed out that there is no difference between the face and the neck, or "cleaned up" to such an extent that there are no separate tones in the numberless light-planes of the face, head and cheeks. The usual portrait can be divided, broadly, into four "zones," each being sub-divided into further zones. The chief divisions are the

face, the bust, the hands and draperies The forehead is a surface that is made up of a number of light-planes. Wrinkles may be removed entirely or merely softened. Dark circles under the eyes and the "crows' feet" at their corners should be eliminated. On the pupil of the eye there should, usually, be a triangular high-light. If this be round or bead-shaped, it will impart a lifeless stare and give the portrait an unnatural appearance. Eyebrows may be arched a little or may be softened, if they are too dark, by the careful application of the pencil. A crooked nose will be straightened, as if by magic, when the shadows at the side are lightened or evened up. Flat nostrils can be given a better appearance if a slight high-light along the ridge is introduced by careful pencil work. Hollow cheeks, or cheeks in which a healthy, red colour has come out too dark in the photograph, may be filled out by retouching, but here caution must be exercised, for if it is overdone a "heavy" look is imparted to the subject. Receding chins may be built up, by the simple expedient of lightening the upper part a little. A small shadow, just under the lower lip, produces the illusion of greater depth and roundness of the entire face. A shadow should always be visible between the neck and the jaw. Squaring up the latter and adding a high-light to the "point" will give the subject a forceful individuality. In portraits of ladies, if the neck appears "bony," the artificial aid of retouching may be called into service.

Many instructions have been given in connection with the manipulation of the subject's hands. Beautifully posed hands are rare. They are hard to manage, and to make them appear graceful and at the same time natural is one of the problems of portraiture. If the veins are over-emphasised, retouching will help. Sometimes it is necessary to reduce them a little in size by the careful use of the etching knife.

Draperies that are light in colour may need a little local reduction. Any of the specially-prepared reducing pastes, or a piece of cotton wool, moistened with alcohol, used as an eraser, will much improve the print. Sometimes the use of the knife is necessary to improve outlines. As a general and very broad rule, it may be stated that in portraits of ladies under thirty all lines and wrinkles may be removed. Over this age, the objectionable "footprints of time" may be eliminated and other character lines softened as much as may be considered necessary. Portraits of men usually require very little actual retouching, only a general "cleaning up" and softening of too aggressive shadows. The best advice anyone can offer to the tyro is, use sane judgment, practise constantly, and study all the time.

It must not be forgotten that much of the retouching, once thought to be imperative, may be eliminated by skilful and intelligent lighting, by careful focussing and by the use of a suitable lens.

J. De Witt Kalfs.

FORTHCOMING EXHIBITIONS.

December 9 to 31.—Rochdale Amateur Photographic Society. Particulars from the Hon. Secretary, W. Lord, 10, Derwent Street, Rochdale.

1923.

February 5 to March 3.—Northern Photographic Exhibition, City Art Gallery, Manchester. Latest date for entries, January 12. Particulars from the Hon. Exhibition Secretary, Walter Johnson, 30, Hartington Road, Chorlton-cum-Hardy, Manchester.

March 1 to 8.—Birmingham Photographic Society. Latest date for entries, February 15. Particulars from the Hon. Secretary, J. E. Breeze, 178, Broad Street, Birmingham.

March 2 to 31.—Pittsburgh Salon of Photography. Latest date, February 5. Secretary, Charles K. Archer, 1,412, Carnegie Building, Pittsburgh, Pa., U.S.A.

March 13 to 16.—Exeter and West of England Photographic Exhibition. Particulars from the Hon. Secretary, Frederic G. Tutton, 9, Union Road, Pennsylvania, Exeter.

March 15 to 24.—Photographic Fair, Holland Park Hall. Secretary, Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

Owners of Photographs Wanted.—It was stated in last week's newspapers that over 100 photographs—mostly of soldiers killed in the war—are in the possession of the police at Hendon awaiting identification. They were discovered at a house in Carlton-vale, Kilburn, occupied by a man who was remanded at Hendon on a charge of obtaining money by false pretences.

Patent News.

Process patents—applications and specifications—are treated in "Photo Mechanical Notes."

Applications, October 30 to November 4 :—

Dark Slides.—No. 29,630. Photographic dark slides. P. C. Bull and K. C. D. Hickman.

Reflex Cameras.—No. 29,970. Photographic reflex cameras. A. J. Denniss, W. Dockree, and Houghton-Butcher Manufacturing Co., Ltd.

Cinematography.—No. 29,766. Liquid treatment of cinematograph films. J. M. Andrews, J. A. Ball, Technicolor Motion Picture Corporation and L. T. Troland.

Cinematography.—No. 29,840. Cinematographic film. A. L. V. C. Debrie.

Cinematography.—No. 29,976. Apparatus for coating cinematographic, etc., films. E. Robertson and L. M. Wyllie.

Colour Cinematography.—No. 29,764. Colour cinematograph films. Technicolor Motion Picture Corporation.

Colour Cinematography.—No. 29,629. Manufacture of multi-colour screen films, or plates for colour cinematography. J. Camiller and A. Hay.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country, or abroad, in the case of patents granted under the International Convention.

Camera for While-you-wait Postcards.—No. 166524 (July 13, 1920). The invention relates to a photographic camera having provision for developing and copying negatives, in which the image is focussed, and the developing, fixing, etc., of negatives and positives can be carried out inside a portion of the apparatus which constitutes a dark box. The camera is provided with a sliding bellows frame having a negative holder attached, enabling positives to be produced by means of a lens from negatives previously obtained in the same apparatus. In this camera a carrier frame for negatives or positives, and a focussing screen holder, are permanently and interchangeably mounted inside a box extending from the rear of the camera in such a manner that the focussing screen can be placed in position behind the objective without removing the carrier frame from its point of attachment and *vice versa*. This arrangement of the focussing screen and carrier frame in the interior of the dark box makes it possible to work with precision inside the box rapidly and unhindered.

The dark box is provided inside with receptacles for containing a supply of photographic cards or papers, capable of being opened and closed inside the box. The end of the wire which actuates the lens shutter is passed into the interior of the box. These fittings enable a continuous, and consequently rapid, mode of working in the interior of the box, commencing with the insertion of the sensitised paper or card, until the printing has been finished. A sliding copying arrangement is provided for producing positives from negatives; the carrier frame for the negatives can be swung up or folded down, and is only set up when required. In the accompanying drawings the sliding frame C of the apparatus has mounted upon it an objective carrier D, capable of being displaced and fixed. In the objective carrier a frame D^1 with an objective E (preferably of high rapidity and short focal length, and having a time and instantaneous shutter F attached) is mounted so as to slide up and down.

The objective frame D^1 is connected by a bellows B to the box A. The box consists of a base A^1 of the wall K for receiving the movable carrier frame K^1 and the focussing screen holder J, the two side walls L, the upwardly opening door T and the lid R, which contains a ruby-red transparent plate R^1. The sleeves M are attached by rubber bands or springs to the arms of the operator to prevent the entrance of light, and open into the side walls L. Troughs 1, 2, 3 are fitted in the base A^1, and may be slid in or suspended therein in a light-tight manner, preferably by being contained in a common trough O, which is suspended in the base. Spectacle glasses 9 of ruby glass are

fitted in the door T. From the shutter U an antinuous release V with a press button W passes into the interior of the box. In the wall K the carrier frame K^1 and the focussing screen J are mounted and are interchangeable. The carrier frame K^1 is mounted on the wall K so as to be capable of swinging laterally about the hinge 15 (fig. 2). The carrier frame K^1 consists of two parts K^{11} and K^{111} between which the sensitised paper is placed and clamped round its edges by fastening down the part K^{11} on the part K^1. The focussing screen J is mounted on the wall K, and is capable of swinging on the hinges 16. By this means either the focussing screen J or the frame K^1 can be brought behind the objective E, according to whether the objective is to be focussed on the subject or by inserting a sensitised card, a negative or positive is to be produced. Where there is space on the camera walls, receptacles 6, 7, for photographic papers or cards for negative or positive purposes are fitted.

In front of the objective frame D^1 on the slide C a copying extension part H is mounted. The copying frame F, which is

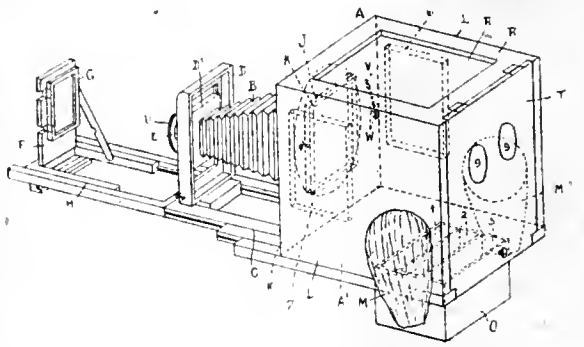

Fig. 1.

hinged and can be erected on it, carries the frame G for the reception of a negative. The negative is illuminated by reflected light either natural or artificial, and the objective E is focussed on this negative, which may be effected by simply pushing out the frame H. If a number of positives are to be made, they can be finished separately or they can be stored in the containers 6, 7, and subsequently developed one after another, and so on, so that the person ordering the photographs can take them away with him at once.

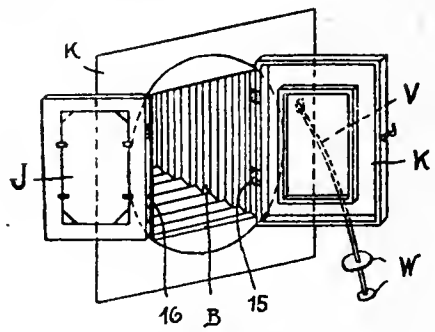

Fig. 2.

When an exposure is being made, the removable frame K^1 is swung open, the sensitive material placed in it, the focussing screen J swung away, and the frame K^1 swung to again, so that it takes the place of the focussing screen. In the interior of the camera A, by a pressure on the knob W of tho antinuous release V, the objective shutter U is opened and closed as required, for a time or instantaneous exposure. The exposed negative is removed from the frame K^1 by means of a clip, placed in the developing trough 1 and developed while being viewed through the spectacle glasses, the requisite illumination of the interior of the camera being obtained through the red window R^1, or a red lamp inside the camera. After the development is finished, the exposed plate is placed in the water trough 2, when it is passed, after being washed, to the fixing trough 3. For reproduction purposes, the copying extension H is pulled out, the copying frame F at the end of it is erected vertically, and the frame G on it opened.

The door T of the camera A is thereupon opened, and by means of a clip the negative, which has in the meantime been fixed, is taken out and can be mounted while still wet in the copying frame G, after which it is reproduced in the ordinary manner. The positive obtained by this means is removed from the frame K^1 and developed, washed, and fixed in the same manner as the negative.—Wilhelm Feuerzeug, 30, Brigittenauerlände, Vienna XX., Austria.

New Materials.

Christmas Greeting Mounts and Calendars. Made by Bartons', Finch Road, Handsworth, Birmingham.

Although we have long been familiar with the highly artistic mounts of Messrs. Bartons', and have admired an invariable good taste in the design of these requisites, we cannot remember having seen hitherto mounts of theirs intended for the transmission of Christmas greetings. A selection of these, which Messrs. Bartons' have sent to us, shows the same nice discrimination in the use of papers and boards of the most agreeable tints and textures. The mounts are of the folder pattern, and most of them for the attachment of prints by pasting down or by attachment at two corners. One or two, however, are of the slip-in pattern. While it would be invidious to name as specially pleasing any of these productions, we may signalise one or two. The "Valdena" is a folder, made in sepia or grey, for cabinet prints pasted down on a plain tint of suitable colour. The price is 3s. 3d. per dozen, or 36s. per gross. Another very choice little mount is the "Rothney," for prints measuring about $3\frac{3}{4}$ x $2\frac{1}{2}$ inches. It is made in brown or white and is priced at 1s. 9d. per dozen, or 18s. per gross. Another tasteful folder for postcard portraits is the "Baronic," obtainable in brown or grey at 2s. per dozen, or 20s. per gross. Messrs. Bartons' likewise are offering for the forthcoming season a number of equally attractive calendar mounts for prints ranging in size from V.P.K. to postcard, and in price from 4s. 6d. to 6s. 6d. per dozen, or 48s. to 72s. per gross. Here, again, choice is offered between the paste-down and slip-in patterns. The calendars are provided with silk tasselled cords, and may be had either upright or landscape in shape. Photographs mounted on any of the productions before us form most artistic and acceptable Christmas gifts.

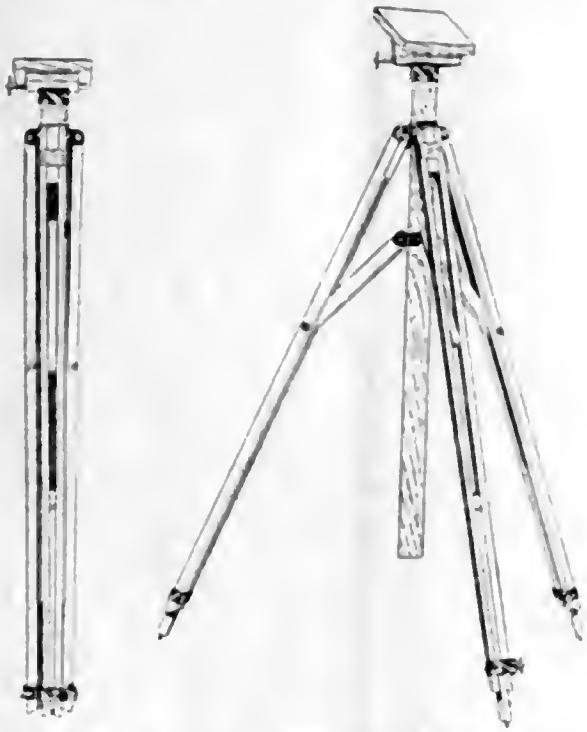
Sedar Guilleminot Bromide Paper.—This paper, which is manufactured by the Guilleminot Company, of Paris, combines a printing medium of undoubted excellence, with sufficient speed to allow of enlargements being made with a minimum of exposure. The paper is supplied in three surfaces—matt-smooth, semi-matt and glossy—and is coated upon either single or double weight base, no extra charge being made for the latter. The sample of the paper which has reached us is of the semi-matt variety, and we have made prints by both contact and enlargement with the idea of testing the general qualities of the printing medium. By contact, using a portrait negative of average density and a 50-c.p. lamp at 4 ft. distance, we obtained fully-exposed prints in ten seconds, which upon development gave perfect gradation and good density, the image being of fine black colour, full of life and sparkle. The semi-matt surface, which closely approximates to the surface of a carbon print, gives considerable luminosity to the shadows. In enlarging, we found the paper of good average speed. Upon development we obtained the same high quality of print, showing perfect high-light detail and fine luminous shadows. Using the borax-metol-hydroquinone developer, slightly warm-black tones were obtained, quite pleasing in colour and of good density. The paper is undoubtedly of very high quality, and we strongly recommend our readers to test it for themselves. Free testing samples are supplied to any *bona fide* professional photographer upon application to the London agent of the company, M. Jules de Gottal, 17, Cecil Mansions, Marius Road, London, S.W.17.

East Anglian Photographic Federation.—The annual meeting of this Federation was held at the Headquarters of the Cambridge and District Photographic Club on Saturday, November 4. The Federation is in a very flourishing condition, the number of clubs affiliated now being 100 per cent. more than in 1915. It was decided to hold the annual meeting and exhibition at Peterborough next year, and the annual combined excursion at Cambridge on Whit Monday. Mr. Edward Peake was elected President, and Mr. W. Farren, 76, Regent Street, Cambridge, Secretary and Treasurer.

New Apparatus.

The Korona Folding Studio Stand. Sold by Sands, Hunter and Co., Ltd., 37, Bedford Street, Strand, London, W.C.2.

For the purposes of the photographer who has to do work of any kind away from the studio, whether home portraiture or such commercial photography as the copying of paintings in picture galleries, a firm yet light stand for the camera, which can be conveniently used on polished floors, is a *sine qua non*. The requirements of the practical worker are most admirably met in this stand, which is exclusively supplied by Messrs. Sands, Hunter. One notable feature of the stand is the triple strut or stay which holds the three legs firmly in position and thus allows of the stand being moved about on a level surface without disturbing either the height or the level of the camera itself. Nobody who has used an ordinary tripod, say, for photographing pictures or for other copying work, will forget the immense amount of trouble that has to be taken in order to get one subject after another nicely placed and focussed. Probably more time is wasted in this branch of work by the use of the customary type of tripod than in any other way. Moreover, the three strut bars give extraordinary rigidity to the stand, so that it may be used, not only for cameras



but, in the larger of the two sizes in which it is made, as a support for a projection lantern of moderate size. A further excellent feature of the stand is that the central supporting pillar, which is of triangular section, is given a vertical sliding movement. By the operation of two set screws the camera may be lowered from its maximum height of 5 ft. to just over 3 ft.; and by a further spreading out the legs or drawing them in, a somewhat lower or higher position may be obtained.

The stand is exceedingly well made in cherry wood with non-tarnishable metal fittings. In the smaller size its weight is 4 lbs. in the larger, 6 lbs. The smaller size, which is recommended for cameras up to half-plate in size, is priced at £3. For cameras of larger size the No. 2 stand is recommended; its price is £3 10s. These prices include a detachable head, which takes the form of a tilting table, by which the camera may be inclined at any angle up to about 40 deg. Further tilting in any direction may be obtained by means of the sliding portion of each leg. Altogether the piece of apparatus is one which will render any photographer long and useful service in all descriptions of work done at such a distance from the studio that it is impracticable to make use of the heavy pattern of stand commonly employed for studio cameras.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK

Monday, November 20.

Birmingham Phot. Art Club. "Composition." F. Smyth.
Bradford P.S. "The Making of a Lantern Slide." W. Bartle.
Dewsbury Phot. Soc. Members' Lantern Evening.
Forest Hill and Sydenham Phot. Soc. Print and Lantern Slide Competition.
Glasgow and West of Scotland Amateur Phot. Assoc. "The Process and the Exhibition Print." J. W. McKissack.
Kidderminster and District Phot. Soc. "Through Shakespeare's Country." Messrs. W. Butcher.
Southampton C.C. "Amateur Photographer" Prize Slides.
Walmsley Amateur P.S. "Holiday and Outings," 1922, Pictures.
Wallasey Phot. Soc. "The Chemical After-treatment of the Bromide Print." A. H. Redman.

Tuesday, November 21.

Royal P.S. "Astrological Portraiture." Alvin Langdon Coburn.
Birmingham Phot. Soc. General Meeting.
Bournemouth Camera Club. "Architecture and Architectural Photography." R.P.S. Lecture.
Burnley Mechanics' Institution Camera Club. "Hints to Beginners." F. Simpsons.
Cambridge and District Phot. Club. "An Egret Heronry in Andalusia." W. Farren.
Exeter Camera Club. "The New Forest." G. T. Harris.
Hackney Phot. Soc. "Health and Happiness in the High Pyrenees." Dr. C. Atkin Swan.
Leeds Phot. Soc. "Elementary Principles of Art applied to Photography." A. Keighley.
Maidstone and District Phot. Soc. "Psychology in the Studio and the Making of Portraits." C. P. Crowther.
Manchester Amateur P.S. "'Ilford' Lantern Plates." A. Brooker.
Morley Amateur P.S. "Making Lantern Slides." H. Walsh.
Nottingham and Notts P.S. "The Norfolk Broads." J. Sewell.
Portsmouth Camera Club. "Warm Tones by Development." Messrs. Wellington & Ward, Ltd.
South Glasgow Camera Club. "Auld Reekie."

Wednesday, November 22.

Birkenhead Phot. Assoc. "'Ilford' Plates and How to Use Them." A. Brooker.
Borough Polytechnic Phot. Soc. "Psychology in the Studio." C. P. Crowther.
Croydon C.C. "The Photographer and the Plate." C. M. Thomas.
Partick Camera Club. "The Chemistry of Developers and Development." W. M. Gregory.
Photomicrographic Society. Members' Evening.
South Glasgow Camera Club. "Development." W. W. Morrison.
South Suburban and Catford Phot. Socs. Discussion on Developers. P. B. Salmon.

Thursday, November 23.

Coatbridge Phot. Assoc. Print Night.
Edge Hill Camera Club. "Collected Notes on Pictorial Photography." J. R. Charlton.
Gateshead and District C.C. "Old English Monasteries." C. Young.
Hammersmith Hampshire House Phot. Soc. "Art and Photography." F. Judge.
Kinning Park Co-op. Soc. Camera Club. Scottish Photographic Federation Portfolio.
Letchworth C.C. "Nature and the Lens." A. R. Thompson.
North Middlesex Phot. Soc. "The Fascination of North Africa." C. H. E. West.
Richmond Camera Club. "Colour Slides." F. R. Newens.
Rochdale Phot. Soc. "Combination Enlarging." J. C. Wild.
Sun Camera Club (London). "The Story of the 'Cuckoo Spit.'" Dr. Geo. H. Redman.
Wimbledon and District Camera Club. A.P. & P. Prize Slides.

Friday, November 24.

Royal P.S. "The Fascination of North Africa." C. H. E. West.

Saturday, November 25.

Edinburgh P.S. Opening of Members' Exhibition. Social Evening.
Hackney Phot. Soc. The Lea Valley. W. Selfe.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, November 14, Dr. T. Slater Price in the chair.

The meeting was under the control of the Scientific and Technical Group of the Society, and papers were read by Messrs. K. C. D. Hickman, D. Norman Lawrie, and Mr. Rawling, on behalf of Mr. J. C. Keighley, who was not present.

The first paper concerned some experiments upon the tensile strength of gelatine and gelatine jelly, which had been made by Mr. Keighley, but, owing to the absence of the author much [illegible] concerning the results obtained was lost. However,

the results obtained in the experiments conducted upon jellies of known strengths were remarkable in showing a constant ratio in direct proportion to the square of the concentration. This was with jellies cast in 15 mm. tubes, but with dried gelatine from known strength jellies, the breaking load was not in so direct a proportion. In testing the latter types of gelatine, an ingenious method was shown. The jellies of known strength were poured while warm upon glass plates, and were then dried. The gelatine was cut into narrow strips upon the glass, and each strip attached to a small wooden handle. A loop was made at the other end of the strip, and here were attached the various weights, which were added to until the strip of gelatine ultimately broke. An interesting point was mentioned in connection with the soaking of dried gelatine in water. It was at first thought that heat would be absorbed, but this was found to be quite wrong, heat being actually evolved in the process. When 16 gms. of gelatine were placed in 250 gms. of water it was found that a total increase of temperature of .8 deg. C. occurred in 30 minutes, but this varied with different specimens of gelatine. In the discussion which followed Dr. Slater Price said, the author of this paper would have saved himself much work if earlier literature upon the subject had been consulted, but he was to be congratulated upon the simple manner in which he had explained and presented the results of his experiments. A hearty vote of thanks was accorded to Mr. Kingdon for his paper, and to Mr. Rawling, who had read the abstract.

Mr. K. C. D. Hickman then delivered his lecture upon rapid sulphiding of bromide prints. Mr. Hickman said the process he was now presenting was not a new one, but, perhaps, his method of working it was an improvement upon that which had been previously attempted. Of bromide toning processes in general the lecturer said that only one was of value to-day, and that consisted of darkening a bleached image with a sulphide. The other processes consisting of depositing metals, etc., upon the silver image had been given up, and the public now wanted only a good, cold sepia, such as the sulphide process, properly worked, would give. The lecturer discussed at some length, and with the aid of lantern slides, the cause of greenish-black images in bromide prints, and he explained that images of this kind gave very weak yellowish sulphide tones. It was therefore necessary to obtain, first of all, a good black deposit of silver, and this was only obtained by correct exposure and full development of the print. Mr. Hickman explained that halogen salts, as generally used in bleaching baths, were slight solvents of the silver image, pointing out that silver bromide was slightly soluble in potassium bromide solution. This fact accounted for a slight weakening of the high-light detail often found in toned prints, and it was with an idea of preventing this weakening that experiments with halogen gases were made. In the earlier experiments a damp bromide print was placed in a dish covered by a large sheet of glass. Bromine vapour was blown into the dish, and the print quickly bleached. The glass lid was then removed and the bromine vapour blown away. The lid was replaced and sulphuretted hydrogen in the form of the gas was then allowed to enter the dish. The bleached image immediately darkened and a fine tone resulted. But this process was of no practical value on account of the penetrating fumes of bromine and the noxious smell of the sulphuretted hydrogen. A type of apparatus which was next evolved, and which was exhibited on the table, consisted of a box having glass sides and a ventilation tube. This tube contained a gas jet, and by creating a current of heated air relieved the compartment of unused vapours. The experiments in which bromine was used proved that this substance was useless for the process owing to its power of attacking gelatine, and also to the fumes, more particularly of the atomic bromine liberated, which made the process unbearable. An interesting experiment was explained, in which coal gas was used to drive the hydrogen sulphide into the chamber. As a gas jet was burning in the ventilation tube, and gas and air allowed to enter the toning chamber, it could be quite understood that sooner or later an explosion would occur. This actually happened, and Mr. Hickman then decided to change the method and the substances used. Chlorine was used and was found far more satisfactory. A water driven ventilating fan was attached to the chamber, and the fumes were easily drawn off and dispersed without inconvenience to the worker. The bromide prints were first damped in water and blotted. They were then hung by celluloid clips upon glass rods, which were placed inside the chamber, and the glass lid fixed down. The chlorine was then blown in and the damp prints bleached very rapidly. The fan was then started and the lid of the box lifted to allow air to enter. After a few minutes the lid was replaced and the sulphuretted hydrogen blown in by means of carbon dioxide. The prints darkened at once, and gave good even tones of a cool sepia colour. A drawing of a new type of toning machine for cinematograph films by means of the above process was shown upon the screen, and its possibilities explained. In the discussion which followed, Dr. Slater Price said that it would be found that chlorine attacked gelatine nearly as strongly as bromine, so that care would have to be exercised in the bleaching of the film. A hearty vote of thanks was accorded to Mr. Hickman for his interesting lecture.

Mr. D. Northall-Laurie then proceeded to show upon the screen some interesting slides of chemicals and various sections made by means of the microscope upon Paget colour plates with polarised light. The lecturer had devised a method of showing the beautiful colours obtained with a polariser, actually changing upon the lantern screen. The device used consisted of a wooden slide, in which the positive image plate is mounted stationary, but the colour filter could be moved slightly over a small area either forward or backward by means of a screw. The results were very beautiful, and much admired by the audience. Mr. Northall-Laurie was heartily thanked for his lecture and for showing the results of his work, which, said the chairman, would be of great use when instructing students in both the use of the polariser and in connection with chemical crystallisation.

EDINBURGH SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.

Meeting held on Monday, November 6. Present: Mr. J. Campbell Harper, Mr. George Balmain, Mr. George Ayton, Mr. W. B. Hislop, Mr. A. J. Hughes, Mr. Fergnason, Mr. John Thomson, Mr. Norman Thomson, Mr. W. J. Hutchieson, Mr. J. R. Coltart, and Mr. E. D. Young. Mr. J. Campbell Harper, the President, in the chair.

It was reported that the class for practical chemistry and optics had become defunct, owing to lack of studenta. This information was received with regret, as the class had acquired a considerable amount of success last year under the able tuition of Mr. Hislop.

It was resolved to postpone the holding of the annual dinner of the Society, which is usually held on the first Monday in December, until the apring. It was suggested that it might be held during the proposed exhibition in March. The President proposed, with the view of getting the assistants better acquainted with the objects of the Society and the membera interested in them, that a social evening and whist drive be held in January, to which all the assistants in the employment of membera would be invited. This was unanimously agreed to, and Mr. John Thomson, Mr. George Balmain, and Mr. Wm. Fergusson were appointed a committee to make the arrangements.

The rates for supplying electric current for power to professional photographers was next on the agenda, but as the evening was so far advanced it was agreed to delay discussion until next meeting. The President pointed out that before they could approach the Corporation authorities it would be necessary to get definite information as to what concessions professional photographers in other towns obtained from their Corporations. Mr. Hislop mentioned that he had been informed that until the new power station was ready and in full swing the Corporation would not consider the granting of any concession, as the electrical power was needed for other purposes.

CROYDON CAMERA CLUB

The Annual Dinner at the Greyhound Hotel proved to be the usual enjoyable function, a large number of members and guests turning up. With speeches at the minimum (excepting one oration) and good cheer at the maximum, all was well indeed.

After the loyal toast, a silent one was offered to the memory of a departed comrade, Mr. H. T. Dodsworth, an ex-President, who in the past worked hard for the club. He is sadly missed. The President, Mr. John Keane, in proposing "The Visitors and Press," alluded gracefully to the cheery Mr. A. C. Brookes, and wished him all success in his new venture at the Holland Park Rink. Mr. Tilney he referred to as the finest art critic in photographic circles, and all, he said, would welcome Mr. S. Bridgen, the hard-working chairman of the Affiliation. The unavoidable absence of the "Walrus" and other old friends was much to be regretted. On the other hand, they had the pleasure and gratification of again having among them the editor of the most important photographic paper in the world—Mr. Geo. E. Brown. Unanimously the Council had decided to ask him to accept an honorary life membership of the club. (Loud applause.)

Mr. Brown, in reply, said he could not sufficiently express his feelings for the honour done him, and immediately followed

with a more than adequate elucidation. The secret of the club, he continued, baffled time, it being based on perpetual good-fellowship, which nothing could extinguish. In fact, he regarded the club as one of the healthiest things existing in the photographic world. He regretted the absence of Mr. Child Bayley, who was in America. Doubtless many had noticed, without guessing the cause, that the *Aquitania* had recently been delayed in transit across the "pond." Mr. Mortimer, he understood, had started pigmenting a Bromoil, and thus was unavailable for an indefinite period.

Mr. Tilney, looking as sober as a judge, stated he was submerged, but soon rose to the surface and contributed an amusing speech. As did Mr. Bridgen in parts. Much too solid information, however, was afforded about the past, present, and future of the Affiliation, which is expanding and prospering. Obviously a kind personality, and on this his first visit, all was forgiven him.

Then came a surprise presentation to the President, on which hangs a tale. Some little while ago, in one of the club's reports, a not altogether flattering allusion was made to his latest pipe of peace. Shortly afterwards the Secretary, Mr. Sellors, received through the post a really beautiful specimen, and, thinking it was a present from some rich relative, felt highly "bucked." A perusal of an anonymous letter enclosed in the parcel came as a sad damper, for the generous donor requested that the pipe be presented to the President for the sake of the lesser lights compelled to sit in his vicinity. Evidently it was overlooked that any benefit derived from the abatement of an undoubted nuisance will be counterbalanced by the creation of sinful feelings of covetous envy. But, given a sufficient number of readers of the *B.J.* filled with the same charitable instincts, the incident seems to open out delightful possibilities for the future. The thing will, of course, require delicate handling to avoid suppression by editorial powers that be. Needless to say, Mr. Keane expressed surprise, etc., and many thanks to the unknown donor.

In the entertainment line the singing of Miss Cecil Lucas was a real joy. Possessed of a glorious contralto voice, a successful future seems assumed. Mr. Godwin Bennett's fine tenor was another treat. Mr. Tayler's poison-gas contribution on the gazoophone, unhappily, will not readily be forgotten. Merry and bright as a drum-and-fife band was Mr. Kelfer's contribution. Mr. Tilney's cultured and sympathetic baritone voice was hardly at its best in a comic song, but he prospered, as did Mr. Ackroyd in a topical ditty. In orthodox adoring style Mr. Green rendered a love plaint in which "the stars grew cold and grey"—the right romantic spirit if a little inaccurate in celestial details. Mr. Harpur also loved someone "with a love that cannot die," and incidentally demonstrated the structural stability of the building. Altogether a most enjoyable evening.

Commercial & Legal Intelligence.

EASTMAN KODAK COMPANY.—The directors have declared the following dividends, payable to stockholders of record on November 20:—Extra dividend of $0.50 per share of common stock payable December 30, 1922; regular dividend of 1½ per cent. on preferred stock payable January 2, 1923; regular dividend of $1.25 per share of common stock, payable January 2, 1923.

CHRISTMAS MOUNTS.—The sample set of Christmas mounts for postcards which reaches us from Messrs. Jonathan Fallowfield, Ltd., 145, Charing Cross Road, London, W.C.2, are of extremely good design and quality. Made in various thicknesses of card and with tasteful combinations of tints, they should prove a good attraction for the Christmas trade. The mounts have various greetings embossed upon the front cover, and some have, in addition, small sketches and designs. The sample set of these mounts, comprising twelve patterns, is supplied to professional photographers for 2s. post free. As an addition to the above series, Messrs. Fallowfield are supplying a series of larger calendar mounts for postcard prints, all produced in the same excellent style. These mounts are of high artistic quality, while the calendars attached are of ample size. Four patterns are supplied in this series, and a sample set, containing one of each pattern, may be obtained for 2s. post free.

News and Notes.

ISLINGTON PHOTOGRAPHIC SOCIETY.—It is proposed to form a photographic society for Islington and Holloway, and persons interested are asked to communicate with Mr. Len Balston, 30, Ashley Road, Crouch Hill, N.4.

ALDERMAN FREDERICK SPALDING, head of the firm of Frederick Spalding & Sons, High Street, Chelmsford, has been elected Mayor of that borough. Mr Spalding has been a member of the Chelmsford Town Council for over thirty years, and is to be congratulated on the honour done to him by the representatives of his native borough.

ECLIPSE PHOTOGRAPHS.—The October issue of "Harringtons' Photographic Journal" contains reproductions of some excellent photographs of the recent eclipse of the sun as seen from Stanthorpe, Queensland. Two photographs, each taken on a Wellington Anti-screen plate, with a K2 filter, show the corona at its best. The exposures were made by Mr. W. Kimbel, of the Sydney "Sun" newspaper.

THE CAMERA CLUB.—The winter session of the London Camera Club, in addition to including a series of weekly lectures on many subjects of interest, comprises also demonstrations of photographic processes, and also a continuous sequence of house exhibitions in the lounge of the club at 17, John Street, Adelphi, London, W.C.2. That for the present month is of portraiture by Mr. N. E. Luhoshey. Tickets of admission to view the exhibition may be obtained on application to the hon. secretary, Mr. Robert M. Cocks.

QUICK METHOD OF MAKING BLUEPRINTS.—In places where the facilities for making blueprints are lacking, the following method (says "Popular Mechanics") can be used to produce satisfactory results: Instead of making the original drawing on tracing cloth, use a piece of paraffined tissue paper, which is backed up with a piece of new carbon paper. The waxed paper is placed over the carbon, so that pencil marks on it will be intensified by the carbon reproduction on the underside. The sketch is made in pencil, and the lettering can be printed in on a typewriter, still using the carbon. When finished, a print can be made from either the sketch intensified by the carbon backing, or from the carbon sheet itself. Blueprints made from the sketch will show white lines on a blue background, while prints made from the carbon copy will have a blue line on a white ground.

Correspondence.

*** *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

*** *We do not undertake responsibility for the opinions expressed by our correspondents.*

DARK ROOM LIGHT FOR BROMIDE PAPER.

To the Editors.

Gentlemen,—I was much interested in Messrs. Ilford's contribution to the correspondence under the above heading, as it confirms a [illegible] I have long held that some bromide paper is appreciably colour sensitive.

Some time ago I was testing the illumination of a dark room having direct light from a Wratten "O" safelight and from a "100" reflected from the ceiling. I used two brands of paper—Kodak rapid and Illingworth Normal de Luxe, the former being considerably faster than the latter.

Half of a strip of each was exposed on the bench for five minutes and then developed in darkness for three minutes. The fast paper was perfectly clear, while the slow grade was appreciably fogged in the exposed portion. The solution would appear to be that the slow paper was more colour sensitive.

As I must confess to not having taken the trouble to repeat the observations, I do not put too much faith in them, but Messrs. Ilford's remark seems to confirm the possibility of this solution.

Yours truly,

J. AINGER HALL.

Imperial College of Science and Technology, South Kensington, London, S.W.7. November 13.

HECTOR MACLEAN.

To the Editors.

Gentlemen,—The Croydon Camera Club is very desirous to obtain a really good portrait of the late Hector Maclean, to hang in its meeting-room, as a permanent memento of one who took a leading part in its activities for many years.

We should be very grateful to anyone who would be good enough to supply us with a cabinet portrait for the purpose, or with one that we could have a copy made from.—Yours faithfully,

J. M. SELLORS,
Hon. Secretary.

50, Russell Hill, Purley, November 14.

SILHOUETTES BY REFLECTED FLASHLIGHT.

To the Editors.

Gentlemen,—It is often found when taking portraits against a white sheet, illuminated from behind to obtain silhouette effects, that considerable creeping of light occurs around the edges of the figure. This spoils the clean-cut effect of the outline, and necessitates reducing the negative, so that a passable result may be obtained. Also uneven patches often occur upon the sheet, due, probably, to the light penetrating the sheet unequally. With the intention of overcoming these difficulties I have recently made several experiments, and a process which has proved extremely successful, and has given excellent results, has been devised. An opaque white background is hung against the wall of the studio. In front of this, at about four feet distance, is the sitter, who faces right or left to obtain the profile effect. At a distance of two feet from the background and on either side of the sitter is placed an opaque screen, its position being so arranged that the edge nearest the sitter is just outside the field of view of the lens. The flash, which should be about 30 grains of powder for head and shoulders, is made from behind the opaque screen towards the background and at a position which approximates to the level of the sitter's head. The screen is thus illuminated strongly by the flash and will be found to be evenly lighted. It is necessary that all reflecting surfaces which are likely to throw light upon the sitter's face should be covered, or, in the case of white reflectors, removed from the studio.

Yours faithfully,
"REFLECTOR."

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

F. P.—We should say that you will get at least as quick printing by using a 70 to 100 c.p. Osram or similar lamp at the same distance from the negatives.

M. R. P.—The lens is of far too short a focus. The focal length we prefer is 6 inches for a ¼-plate camera, and often we use one of 8 inches. The general rule is to use a lens of not shorter focus than the diagonal of the plate, but this may be exceeded with a corresponding gain in the rendering of portraits.

S. H.—Two restorers of Daguerreotypes on our books are:—W. B. Samuel, 30, Hampton Street, Walworth, London, S.E.17, and Charles Debenham, 222, West End Lane, Hampstead, London, N.W.6. We have frequently referred people to both of these and we believe they do the work satisfactorily.

K. V.—We should recommend the use of a weaker developer. It is often found that a developer diluted with an equal volume of water will do more in rendering shadow detail than the usual strong solution. In cases of over-exposure, as in white dresses, the water bath is a handy method, allowing the shadow detail to develop while checking the high light.

THISLE.—We expect it means that a molar solution is a molecular weight in grammes of the substance dissolved in 1,000 c.c.s. of water. Silver nitrate, having a molecular weight of 170, a molar solution would be 170 gms. in 1,000 c.c.s. of water, and the solution specified would be one containing 170 × 0.37 gms. in 1,000 c.c.s. water. We do not think the silver solution is one made with ammonia, but simply the ordinary silver nitrate.

WARM BLACK.—The papers which are now available for the obtaining of warm-black tones are slightly slower than ordinary bromide paper, yet it is quite possible to make enlargements upon these slower papers, providing a not too dense negative is used and a fairly strong illuminating source is available. For developers we find the borax M.Q. is as good as any, while the pyrocatechin gives excellent results. A formula for the latter will be found in the "B. J." Almanac for 1922, p. 451.

W. J. A.—As regards general practice in making news photographs, you might be very well guided by a little handbook, "Photography for the Newspapers," by John Everard, out of print just now, but no doubt obtainable second-hand for a shilling or so from Messrs. W. & G. Foyle, Ltd., 121-125, Charing Cross Road, London, W.C.2. You can insert the titles in the way you describe. It is done by commercial makers of these kinds of slide. The title portion may either be written by hand on the celluloid or printed thereon from type. Naturally, the latter method makes a very much neater job.

W. V.—The position is not a very promising one, but if the surrounding walls are kept whitened it will probably be possible to do fairly good work. If this is not sufficient, outside reflectors close to the glass may be used. The amount of glass should be as recommended on page 16 of the "Portrait Studio." Considering the narrowness of the studio, the whole width of the roof should be glass. If possible to have a greater width than 10 ft. it would be desirable to do so. The angle of roof should not be greater than 30 deg. This will mean between 5½ and 6 ft. difference between eaves and top. A flatter roof would be better, but would hold snow too long, besides being difficult to keep free from drip.

G. F. D.—We do not know of a method of "fixing" the dye in stained films for three-colour processes, and we hardly think this should be necessary if the proper dyes are used and the washing reduced to a minimum. If you are working the Sanger-Shepherd process or the Pinatype process, the gelatine image should be so prepared before dyeing that very little washing is necessary, and hot water should not be needed at all after the film is dyed. Possibly the dyes you are using are not satisfactory, the ordinary type of aniline colour proving useless for these processes. This may also account for the colours fading by the action of light. The "Renaud" printing box was made by Marion & Co. and could be obtained for various negatives up to 15 by 12. We should think you could obtain one of these boxes for the size negative you wish to use from the Amalgamated Photographic Manufacturers, Ltd., 3, Soho Square, London, W.1.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3264. Vol. LXIX. FRIDAY, NOVEMBER 24, 1922. Price Fourpence.

Contents.

SUMMARY

In a contributed article Mr. D. Charles describes a system of ascertaining the exposures required when copying originals upon various scales; at the same time a system which is easily within the capacity of a comparatively unskilled copyist. (P. 709.)

Mr. E. A. Dench describes some schemes of window display used by portrait photographers in the United States and elsewhere. (P. 712.)

Results which are defective owing to reflections are encountered not only in photographing glazed paintings, etc., but with other originals in which frequently reflection trouble would not be suspected. An instance is given in a paragraph on page 706.

An exhibition of many notable works by the accomplished portraitist, Mr. N. E. Luboshey, remains open at the Camera Club until the end of the present month. (P. 713.)

In a short studio the difficulty of obtaining a sufficiently great distance between camera and sitter may sometimes be overcome by the use of a mirror. (P. 706.)

In a paragraph on page 705 will be found a caution against undue lowness of temperature of the developing solution in the cold bath process of platinum printing.

The waste incurred by faulty apparatus, a studio fire extinguisher, and the painting of sheet zinc are the subjects of "Assistants' Notes." (P. 713.)

The conclusion of the paper from the Eastman Research Laboratory, in which Dr. S. E. Sheppard reviews the progress which has lately been made in our chemical knowledge of gelatine, will be found on page 710.

In a leading article the writer, Dr. T. Slater Price, usefully supplements Dr. Sheppard's paper by providing an explanation of many of the scientific terms which have come into use in the investigation of gelatine and other colloid substances. (P. 706.)

A formidable process has been patented in Germany for the toning of P.O.P. without gold. Prints are treated in a large number of baths, among which are a sulphide and a selenium solution. (P. 706.)

A process, Neography, is described in a recent issue of "Camera Craft" as possessing qualities of latitude which out-distance those of the Bromoil process and also allow of advantage being taken of photographic detail. (P. 708.)

Details of the construction of an f/2 anastigmat lens are given in a recent patent specification. (P. 714.)

Particulars of the duties levied on various classes of photographic goods imported into the United States are given on page 718.

EX CATHEDRA.

Temperature in Platinum Development.

Although the paper now generally used for black platinum prints is known as the "cold bath" variety, it may be pointed out that the coldness of the developing solution should not be extreme. We have several times found that a very cold solution, say, between 40 degs. and 50 degs. Fahr., has yielded poor, flat granular prints, the defect disappearing when the bath was heated to 65 degs. or over. There is no necessity for warming the acid baths or the washing water, since the absence of a gelatine film precludes the possibility of blisters occurring by the sudden transition of the prints from a warm solution to a cold one. It is perhaps, advisable to give a slightly longer immersion in the acid during cold weather, as nearly all chemical action is delayed by a low temperature. It is not wise to use the acid stronger than the 1-80 solution recommended by the makers; a stronger solution tends to remove the size from the paper, and make it very tender to handle, besides more or less roughening the surface.

Sulphide-Selenium Ton of P.O.P.

Methods of toning P.O.P. prints without gold have been heard of from time to time in the past, yet the use of a sulphide bath, which has been the most commonly recommended process, has never obtained a footing in everyday practice. A variation, or perhaps we ought to say a complication, of this process has, we notice, been evolved by a German firm, the Graphikus Gesellschaft of Hamburg. According to the details, which are given in the German patent specification, the process has reached a forbidding degree of complexity. The P.O.P. requires to be greatly over printed and is first fixed in an 8 per cent. hypo bath containing a half per cent. of potass metabisulphite. Without intermediate washing, the prints are then passed into a similar bath except that the metabisulphite is omitted. They are then well washed and ready for toning. They are first treated in a solution made by soaking up 20 gms. of barium sulphide in a litre of water, pouring off from any deposit and adding 30 c.c.s. to 1,000 c.c.s. of water with addition of 10 c.c.s. of ammonia. In this bath the prints quickly assume the characteristic gold tone. They are passed through a stop bath of permanganate solution (which is renewed several times), again washed and then subjected to the action of a selenium toning bath. This latter is compounded from 35 gms. ammonium hyposulphite, 0.32 gm. of sodium seleno-sulphate and 15 gms. sodium sulphite dissolved in a litre of water with addition of a little ammonia. In this further bath the prints reach a black to brown-black tone, passing on longer immersion to a greenish-black. As soon as the required tone is obtained, the permanganate stop bath is again used and

washing finally done in two or three changes. Although no doubt the production of agreeable tones on P.O.P. prints without the aid of gold has a certain importance, it can hardly be thought that either practical users or experimenters will be encouraged when it is seen what a fearful sequence of operations is required in order to obtain results which, presumably, are satisfactory as regards colour, whatever they may be as regards permanence.

* * *

Mirrors for Short Studios. It is often necessary to work in a very confined space, either when making at-home portraits or where no better accommodation can be found for professional portrait work. We recently were asked to advise upon the possibility of using a room only 11 ft. 6 in. long as an artificial-light studio. This distance is manifestly insufficient for satisfactory full-length work, but by adopting the old device of photographing the image of the sitter, as reflected from a mirror, a considerably greater working distance may be obtained. In a 12-ft. room a mirror 3 ft. high will allow the camera to be placed nearly 5 ft. away from its surface, and still embrace an angle sufficient to cover a full-length figure. It must be remembered that in this case the space occupied by the camera and operator does not have to be allowed for, and therefore the additional distance is all clear gain. It is not found that, working with a narrow angle between lens and sitter, double reflection causes any trouble, while the lateral inversion of the image is readily overcome by using cut films and printing through the celluloid.

* * *

Colour and Density. It is very necessary when printing on bromide paper from mixed batches of negatives to make due allowance for the difference in printing value, due to the use of a developer which gives a yellowish image or even a general yellow stain, and one which gives a pure black negative. It is very desirable, therefore, that negatives should be sorted out into classes by a white light, daylight, by preference, failing which a small arc or a new half-watt lamp will serve. If it be attempted to judge the colour of negatives by an ordinary incandescent lamp, there is great danger of underestimating the density of the yellow ones, with the result that paper is needlessly wasted. We recently encountered some old thin-looking pyro-developed films which were to be enlarged. On making a strip test it was found that (all other conditions being equal) they required four times the exposure, which was sufficient for brilliant non-stained images.

* * *

Surface Reflections in Copying. Every photographer is aware of the necessity for avoiding reflections when copying pictures under glass or those having a perceptibly glossy surface, but there is a more insiduous kind of reflection which often passes unnoticed and causes poor, flat results for which there is no apparent reason. There are many stages between an absolutely matt surface and a decidedly glossy one, and it is very easy to overlook quite a considerable amount of reflective power in both the surface of the paper and the ink or pigment of which the image is composed. In an example which came under our notice this week, the original from which a reduced negative had to be made, was an impression from a line block upon "imitation art" paper. The negative was correctly exposed, but looked flat, the black lines which should have been clear having a slight granular deposit upon them. Upon careful examination of the original this was found to be due to reflection from the surface of the black ink, which was glossy in some places and matt in others. On shifting the position of the camera and copy-board a perfectly satisfactory result was obtained.

THE CHEMISTRY OF GELATINE.

THE paper of Dr. Sheppard is an illustration of the rapid advances which are now being made in the application of strictly scientific methods to photographic problems. In reading this paper the ordinary reader of the "B.J." may very readily become confused, however, since he will find scientific terms of which he does not know the meaning, used in great profusion. To explain all these terms would need more space than can be allotted to this article, so that only the more important can be dealt with.

First, as regards colloidal solutions. The word colloid is derived from the Greek word κολλα, meaning glue. This derivation would indicate that a colloid is a substance of very complex constitution, such as is glue, and at the time when this name was first used by Graham, this was indeed supposed to be the case. This, however, is by no means true, so that the meaning of the term colloid is now quite different from what it was in Graham's time.

It is well known that if a solution of arsenious acid (white arsenic) is acidified with hydrochloric acid and then hydrogen sulphide passed in a yellow precipitate of arsenious sulphide is obtained. If, however, a solution of white arsenic in water is mixed with an equal volume of an aqueous solution of hydrogen sulphide there is no formation of a precipitate, a perfectly transparent, somewhat orange coloured solution being obtained. This solution can be filtered without leaving a residue on the filter paper, and does not settle out on keeping for quite a long time. If, however, a strong beam of light is passed through the solution its path will be shown up very clearly, just as the ray of sun-light is made evident by the dust particles in the air. Pure water, or the solution of an ordinary salt, would not show up the beam of light in this way so long as there were no suspended particles in the water or solution.

This experiment indicates that what is apparently a true solution really contains particles of an insoluble substance suspended in it. Now it is well known that the more finely-ground an insoluble substance is, the longer it takes for it to settle out when shaken up with water, and it is an easy thing to imagine that if it is ground sufficiently finely it would remain in suspension for an indefinitely long period. This is exactly what is assumed to be the case with an orange coloured solution referred to; arsenious sulphide has been formed but in such very fine particles that the solution remains clear to the eye, and no precipitate settles out. The arsenious sulphide is said to be in colloidal solution. Similarly, other substances can be obtained in colloidal solution, and those of silver, gold and the silver halides are especially interesting to the photographer.

In most colloidal solutions the existence of the particles cannot be demonstrated by the highest power microscope, but by the use of the ultra-microscope their presence can in most cases be demonstrated; they are then known as *submicrons*. Those which cannot be rendered visible even by the ultra-microscope are spoken of as *amicrons*. The particles suspended in the colloidal solution are called the *disperse phase:* they are suspended in the *dispersion*

medium (which may be other than water), and their degree of subdivision is known as their *dispersity*.

So far, reference has been made only to colloidal solutions which consist of solid particles in a dispersion medium; such may be called suspension colloids, or *suspensoids*. Suppose now we take an emulsion such as cod liver oil emulsion, or milk; if it is examined under a microscope it will be seen to consist of drops of one liquid suspended in another liquid. If it were possible to reduce the size of the liquid drops to colloidal dimensions we should have, according to Wo. Ostwald, a colloidal solution consisting of liquid particles in a liquid dispersion medium. Substances which give colloidal solutions of this kind, such as gelatine, starch, etc., are called emulsion colloids, or *emulsoids*. This method of consideration has been given for the sake of simplicity, but the constitution of emulsoids is still a matter of controversy, although ideas seem to be tending in the direction of a fibrillar structure (see end of Dr. Sheppard's paper).

Colloidal solutions are generally spoken of as *sols*, so that we may have a suspensoid sol or an emulsoid sol. In the case of gelatine it is well known that when the sol is cooled down it sets to a jelly, whereas no such change takes place with a suspensoid sol, such as that of gold, when treated in the same way. Such jellies are called *gels*, and when water is used as the dispersion medium this is indicated by the terms *hydrosol*, and *hydrogel*. Moreover, the change from sol to gel is reversible, since on warming the jelly it liquefies readily to a sol.

Next, the *gold numbers*, referred to by Dr. Sheppard, call for a few words of explanation. The particles of gold in a gold sol have a size varying from 10–40$\mu\mu$ ($\mu\mu$ = 10^{-6} mm.). If to 10 c.c.s. of a red gold sol 1 c.c. of a 10 per cent. solution of sodium chloride is added, the colour changes from red to blue, and further addition of sodium chloride will precipitate out the gold in flocks. (Such precipitations are characteristic of suspensoid sols.) If, however, a sufficient quantity of gelatine is added to the colloidal gold solution, the addition of 1 c.c. of 10 per cent. sodium chloride will not bring about a change of colour or precipitation, that is, the gelatine prevents the gold from being coagulated; in other words, it acts as a protective colloid.

It is found that different emulsion colloids, e.g., gelatine, casein, gum arabic, etc., have different protecting effects on the gold sol, these protecting effects being represented by what is known as the *gold* number. By this *gold* number is understood the number of milligrams of protective colloid that may be added to 10 c.c. of the gold sol without preventing a change of colour from deep red to violet shades when 1 c.c. of a 10 per cent. solution of sodium chloride is added.

To turn now to the terms *isoelectric point*, p_H, etc. Salts, acids and bases when dissolved in water confer upon the solution the power of conducting electricity; such substances as alcohol, urea, etc., do not have this power. The former are called *electrolytes*, and the latter *non-electrolytes*. According to modern theories, electrolytes have this power because when they are dissolved they split up (*dissociate*) more or less completely into parts which are electrically charged, there being an equal number of positive and negative parts, so that the solution remains electrically neutral. For example, hydrochloric acid gives the parts H^+ and Cl^-, whilst sodium hydroxide gives Na^+ and OH^-. These are generally written, H', Cl', Na', OH', and are called *ions*, the positively charged parts being *cations*, and the negatively charged, *anions*. Substances which produce ions in solutions are called *ionogens*. H'ions, or *hydrions*, confer acid properties on a solution, whereas OH'ions, *hydroxylions*, confer basic properties. If an electric current is passed through such solutions the cations wander towards the cathode and the anions towards the anode. Generally speaking, if a substance possesses acid properties, it does not at the same time exhibit basic properties. It is well known, however, that such a substance as aluminium hydroxide will dissolve in either hydrochloric acid or in sodium hydroxide, that is, it acts as a base towards the former and as an acid towards the latter. Such a substance is said to be *amphoteric*. Gelatine will act as a base towards acids and as an acid towards bases, and is therefore an amphoteric colloid. If, then, it is present in hydrochloric acid solution, the salt GCl will be formed, where G represents the gelatine residue, and this will give the ions G' and Cl'; if this solution is electrolysed the G'ions will migrate towards the cathode. If dissolved in sodium hydroxide, the salt NaG, giving the ions Na' and G', will be formed, and on electrolysis the G'ions, that is the gelatine, will migrate towards the anode. Pure gelatine itself is a stronger acid than a base, that is, in pure solution the few ions formed are mainly H' and G', and therefore the gelatine will wander to the anode on electrolysis. Now by the addition of an external acid to the solution it can be shown that the stretch of the gelatine as an acid will be decreased; and if the proper quantity of this external acid is added there will come a time when the gelatine is equally strong as an acid and as a base. On electrolysis of such a solution there will be no preferential wandering of the gelatine either to the anode or cathode, i.e., the gelatine is said to be *isoelectric*, and the solution is at the *isoelectric point*. When in this condition the gelatine has peculiar properties, showing a minimum swelling power, the solution has a minimum viscosity, etc.

The hydrion concentration (C_H.) of the solution when the gelatine is isoelectric is 2.5×10^{-5}, that is, in 1 litre of the solution there are 2.5×10^{-5} gram hydrion. These hydrion concentrations are usually expressed in another way, due to Sorensen, so that they can be compared more easily. For example, it is not easy at first sight to compare such a series as :—

1×10^{-5}; 4.0×10^{-6}; 1.6×10^{-6}; 6.3×10^{-7}.

This series may, however, be written as :—

10^{-5}; $10^{-5.4}$; $10^{-5.8}$; $10^{-6.2}$

and the order of acidities is at once obvious. In genera practice the 10 is omitted, since it is common to all, and the hydrion concentration expressed by the *minus* logarithms, which are merely the reciprocals of the logarithms of the hydrion concentration, and are generally written —log [H'], or, more simply, p_H (or P_H or p_H). It follows that the greater the hydrion concentration of a solution the less acid it is.

In the case of gelatine the p_H of the isoelectric point is thus 4.7. In pure water, which is neutral, there are hydrions and hydroxylions in equal concentrations of 10^{-7} at 25 degrees, so that the p_H of pure water is 7.

It is hoped that the above will explain a number of the points mentioned in Dr. Sheppard's paper; there are still such terms as "transition point," "Ostwald ripening," etc., but this article is already too long for the space allotted to me by the Editor. A number of points in connection with gelatine are dealt with more in detail in an article published in the August number of the "Photographic Journal," and a summary of the literature on gelatine is given in a report of the Adhesives Research Committee which is being published by the Department of Scientific and Industrial Research, and is now in the Press.

T. S. P.

NEOGRAPHY—A PROCESS OF MAKING TRANSFER PRINTS IN PIGMENTS.

Those who may feel that, among photographic control processes, Bromoil does not allow them enough latitude for the exercise of such technique of draughtsmanship or painting as they may possess, yet nevertheless do not desire to cut themselves adrift from photography, should find their wants met by a process to which the name of "Neography" has been given by its inventor, Mr. James Carl. Our San Franciscan contemporary, "Camera Craft," gives a general description of this process, from which it appears that a drawing or tracing upon a transparent material, containing gelatine in its composition, is worked upon with a stylus and the intaglio lines then linked with a pigment, which apparently should be an oil colour. An impression by contact may then be taken. Our contemporary writes appreciatively of the process after having seen results by it, and suggests methods by which it may be combined with the photographic image.

Neography, though not a photographic process in itself, yet is so closely allied to photography that we are confident it will interest all those photographers who have a liking and an aptitude for drawing. The possibilities of this process in conjunction with the camera are so inviting, we think many will immediately recognise its value. We particularly draw the professional photographer's attention to neography, he will grasp the possibilities of the process in supplying him with that "something new" for the holiday trade.

We have examined several neograms both in monochrome and colour made by Mr. James Carl, the inventor of neography. They were most artistic; these pictures had been on public exhibition in this city, and had won much praise. The process is really simple in itself, but it is the man behind the stylus and the rag that counts.

Neography is a name given to a new printing process by Mr. Carl, and means a new graphic method. This method enters into every field of the printing processes, such as etching, mezzotint, aquatint, and others besides photography. To photographers it supplies manifold mechanical means of printing effects hitherto unknown. It enables the photographer with but an elementary knowledge of drawing to produce etched portraits of landscapes, mezzotint or monotypes so much in vogue in the art world, permitting him, if he chooses, entirely to obliterate the photographic hall-mark of his print and to substitute a purely individual treatment which may be transferred to any paper, leather, silk, or to any other suitable surface.

Neography enables the worker to control his product, that is, to add or eliminate effects according to fancy. He is able to print in any colour, in monochrome or even in multicolour with the use of one plate, and really beautiful effects may be secured thereby. We have no hesitancy in attesting to this as we have seen these multicolour prints. "Camera Craft" is the first publication to be able to give its readers an account of Mr. Carl's beautiful process. He wishes all workers to become familiar with it, both amateur and professional, because of its possibilities.

Neographic prints (or neegrams) are made in the following manner. A combination of celluloid and gelatine is used. The material being transparent can be directly traced upon by placing the design or photograph beneath it and tracing the outline of the original, in this case the photograph, with a needle or stylus. The work is done on the gelatine side, and the lines are scratched and show sunken in the gelatine surface. We may confine ourselves to mere outline, or we may elaborate our work with shading either now or at a later time. The plate when inked is ready for printing, but unlike the old etching process on metal, a photographer's burnisher is used in place of the costly printing press hitherto necessary for reproduction. It will be noticed that there is a certain similarity between this tracing with a needle upon the gelatine-coated celluloid and the scratching or engraving into the copper plate in "dry-point" work. Indeed, if the photographer so wished he could produce an entire portrait in pure lines similar to portrait etchings now existing, but this requires artistic ability. The practical method for the average photographer is as follows:

Let us presume it is to be a portrait. Make a print, place this under the etching material and trace outlines, eyes, hair and such parts of the drapery as the operator wishes to produce. Rub some black or red oil paint, tube colour, into the traced lines, wipe the plate with a cheese cloth so as to clean it, without disturbing the pigment retained in the lines. We now have a picture in opaque lines upon a transparent material. Now, make a negative by contact on a cut film from this transparency.

The next step is to print your portrait from the original negative, but very lightly, showing only slight modelling and faint graduations, then print through the etching negative made from the celluloid tracing upon this original print (double printing): the result should show a very artistic portrait in etched effect. The registration of the two negatives is really not difficult if we adopt a system of guide lines or make a practice of printing with the same two sides of printing frame to register by. On the other hand, the photographer who is an expert copyist may have recourse to copying the first finished print, and thereby duplicate his original without recourse to double printing. It would be probably better if the photographer would confine himself to one, perhaps two, original prints, and push this as a novelty and charge accordingly, rather than to manufacture several copies which would only cheapen the work.

A slower method, but a more artistic one, is to print direct from the celluloid plate on top of the photographic print. There are certain technical points to be observed to make this a success. We must make a reversed print from our portrait to begin with. If the negative is on film, this reversal is simplicity itself by printing from its back. From this print the tracing is made, and when the celluloid plate is etched and inked it is printed from, and that printing reverses the portrait to its original position. The ink to be used in this work is the same as that employed by etchers for printing from their intaglio plates. The transfer of the inked lines to the photographic print is accomplished by passing it in contact with the plate through the burnisher. We might add that where the photographer desires to try this method he should adopt a printing paper of matt surface to secure the best effects.

One of the most valuable aspects of neography is that the photographer or any artist can engrave from his photograph or drawing, then colour the etched plate with various inks, and then transfer the multicloured picture to a sheet of plain paper by passing it through the burnisher or by aid of a letter press. With the latter a rubber blanket must be used.

EXPOSURES IN COPYING

PROVIDED that it is possible to illuminate the copying easel with lamps of sufficient brilliance to enable them to be retained at a fixed distance from all originals, and also to arrange for standard conditions in the dark-room, there is no reason why copying should not be carried out either continuously or very intermittently without errors in exposure. Several writers have dealt with the classification of originals, so that I need not dwell on this point, except to say that my method takes as its basis the copying of an "average" bromide print, and other classes of originals have given to them definite factors for multiplication or division. This, let me say at once, is all the arithmetic that is required in working a quite satisfactory system.

Practically all the confusion and error arise from the fact that the stops as marked upon a lens have very different values when employed in copying work, and the calculations usually proposed to overcome this difficulty are not only cumbersome but usually also are beyond the average junior assistant, more especially when more than one lens is used at varying extensions.

The system which I worked with considerable success for quite a long time was initiated by standardising the power and position of the lamps at the start. Then a lens was put on the camera with a diaphragm aperture of an inch. That is to say, it was probably an eight-inch lens with the iris set at *f*/8, or else an eleven-inch with the stop at *f*/11. The camera was extended so that sixteen inches was the distance from the stop to the ground-glass, and then was slid to and fro (without altering the extension) until some matter upon the easel was sharp. Thus the result obtained was that the actual value of the stop (of one inch actual diameter) was *f*/16. An "average" print was then pinned up and a plate exposed in steps and developed for a given time, and the correct exposure noted.

A sheet of paper was then inscribed with the ordinary apertures from *f*/6 to *f*/45 in a column. Opposite *f*/16 was written the exposure arrived at by the test as just explained. Opposite each other stop was written, in round numbers of course, the proportionate exposures for all the other apertures in the list, by the ordinary rule of halving for each stop larger, and doubling the exposure for each stop lower. As a matter of fact, as the lights were not of great brilliance, a little extra was added to the theoretical exposures for the smaller stops.

This procedure was repeated with a line subject upon a process-plate, and the corresponding exposures marked against each stop. Note that only one test was made in each case, that of an extension of sixteen inches with an actual aperture of an inch in diameter, quite irrespective of how the lens diaphragm was marked.

Having had this double list, for copying upon the plates usually employed, as well as for process-plates, neatly typed, it was mounted on a card which was pinned upon the wall between the dark-room door and the copying camera, so that it could be examined at a glance. A cheap yard-stick was hung beside the camera on the same side so that zero was always above the lens. Obviously the actual extension of the camera could be noted by the figure against which the ground-glass stood. It will now be realised that if the eight-inch lens was in use (with the stop set at *f*/8 as before) the rule would indicate the value of the stop according to the extension in use. That is to say, if the extension registered twenty-two inches, the exposure would be read off on the table against *f*/22, and so on. For other lenses all that was necessary was to set the diaphragm at the figure represented by the focal length of the lens itself to obtain the standard one-inch aperture. For instance, a four-inch lens was used at *f*/4 and a thirteen-inch lens at *f*/13, for which the pointer would be fixed somewhere between *f*/11 and *f*/16.

Similarly for extensions between those representing stop values an exposure between those two upon the list would be given.

If it were necessary to use a smaller actual stop, obviously the exposure would be read off on the list, and this would be doubled for every step down upon the diaphragm, but by employing good lenses of suitable focal lengths this was only required for subjects of exceptionally fine detail and of large area. The only variations that proved necessary were two, and these were not at all under the control of the operator. The first was fluctuation in the strength of the light. After a while it was noted that this occurred usually at specific times of day probably owing to variations of the load at the supply works. If batches of copying were in progress at such times an occasional plate was developed as work progressed to check results. The other trouble was due to the fact that batches of plates of the same make vary in speed. This was overcome by ordering reasonably large supplies, and noting when a new batch came into use and then developing one or two before proceeding. If a decisive alteration in exposures was required a bit of paper would be gummed upon the exposure table with the alteration pencilled upon it, for instance, "+ 25 per cent" meaning, add 25 per cent. to all exposures.

By thus standardising all possible factors, and by reducing practically all the others to a matter of tabulated procedure, it became possible to entrust a junior with large batches of quite difficult copying, including even the production of brilliant line prints from many-coloured originals upon tinted papers and that at the shortest of notice. On the rare occasions that a negative made by this method fell short of the very high standard set, it was seldom so much out that it could not be saved by the ordinary methods of reduction or intensification or by printing upon a suitable paper. Hence it would be quite within the facts to claim for this system a 99 per cent. efficiency. At the same time, it must be pointed out that it is little use adopting one part of the system without the rest. If the distance of the lamps from the easel, or the make of plate or one of the many other factors is frequently altered, any attempt at semi-automatic methods must necessarily fall to the ground.

D. CHARLES.

DALLMEYER CINEMATOGRAPH LENSES.—A new price list just issued by Messrs. J. H. Dallmeyer, Ltd., 11d, Regent Street, London, S.W.1, is a complete catalogue of the various series of lenses designed by the firm for cinematograph cameras and projectors, including condenser lenses for the latter. The series include those of the extreme aperture of *f*/1.9 and also the "Dallon" telephotos. The list is sent free on request.

AUTOTYPE *MEZZOTYPE*.—The Autotype Co., 74, New Oxford Street, London, W.C.1, send us a specimen of a new style of print which they are now offering to professional photographers. The "Mezzotype," as it is called, is a carbon print of cool brown colour, produced upon a very thin transfer paper, which is attached by one edge only to a flexible white mount. The portrait is printed with a soft margin and is provided with a thin cut-out mount bearing an indented line around the aperture. The combination of the rich tones of the carbon print and the added luminosity which the portrait contains through its loose attachment to the supporting mount yields an effect which is highly distinctive, and is one which, we are sure, will recommend itself to photographers who cater for a cultivated class of customer. Mezzotypes are supplied mounted complete at 20s. per dozen in half-plate size; 30s. per dozen in whole plate.

THE MODERN CHEMISTRY OF GELATINE.

[In a recent communication from the Eastman Research Laboratory Dr. S. E. Sheppard reviews some of the most recent work which has been done in the complex problems which concern the part played by the gelatine in the making and use of gelatine dry-plate emulsions. These include the effect of impurities in the gelatine which reduce sensitiveness; viscosity and setting point of gelatine solutions; mechanical strength of jellies and their capacity for swelling; and the behaviour of gelatine in hardening fixing baths and on drying. The paper is being published in the United States in the "Journal of Industrial Engineering Chemistry."]

(*Concluded from page* 697.)

It is not possible here to deal with the data obtained in relation to photographic development. Certain obvious deductions from the data given are, however, of interest. First it will be seen that gelatine films (and emulsions) tend to assume, if not an equilibrium, at least a stationary value, fairly rapidly. In solutions of alkaline carbonates and sulphites, although alkaline, the swelling is less, for concentrations above 5 per cent., than in water, and this depressing effect increases rapidly with the concentration of the salt. This effect is taken advantage of in preparing developing solutions for use at high temperatures, as in the tropics. It may be further noticed that the maximum swelling developed with gelatine on rigid supports tends to be considerably less than that obtained, at the same temperature and p_H with gelatine not attached to a rigid support. In the latter case there is some (though not always a large) dilation in all directions, whereas the photographic layer can only swell normally to the support. If by any means[16] the swelling is forced beyond the limit compatible with this normal swelling, so that the tangential swelling pressure comes into play, two things may happen. The gelatine may frill, and float off the support, or reticulation may occur. This is the production of a network pattern over the film, which spoils the appearance, particularly since the silver particles of the image concentrate in the ridges. Such reticulation is particularly marked after treatment of gelatine with a tanning agent, followed by warm water.

Fixation.

The use of an *acid* fixing bath, primarily to keep down developer stain, involves, as already stated, passage of the gelatine through

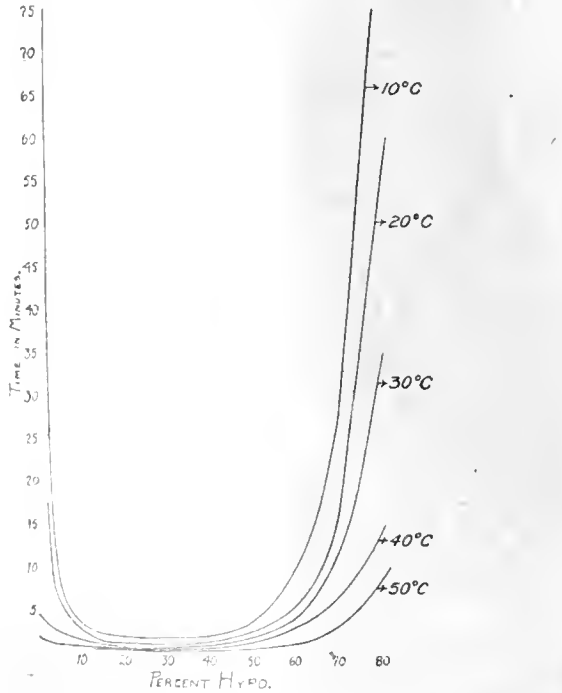

Fig. 11.—Influence of hypo concentration on time of fixation.

the iso electric point of minimum swelling ($p_H = 4.8$). Evidently, if the acidity were considerable, so that p_H approached 3—2, the swelling pressure might increase sufficiently to cause trouble. Actually, however, the p_H of a fixing bath, containing hypo and sulphite, cannot be much less than 4, or otherwise sulphur would be precipitated. The influence of the swelling factor on the rate of fixation (solution of silver bromide in hypo solution) is brought out in fig. 11 and fig. 12. The time of fixation is a minimum for a concentration of thiosulphate of about 40 per

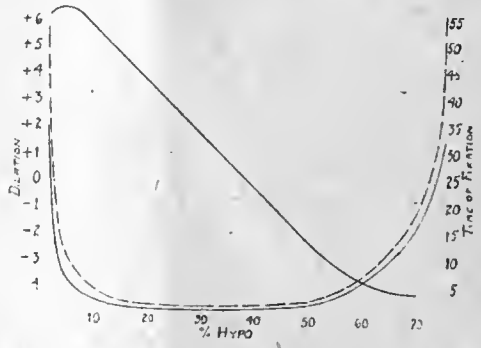

Fig. 12.—Influence of swelling on time of fixation.

cent., above which it again increases. This is due to the fact that from this point on the reduction of swelling more than compensates for "mass action."

The relatively anti-swelling, or temporary hardening effect of the acid fixing bath is generally reinforced by the addition of true hardening (tanning) agents, such as potash alum, chrome alum, or formaline. The hardening action of alums is of great importance photographically, and the writer and his collaborators

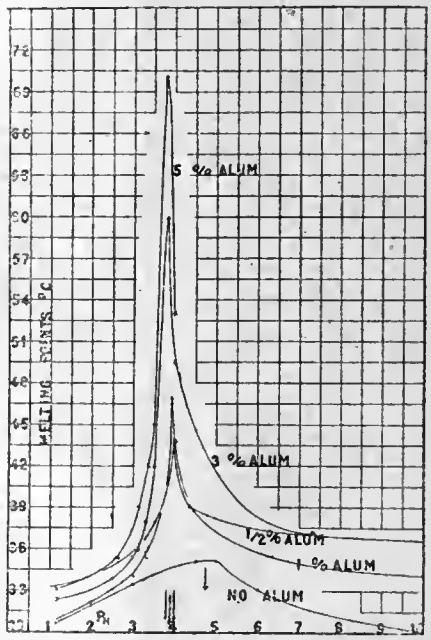

Fig. 13.—Influence of p_H on alum hardening of gelatine.

are making an extended study of the physico-chemical conditions. The influence of the H-ion activity (measured with a hydrogen electrode) on the hardening action of a solution of potash alum [$K_2SO_4.Al_2(SO_4)_3.24H_2O$] is shown in fig. 13.

16. cf. S. E. Sheppard and F. A. Elliott, "The Reticulation of Gelatine." "J. Ind. Eng. Chem.," *10*, 727 (1918).

The "melting points," given as ordinates of the curve, were not determined in the manner given previously, but directly in water, in which the jelly was immersed after it had been soaked a given time in the hardening bath. This corresponds to the conditions in photographic practice. It will be seen that all the solutions give a maximum at the same p_H, about 4.0; this was not changed by altering the p_H of the gelatine, by previous immersion in acid or alkaline solutions. In absence of alum, the maximum occurs at a p_H of 4.7 to 4.8, so that the displacement by the Al seems definite. From J. Loeb's work on the influence of cations, and specifically of $Al^{\cdots}$ [17] on the properties of gelatine, it would seem we should anticipate the maximum hardening at a p_H > 4.7, since for p_H > 4.7 gelatine combines only with cations, for p_H < 4.7, only with anions.

A consideration of the state of aluminium itself in relation to H-ion activity is necessary here, however. This is roughly indicated by the diagram:

Gelatine Combines with Anions.		Gelatine Combines with Cations.
p_H 3		7
	4.7	
Aluminium as $Al^{\cdots}$	$Al(OH)_3$	Aluminium as AlO_2^-

Aluminium commences to precipitate, as hydrous alumina, at $p_H = 3$; precipitation is complete at $p_H = 7$, beyond which alumina

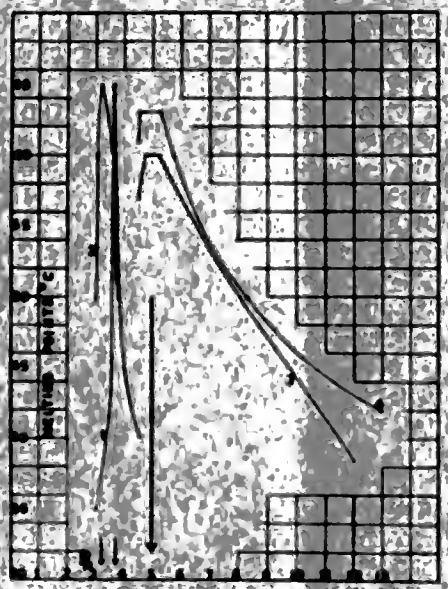

Fig. 14.—(1) 3 per cent. alum, 0.5 per cent. citric acid, 1 per cent. sulphite; (2) as (1) but 2 per cent. sulphite; (3) as (1) but with addition of 25 per cent. hypo.; (4) as (2) but with addition of 25 per cent. hypo.

goes into solution as aluminates. Between $p_H = 3$ and $p_H = 7$ there probably exist complexes, of the type $Al^{\cdots}$ $[Al(O_2)]_x$, which are positively charged, and could combine with a negatively charged gelatine ion.[18] The present results definitely point, however, to combination of Al with gelatine at p_H < 4.7, and it appears possible that this is a mean value, and that some gelatine capable of combination with cations exists for p_H < 4.7. We do, however, find that the addition of sodium sulphite and sodium thiosulphate, as used in making an acid fixing and hardening bath, displaces the p_H of maximum hardening to values > 4.7. This is possibly due to stabilisation of the positively charged Al complexes, and is under investigation. Another interesting point in this connection is this. In an acid fixing bath p_H cannot be much less than 4, otherwise *sulphur* will be precipitated from $Na_2S_2O_3$. Yet, if p_H is > 4, alumina will tend to precipitate and the bath become useless. This impasse is overcome by using, as the acidifier such organic acids as citric, tartaric, etc., which form complexes with aluminium and prevent precipitation by hydroxyl ions. This complex formation lowers the hardening action as shown in fig. 15, since the complex formation

17. "J. Gen. Physiolog." I., 663 (1919).
18. The formation of complex aluminium anions may commence earlier.

removes the $Al^{\cdots}$ ions, and it is necessary to increase the alum content to secure effective hardening. Loeb [19] has suggested that the antagonistic effect of citric acid on the combination of gelatine with aluminium is due to its being tribasic, neutralising a trivalent cation. This is not the case. The antagonistic action

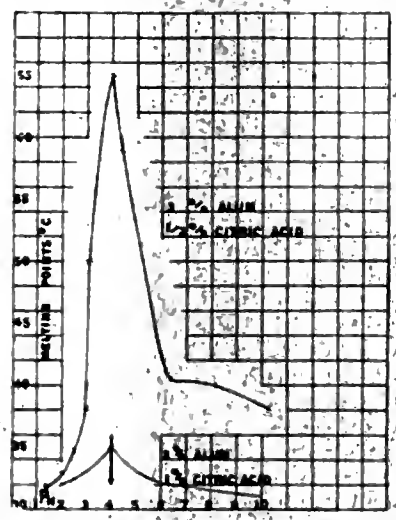

Fig. 15.—Influence of citric acid on hardening of gelatine by alum.

is due to the complex formation, and is shown by other monobasic and dibasic organic acids, but particularly by hydroxy acids. The hardening action of chromium salts is governed by similar conditions, with certain singularities under investigation, and the behaviour of bichromated gelatine is closely connected with these tanning reactions.

It is now in order to note briefly the operations of *washing* and *drying* gelatine plates and films. Washing out substances, such as hypo, etc., from gelatine follows in general the law regulating the washing of precipitates. Two things may, however, be noted. On washing out strong electrolytes from gelatine, it will tend to approach the iso-electric point, but if hydrolyzable substances are present the gelatine will retain unequal amounts of the basic or acidic constituents, the excess depending upon conditions.

It has been impossible, in the space at my disposal, to discuss the many important, if incidental, roles played by gelatine in deviations from or developments of the straight process of negative

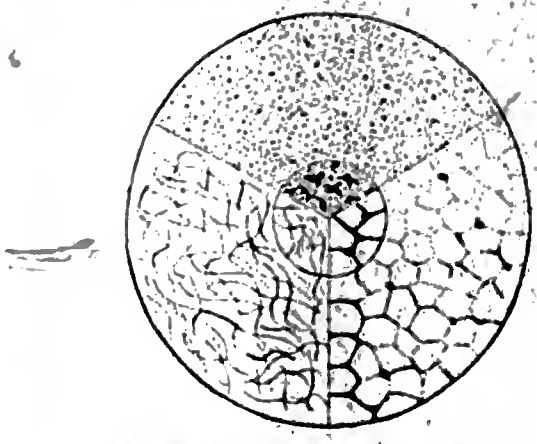

Fig. 16.—Suggested structures of gelatine jellies.

making. Such are: the incidence of hydrolysis and oxidation of the gelatine in photographic operations, its capacity for absorption and fixation of dyes, and many others. Again, the simple operation of drying shows interesting features, one only of which may be mentioned, as bearing upon the so-called "structure" of gelatine jellies. Fig. 16 illustrates three typical structures

19. "J. Gen. Physiolog." I., 504 (1919).

suggested—viz., the "honeycomb" or alveolar, the filamentous, fibrillar or "felt" structure, and the "granular" structure. Appeal is made to these, variously, to explain certain properties of jellies.[20] In particular, the honeycomb or cell structure has been cited in explanation of the effects of the concentration at setting on the swelling of dried jellies. A jelly at 5 per cent. concentration on drying and reswelling again halts at 5 per cent., a 10 per cent., one at 10 per cent., etc. It has been suggested that in the more dilute jellies a more open structure of larger cells is formed. In a recent paper the writer and F. A. Elliott[21] have explained this as a result of external case hardening. Under ordinary drying conditions a non-uniform drying forms a permanently set skin, conserving the original surface extension of the piece of jelly, and this limits the subsequent dilation on swelling. An internal "structure" is therefore an unnecessary hypothesis for the explanation of the concentration effect.

S. E. Sheppard.

20. cf. Physics and Chemistry of Colloids. Report of General Discussion by the Faraday Society and the Physical Society. London. pp. 40-54. (Department of Science and Industrial Research, Great Britain.)

21. "J. Amer. Chem. Soc.," 44, 383 (1922). Dr. T. Slater Price, Director of the British Photographic Research Association, has called the writer's attention to previous notice of the edge drying of gelatine jellies by R. Liesegang. Koll. Zeitschr. 7, 305 (1910); Liesegang, however, does not seem to have related this to the concentration effect.

DISPLAYS THE PHOTOGRAPHIC STUDIO CAN ARRANGE.

More might be done by the studio photographer in making use of his window and showcase display facilities. It is true, of course, that he seldom has the same amount of space at his disposal as the average shop, but his limited scope for display permits of more things being done in this connection than he sometimes realises.

Better than all the theories under the sun are the following examples of how American studio photographers have made attractive and unusual displays in spite of the obvious handicaps they have had to contend with.

Rensler's, Cleveland, Ohio, U.S.A., devoted a display to the babies. The central feature of the window was a large baby doll, dressed entirely in white, who caused the women folk to ejaculate: "Isn't she a darling?" A card placed right behind the baby doll suggested:

"BRING THE BABIES.
Special Care Taken. To-morrow May Be Too Late."

Photographs of babies taken by this studio, and mounted in all sorts of ways, were exhibited on the rear and side walls as well as being spread on the window-floor.

The Balser Studio, Buffalo, N.Y., devoted one of their outside showcases to juvenile photographs, backed up by the following sign:

"CHILDREN'S DAY EVERY MONDAY,
Sittings and one picture absolutely free. Ask us."

The free sitting "bait" may not prove acceptable to some studio photographers, but anyway the Children's Day idea is capable of more widespread adoption. It is hard to handle all appointments for sittings on time when there is a child sandwiched in between sittings for adults, for you never know how children are going to act and how long it will take to get them in the right pose for photographing. The Children's Day prevents grown-ups from being disgruntled in waiting unnecessarily long in the reception room.

Another attractive showcase by the Balser Studio, Buffalo, N.Y., contained only photographs of bridal parties, along with the convincing appeal as below:

"MAKE MEMORIES LAST.
Special Prices to Bridal Parties."

The Allison Studio, 1,210 Market Street, Philadelphia, Pa., worked out quite a novel idea in persuading folk to have their pictures taken. The way in which this was carried out in the outside showcase was by a large picture of Mr. Allison, his face wreathed in smiles, about to photograph somebody in his studio. This picture was appropriately captioned:

"THE PHOTOGRAPHER IS READY TO MAKE YOUR PORTRAIT.
Now is the Time. This is the Place."

Two interesting window displays were recently arranged by Edmonston, Washington, D.C. Appropriately enough, the first display exhibited individual portraits of President and Mrs. Harding and Vice-President Coolidge. There was also an unconventional picture showing Harding and Coolidge together. All these subjects, needless to say, were taken by Edmonston. The portraits were banked against the green cloth background, while on the floor was a display of conservative gilt picture frames, along with a card bearing the following suggestion:—

"Ask to see the frame we have made especially for your photograph."

Grouped at the right of the second Edmonston display was a collection of baby pictures, while grouped at the left were pictures of Civil War days. Modern enlargements of both kinds of subjects formed the convincing exhibit at the middle of the display.

An unusual idea was admirably worked out in a window display by the Bates Studio, Norfolk, Neb. The subject of the window was "The Adventures of a Boy Scout." The pictures forming the various adventures were arranged in logical order in a long picture frame, each adventure being appropriately captioned. The top picture showed the two-year-old son, wearing miniature scout uniform, of a local scoutmaster. Scene two showed the boy parting from his parents at the porch of their home. Other incidents depicted the boy tired after a tramp; building a camp fire; warming himself before the fire; getting homesick; his decision to return home; in the bosom of his home again. Such human interest photographs attracted a great deal of attention while on display, and, no doubt, influenced fond parents to possess permanent records of fleeting boyhood.

Rainy weather need prove no bugbear to the photographer suitably equipped, who does not hesitate to advertise the fact. A rainy week inspired Fred. Hartsook, 285, South First Street, San Jose, Calif., to run an appropriate advertisement beneath the weather forecast in one of the local dailies. The piece of copy was in this vein:—

"Rain and cloudy weather no longer interfere with the making of photographs. Thousands of up-to-date photographers have closed up their skylights, securing superior and more uniform results with artificial light in the posing room. Our studios are all equipped with the latest in operating lights."

The "ad." was set in ordinary reading matter type, of exactly the same kind as that used for the weather forecast, with the word "Advertisement," in order to conform with the postal regulations, printed in small black type. Such an advertisement could be made doubly effective by tying it up with a window or showcase display. A barometer might be placed in the middle of the display of photographs, along with a sign something like this:—

"The Barometer predicts more rain.
But this need not cause you to put off having your portrait made, for our artificially-lighted studio is equal to the best daylight results."

Here is an excellent piece of newspaper copy, run by Oakley's Photographic Studio, Albury, N.S.W., Australia, devoted to baby:—

"THE BABY
you cuddle in your arms to-day will be going to school to-morrow, and the flight of time brings many changes.

A photograph of baby NOW may mean the avoidance of disappointment later.

We LIKE Babies and know how to treat Their Highnesses to get good portraits."

Excellent propaganda, is it not? and is the sort of copy to make mothers stop, pause and ponder.

Ernest A. Dench.

Assistants' Notes.

Notes by and for assistants will be considered for this column. Payment for accepted contributions is made on the first of the month following publication.

The Workman and His Tools.

Although the old saw does not specifically state that a complaint against his tools is evidence of a bad workman, so closely related are the two ideas, by ancient habit, that many a clever worker hesitates to bring upon himself the implied odium, and "carries on" with the apparatus supplied him.

Many a camera has earned its owner many guineas, and, for that reason is cherished as a valuable instrument, though it were better pensioned off. I watched an operator the other day photographing objects of fabulous worth in a world-famed institution. His camera was a square-bellows, for rigidity, of course. But, alas, as he focussed the back wobbled visibly. So it did as he inserted the dark-slide. The latter he furtively carried from the case to the camera under his coat. Most of the slides leaked, he told me, if the greatest care was not taken. He had to stop down more than really necessary, because the looseness of the fittings might throw the picture out of focus.

All that operator's energies seemed to be occupied in overcoming the decrepitude of his apparatus instead of in studying his subject. I feel certain the time he must waste in a year through no fault of his own would pay for a new outfit. (Did I mention that he stuck a pointed match in somewhere to prevent something slipping?)

Last week I was an unwilling guest at a wedding, and for once the inevitable group claimed me as a fellow victim. The result was astonishingly good. Astonishing to me because the poor operator was apparently troubled at every critical moment by something in the apparatus that caused him very evident anxiety.

Seeing that there were *two* of the usual funny men, and a couple of babies and a dog as well, and every minute it threatened to rain, the poor chap's patience was a thing to marvel at. With the best apparatus his would have been no job to envy, but with the obviously rickety old thing he so carefully kept as much as possible under the focussing-cloth it was wonderful that he succeeded so well.

Let your operators have the best you can afford. Second rate gear may work well under favourable conditions, but in the stress of modern business life such conditions seldom occur. The less a photographer has to worry about his handicaps, the more attention he can give to getting his subject to advantage.—Kinton.

Painting Sheet Zinc.—Sheet zinc has many uses in the studio and workroom, and many workers have tried to paint it without success, the surface of zinc, both new and old, not taking kindly to paints and varnishes. The way to treat zinc is as follows:—Take 1 oz. of chloride of copper; 1 oz. of nitrate of copper; 1 oz. of sal ammoniac, and dissolve the three in 3 pints of water; when quite dissolved add 1 oz. of commercial hydrochloric acid. The zinc is brushed over thoroughly with this solution, which turns the zinc a dull black colour, and takes twelve or more hours to dry. When quite dry paint or varnish may be applied in the usual way, the treated surface taking and holding the applied coatings of pigments and varnish very well.—L. T. W.

A Studio Fire Extinguisher.—Accidents will happen, even in the best regulated studios, and fire is one of the most terrifying mishaps. When working in a studio in which a considerable amount of flashlight and magnesium wire was used, extra precautions were called for in the shape of glass bottles of a fire-extinguishing fluid, the latter being made by simply dissolving 2 lbs. of common salt and 1 lb. of sal ammoniac in 5½ pints of water. This mixture was placed in empty pyro bottles, which were afterwards tightly corked and given dabs of red paint. Happily the extinguishers were never called for, but experiments carried out in a back-yard proved the solution to be effective.—L. T. W.

Houghtons' Professional Bulletin for November contains an illustrated interview with Mr. Alexander Corbett, the new president of the P.P.A., photographs of the recent P.P.A. Congress, and notices of some new goods, among them the "Stipwell" mechanical retoucher.

Exhibitions.

PORTRAITURE BY MR. LUBOSHEY AT THE CAMERA CLUB.

When Mr. Solomon J. Solomon, President of the Royal Society of British Artists, opened the annual exhibition of the Royal Photographic Society last September, his eye was caught by a portrait of Sir Henry Trueman Wood, which he declared to be an astonishing piece of work. He said that, although in monochrome, the portrait gave him a vivid suggestion of colour and texture of flesh and hair.

One is glad to see this distinguished portrait again, one of forty or more, at the London Camera Club, in John Street, Adelphi, all of them the work of Mr. N. E. Luboshey, who is exhibiting there during the month of November. The subjects include some eminent people whom everybody knows, and others who are known only to a small circle. There are faces familiar to those who visit the haunts of pictorial photographers in London, and there are others who are known to the country at large through their appearance on the political platform or in the illustrated Press. There are people whom you might meet in the Adelphi or in Fleet Street, and others whom you would have to travel to Stockholm or Copenhagen to see. There are wrinkled old men with bushy beards in this collection, and alert, young-looking men in the full tide of their days. There are men of thought and men of affairs. One feels that Mr. Luboshey has been fortunate in his subjects, ranging as they do from Leo Tolstoy to one at least of the choice spirits of the Croydon Camera Club. All of them are interesting men.

But if Mr. Luboshey has been fortunate in his subjects, his subjects have been even more fortunate in Mr. Luboshey. The men who figure in this portrait gallery are evidently very diverse in temperament and gifts. It is not so much an exhibition of portraits of distinguished men as an exhibition of distinguished portraits. These are portraits of quality, alike in the personal and the photographic sense. You begin the round of the exhibition by trying to analyse the characters presented to you, but before you have done you begin to ask some questions about the man who presents them.

Mr. Luboshey's methods in portraiture are well known, or ought to be. He has expounded them as plainly and painstakingly and picturesquely as possible. If they are not followed widely in photographic portraiture to-day it is not because they are difficult to acquire, but because they are easy. Mr. Luboshey preaches that simple gospel which is above all things difficult to accept. Had he started a school of photographers who lighted their sitters from behind their heads or from underneath their feet, he would have had a crowd of disciples. But when he stands out for straight front lighting from one source—in fact, for the lighting of his sitters as nature herself lights the world—others exclaim that there is no art in doing that. Of all false antitheses, the falsest is that art and nature are opposites. But many think that the acceptance of the ordinary and obvious way of going to work does not give sufficient scope to their own individuality, and so they go in for some eccentric lighting, from behind or from the side, which, combined perhaps with a strained pose and with various methods of control in printing, gives us what might be a picture of trellis work, but is scarcely recognisable as the human countenance.

One turns with relief to such an exhibition as Mr. Luboshey's, for it is unsophisticated, unaffected, simple, direct. The photographer himself is not interposing his own personality. He knows his place; he stands back from his sitters, instead of always putting himself in front of them. He is content that they should speak for themselves. Even in the groups, of which there are one or two examples, there is no great elaborateness of arrangement. Mr. Luboshey has faith in the inherent rightness of the natural scheme of things.

There are some other points to be noted. One is the deft use of collar or cuff or handkerchief (or, in the case of Tolstoy, the light smock) to carry a higher light than the face, and yet to be a foil which makes the face more interesting, for the face is alive and historic, while the other is a bit of inert linen. Another thing is the lighting which he manages to get into his shadows by having his front light at various distances and intensities. The face—and the whole face—is the chief interest, and if anything else comes in at all it is only to assist this main theme. It is rarely that he introduces an accessory. One in-

stance is a microscope, introduced into the portrait of Dr. Rodman, Past President of the Royal Photographic Society, but Mr. Luboshey had to resort to combination printing to get this result, because he found that to include the sitter and the microscope in the one exposure meant that the sitter suffered to some extent from the distraction of a competing interest. The dark ground is almost unbroken in all these portraits. The face appears out of the living blackness or greyness to tell its own unaided story.

These portraits are the work of a man who combines shrewd observation with brotherly sympathy. They are full of character. The people are presented just as they are in real life, with all their whims and foibles, their patience and generosity. There is no smudging or loss of definition, nothing hidden that should have been revealed. One feels that they are men whom it would be good to know—the clubman with his cigar, the editor beaming (or otherwise) through his glasses, the scientist with his implements—but, all the same, one feels that, if it could be managed, it would be a good thing to have Mr. Luboshey there to do the introductions.

H. C.

FORTHCOMING EXHIBITIONS.

December 9 to 31.—Rochdale Amateur Photographic Society. Particulars from the Hon. Secretary, W. Lord, 10, Derwent Street, Rochdale.

1923.

February 5 to March 3.—Northern Photographic Exhibition, City Art Gallery, Manchester. Latest date for entries, January 12. Particulars from the Hon. Exhibition Secretary, Walter Johnson, 30, Hartington Road, Chorlton-cum-Hardy, Manchester.

March 1 to 8.—Birmingham Photographic Society. Latest date for entries, February 15. Particulars from the Hon. Secretary, J. E. Brecze, 178, Broad Street, Birmingham.

March 2 to 31.—Pittsburgh Salon of Photography. Latest date, February 5. Secretary, Charles K. Archer, 1,412, Carnegie Building, Pittsburgh, Pa., U.S.A.

March 13 to 16.—Exeter and West of England Photographic Exhibition. Particulars from the Hon. Secretary, R. W. J. Norton, 4, Buddle Park, St. Thomas, Exeter.

March 15 to 24.—Photographic Fair, Holland Park Hall, Secretary, Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications November 6 to 11.

ENLARGING.—No. 30,424. Photographic enlarging apparatus. W. E. O'Reilly (W. Holden).

FLASHLIGHT.—No. 30,241. Photographic flashlight apparatus. H. Lamplough.

PHOTOGRAPHY.—No. 30,659. Photography. J. S. Lauder.

PRINTING FRAME.—No. 30,428. Photographic printing frame. D. H. O'Neill.

APPARATUS.—No. 30,710. Film treating apparatus. Werkstätte für Feinmechanik Ges.

FILMS.—No. 30,451. Light-sensitive film or layer. Kalle and Co., Akt. Ges.

FILMS.—No. 30,841. Treatment of photographic films. Counsell Film Process and Chemical Co., Ltd.

CINEMATOGRAPHY.—No. 30,449. Cinematograph films. L. G. Egrot

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

F/2 ANASTIGMATS.—No. 187,082 (Aug. 22, 1921).—The invention provides for the correction of all aberrations in a photographic objective; in introducing a correction for positive spherical aberration by an air space having the form of a positive lens; the production of an objective with a negative lens of such formation and in such relation to the other lenses that the telephoto effect is attained; and the production of an objective which will be satisfactory in exceptional cases where the light is uncertain or insufficient. In all the drawings the two forward lenses L^1 and L^2 are of axial thickness d^1 and d^2 respectively, have the radii r^1, r^2, r^3 and r^4 respectively, and are separated by an air space b^1. The third lens L^3 is of axial thickness d^3 and the radii of curvature are r^5 and r^6. The space b^2 separates the lenses L^3 and L^2 and the space b^3 separates the lens L^3 from the lens L^4 which is of axial thickness d^4 and with radii of curvature r^7 and r^8. In figs. 3 and 4 the lens L^4 is replaced by a doublet of lenses. In fig. 3 the doublet lenses $L^{4\,1}$ and $L^{4\,11}$ are of axial thickness $d^{4\,1}$ and $d^{4\,11}$ and with radii of curvature r^7 and r^8, respectively, and with a common radius r^9. In fig. 4 the doublet lenses L^{4a} and L^{4b} are of axial thickness d^{4a} and d^{4b} and with radii of curvature r^7 and r^8 respectively, and with a common radius r^{9a}. The two forward lenses L^1 and L^2 are of strong positive focus and of relatively low dispersive power, being preferably of crown glass. They are placed in the combination with their convex surfaces facing the incident rays. The third or negative lens L^3 of the combination is of double concave form and of relatively high dispersive and high refractive power, being preferably of dense flint glass. The fourth lens L^4, which may be of crown glass, is of positive focus and of relatively low dispersive power. The radius of curvature (r^6) of the posterior surface of lens L^3 is the shortest of any lens surface of the system.

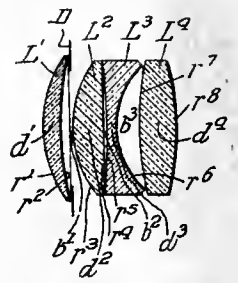

Fig. 1.

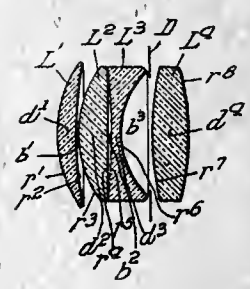

Fig. 2.

The combination of the three lenses L^1, L^2 and L^3 in itself produces the telephoto effect. This condition results in the optical centre of the system being nearer the incident rays than in the ordinary system where it is about in the middle of the system. Since their compnted combined focal length is greater than the amount of racking out ascertained by trial, the actual focus of the lens system is relatively close to the rear lens of the system. The lenses L^2 and L^3 constitute an uncemented doublet, these lenses being formed so that their facing surfaces shall have slightly differing radii. This formation, in conjunction with the other properties of the three lenses L^1, L^2 and L^3, corrects the positive spherical aberration, or may even create a slight amount of negative spherical aberration.

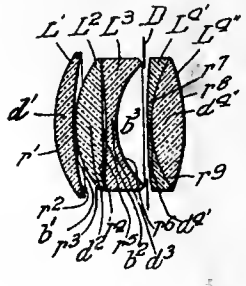

Fig. 3.

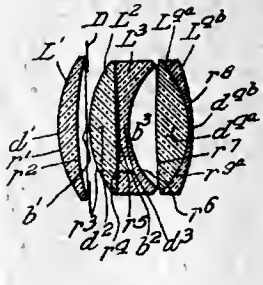

Fig. 4.

Recent photographic experience has shown that high apertures with as much depth of field as is possible is the most desirable condition. Although the three lenses L^1, L^2 and L^3 may be corrected in themselves so as to form a lens system of fair optical performance, the system would be only of a relatively moderate aperture. The addition of the fourth lens L^4, however, produces a lens system corrected to a very much larger aperture. The four lenses shown in figs. 1 and 2 provide sufficient correction for very acceptable

optical performance, but for the further correction of possible outstanding errors, the modified objective shown in figs. 3 and 4 may be used. The lens L^1 is replaced by a cemented doublet of two lenses $L^{1\,1}$ and $L^{1\,11}$ or L^{1a} and L^{1b} of different refractive powers. These latter combinations provide corrective power for neutralising any possible outstanding errors. The diaphragm D may be placed at any suitable point of the system. Herein we have shown it in two different positions, between the lenses L^1 and L^2 in figs. 1 and 4, between the lenses L^2 and L^3 in Fig. 2, and between the lenses L^3 and L^4 in Fig. 3.

One example of the type of objective shown in fig. 1 is given below:—

Radius in Millimetres.			Thickness of lenses and spaces between lenses in Millimetres.	
r^1	+	37.0	d^1 for lens L^1	4.34
r^2	+	76.0	Space b^1	3.00
r^3	+	31.5	d^2 for lens L^2	6.90
r^4	—	——	Space b^2	1.20
r^5	—	160.0	d^3 for lens L^3	3.20
r^6	+	22.5	Space b^3	6.50
r^7	+	80.0	d^4 for lens L^4	7.24
r^8	—	72.0		

The refractive indices n_C, n_D and n_F relating to the C, D and F lines respectively of the solar spectrum and the dispersion y for the different kinds of glass used in this example are:—

			Lens L^1	Lens L^2	Lens L^3	Lens L^4 (below)
n_C	..	..	1.6088	1.51446	1.61205	1.56967
n_D	..	..	1.6120	1.5170	1.6169	1.5726
n_F	..	..	1.61963	1.52305	1.62896	1.57962
y	..	..	56.6	60.2	36.4	57.4

Focal distance 65mm.; diameter of largest lens 38 mm.; effective aperture .5 or $f/2$; anastigmatically flattened field about 65°.

One example of the type of objective shown in Fig. 2 is given below:—

Radius in Millimetres.			Thickness of lenses and spaces between lenses in Millimetres.	
r^1	+	37.0	d^1 for lens L^1	4.34
r^2	+	76.0	Space b^1	.05
r^3	+	31.5	d^2 for lens L^2	6.90
r^4		∞	Space b^2	1.20
r^5	—	160.0	d^3 for lens L^3	3.20
r^6	+	22.5	Space b^3	10.00
r^7	+	80.0	d^4 for lens L^4	7.24
r^8	—	72.0		

The refractive indices n_C, n_D, and n_F relating to the C, D and F lines respectively of the solar spectrum and the dispersion y for the different kinds of glass used in this example are:—

			Lens L^1	Lens L^2	Lens L^3	Lens L^4
n_C	..	..	1.6088	1.51446	1.61205	1.56967
n_D	..	..	1.6120	1.5170	1.6169	1.5726
n_F	..	..	1.61963	1.52305	1.62896	1.57962
y	..	..	56.6	60.2	36.4	57.4

Focal distance 65 mm.; diameter of largest lens 38 mm.; effective aperture .5 or $f/2$; anastigmatically flattened field about 65°.

One example of the type of objective shown in Fig. 3 is given below:—

Radius in Millimetres.			Thickness of lenses and spaces between lenses in Millimetres.	
r^1	+	32.2	d^1 for lens L^1	5.16
r^2	+	79.0	Space b^1	.05
r^3	+	27.6	d^2 for lens L^2	7.26
r^4		∞	Space b^2	0.90
r^5	—	150.0	d^3 for lens L^3	2.70
r^6	+	22.0	Space b^3	8.00
r^7	+	210.0	$d^{4\,1}$ for lens $L^{4\,1}$	1.15
r^8	—	48.0	$d^{4\,11}$ for lens $L^{4\,11}$	8.40
r^9	+	35.0		

The refractive indices n_C, n_D and n_F and the dispersion y for the different kinds of glass used in this example are:—

			Lens L^1	Lens L^2	Lens L^3	Lens $L^{4\,1}$	Lens $L^{4\,11}$
n_C	..	..	1.5372	1.51446	1.61205	1.56967	1.51446
n_D	..	..	1.5399	1.5170	1.6169	1.5726	1.5170
n_F	..	..	1.54629	1.52305	1.62896	1.57962	1.52305
y	..	..	60.2	60.2	36.4	57.4	60.2

Focal distance, 65 mm.; diameter of largest lens 38 mm.; effective aperture .5 or $f/2$; anastigmatically flattened field about 80°

One example of the type of objective shown in fig. 4 is given below:—

Radius in Millimetres.			Thickness of lenses and spaces between lenses in Millimetres.	
r^1	+	32.0	d^1 for lens L^1	5.16
r^2	+	79.0	Space b^1	3.00
r^3	+	27.6	d^2 for lens L^2	7.26
r^4		∞	Space b^2	0.90
r^5	—	150.0	d^3 for lens L^3	2.70
r^6	—	22.0	Space b^3	7.00
r^7	—	210.0	d^{4a} for lens L^{4a}	8.55
r^8	—	48.0	d^{4b} for lens L^{4b}	1.00
r^9	—	22.5		

The refractive indices n_C, n_D and n_F and the dispersion y for the different kinds of glass used in this example are:—

			Lens L^1	Lens L^2	Lens L^3	Lens L^{4a}	Lens 4^b
n_C	..	..	1.5372	1.51446	1.61205	1.56967	1.51446
n_D	..	..	1.5399	1.5170	1.6169	1.5726	1.5170
n_F	..	..	1.54629	1.52305	1.62896	1.57962	1.52305
y	..	..	60.2	60.2	36.4	57.4	60.2

Focal distance, 65mm.; diameter of largest lens, 38 mm.; effective aperture .5 or $f/2$; anastigmatically flattened field about 80°.

The dispersion values given in the foregoing tables have been calculated from the following formula:—

$$n_D - l$$
$$n_F - n_C = y$$

Charles Clayton Minor, 2336 West Monroe Street, Chicago, and Herman Adolph de Vry, 1274 Marianna Street, Chicago.

Film-Changing Device for Roll-Film Cameras.—No. 169,718 (October 1, 1920). The invention describes a photographic camera in which film spools are used and which is provided with an automatic shutter, the operation of the shutter and the changing of the sensitive surface being interdependent or combined so as to avoid any possibility of a double exposure. A single sliding device acts at first on the lever of the automatic shutter and afterwards drives the spool on which the film is wound. For this purpose the sliding device is rigidly connected to a ratchet wheel with which a pawl carried by an arm on a toothed sector co-operates, the sector engaging with a series of teeth on the sliding operating device. A fork for holding the film in place for exposure is included, consisting of a toothed cross-bar adapted to engage in the perforations of the film and coupled to a lever placed under the control of the sliding operating device in such a way that this latter shall release the film before the spool on which it is wound is set in rotation.—Giuseppe Giovanni Battista Tartara, 47, Via Lagrange, Turin, Italy.

Locking Device for Shutter Triggers.—No. 185,538 (June 17, 1921). The invention provides an automatic locking mechanism for the camera shutter which is so arranged that the shutter trigger and mechanism are automatically locked, and thereby the accidental operation of the exposure blades is prevented. When the semi-circular handle of the film spool or reel is rotated and a new film is brought into position, a projection on the handle releases the locking mechanism and the shutter is free to make another exposure.

The object of the invention is to provide cameras embodying means to prevent two or more exposures being made upon one and the same film by positively locking the shutter operating trigger until the winding handle of the film spool is rotated and a new film is in position behind the lens.—John James Holmes-Higgin and Francis Beckwith Holmes-Higgin, Ford Park, Ulverston, Lancaster.

The following complete specifications are open to public inspection before acceptance:

Colour Cinematography. No. 188,329. Colour cinematographic films and method of making same. Technicolor Motion Picture Corporation.

Trade Names and Marks.

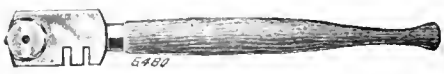
MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register:—

Kodatone.—No. 327,505. All photographic papers. Kodak, Ltd., Kodak House, Kingsway, London, W.C.2, dealers in photographic materials.

New Apparatus.

ENSIGN GLASS CUTTER. Messrs. Houghtons, Ltd., have just placed upon the market a glass cutter consisting of a hardened steel wheel mounted on a metal head, which is provided with two deep notches for breaking off glass of somewhat great thickness.



We have found the little implement most effective for its purpose. It is supplied at the price of 1s. 6d., mounted in a wooden handle, and with six extra cutting wheels. Simply by the use of a small screw-driver a fresh wheel is very quickly placed in position.

New Materials.

Kodatone Collodion Self-Toning Paper. Made by Kodak, Ltd., Kingsway, London, W.C.2.

THIS new collodion self-toning paper has been placed upon the market by the Kodak Co. in two surfaces, matt and glossy, both of single weight and both of the white variety. The papers are printed in precisely the usual way, requiring to be taken to a somewhat greater depth than is desired in the finished prints. The subsequent manipulation consists in first washing the prints in several changes of water, and then fixing in a solution of hypo. 4 ozs. in 30 ozs. of water. This simple treatment yields prints of exceedingly rich and pleasant sepia colour. It should be noted that this result is obtained after thorough washing of the prints. The fact is strongly in the favour of the paper, since it is obvious that the sepia tone is the single result of the materials in the emulsion, and is not in part the outcome of sulphur toning caused by the introduction of acid from the paper into the fixing bath. We have long recommended that choice of a self-toning paper should be made on the strength of its ability to yield good tones even though the prints are well washed before fixing, and we are glad to see that Kodatone comes within this specification. Prints of fine purple brown tone are readily obtained by immersion for five minutes in a weak salt bath, washing in several changes of water, and then fixing in the hypo solution recommended for sepia tones. It is impossible to find fault with the quality of the results most readily obtained on this self-toning paper, which evidently is a material of this kind of the first rank.

Ensign Christmas Mounts and Calendars. Made by Houghtons, Ltd., 88-89, High Holborn, London, W.C.1.

MESSRS. HOUGHTONS' greeting mounts and calendars for the forthcoming season include a series of inexpensive folder slip-in mounts in sizes from vest-pocket to postcard. The mounts are embellished

by attractive cover designs in red and green, and are supplied in sets of six at prices from 1s. 3d. to 1s. 6d. per set. The illustration shows the choice of three designs which is offered.

The calendars are issued in the same series of sizes and in greater variety of style. The series 83 (illustrated) is of the slip-in pattern, of stout dark board covered with a most pleasing white art matt beneath which the print is placed. This style is obtainable in either grey or brown, at prices from 4d. to 7d. each. In

the 83B series, the colours are again either grey or brown and the boards are given a printed border within which the photograph is pasted. The 83A series is also of paste-down pattern and consists of a white flexible hand-made board with deckle edges and plate-mark. A very light and attractive form of greeting calendar. The prices of these two latter series are the same as those of No. 83. In all three series the calendars are supplied only for prints placed "landscape way" on them.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, NOVEMBER 27.

Birmingham Phot. Art Club. "Old Processes and New Methods." W. F. Slater.
Bradford Phot. Soc. Members' Lantern Slide Night.
City of London and Cripplegate P.S. "Amiens Cathedral." E. W. Harvey Piper.
Derby Phot. Soc. "Night Photography." A. H. Blake.
Dewsbury Phot. Soc. "Week-end Cottages in Wensleydale and Wharfedale." G. Thistlethwaite.
Kidderminster and District Phot. Soc. Members' Slides.
Maidstone and District Phot. Soc. "Lantern Slide Making." A. Dordan Pyke.
Southampton Camera Club. "Through the Dolomites to Venice." C. H. E. West.
Willesden Phot. Soc. "Development and Consideration of Negatives." G. C. Weston.

TUESDAY, NOVEMBER 28.

Royal Photographic Society. "Off the Beaten Track at the Zoo." J. E. Saunders.
Birmingham Phot Soc. "The Man behind the Camera and the Making of Portraits." C. P. Crowther.
Bournemouth C.C. Social Evening and Whist Drive.
Cambridge and District Phot. Club. Exhibition of Prints contributed by Scholars of Cambridge Secondary Schools.
Exeter C.C. Exhibition of "Summer Competition" Prints.
Hackney Phot. Soc. Lecture. H. W. Bennett.
Halifax Scientific Society. "Prints and Lantern Slides by the Transferotype Process." W. H. Hammond.
Leeds Phot. Soc. "The Great Masters Interviewed, or a Chat with the Artists of Days Gone By." Rev. W. H. Cooper.
Manchester Amateur Phot. Soc. Whist Drive.
Morley Amateur P.S. "Flower Photography." W. H. Atkinson.

South Suburban and Catford Phot. Socs. "Psychology in the Studio." C. Pollard-Crowther.

THURSDAY, NOVEMBER 30.

Coatbridge Phot. Assoc. Federation Portfolio.
Edge Hill C.C. "Experiences with a 12 in. by 10 in. Camera." W. A. Makinson.
Gateshead and District C.C. "Modern Negative Making." Kodak, Ltd.
Hammersmith Hampshire House P.S. "Quaint Sculptures in England Churches." S. Gardner.
Letchworth Camera Club. "Carbro." C. E. Flemming.
Liverpool A.P. Assoc. "Central Wirral." C. Theodore Green.
North Middlesex P.S. "Working up Enlargement and Prints." Members.
Richmond Camera Club. "Psychic Photography." F. Barlow.
The Camera Club (London). "Biarritz to Carcassonne." Dr. C. Atkin Swan.
Wimbledon and District C.C. "Evils of Faking." R. H. Lawton.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, November 21, Mr. J. Dudley Johnston in the chair.

Mr. Alvin Langdon Coburn made a welcome reappearance, and interested the Pictorial section of the Society with an original discussion upon a subject which is undoubtedly his own. Under the title of "Astrological Portraiture," Mr. Coburn combined the mysteries of the horoscope with every-day work in the studio, and proceeded to classify the classes of sitters, and photographers, who came under the spell of one or other of the twelve signs of the Zodiac. He claimed that by a careful study, which necessitated the knowledge of one's actual date of birth, including the hour and place, of each sitter, and by the making of a horological map it would be possible to get the best pose and expression. Every person, Mr. Coburn solemnly declared, was born under some particular sign, and the characteristics of the section of the Zodiacal circle remained with the individual throughout life. Thus persons born under Aries would possess great energy and force. They would be restless and always endeavouring to improve some particular form of life, while those claimed by Taurus would be quite different. Photographers of this latter state would delight in the photography of gardens and animals, while they would not disdain to portray even the humble bull who was their patron. Gemini claimed persons of wit with brown eyes and restlessness, and photographers were advised to choose their assistants from this class of individual, as they were the best retouchers. The emotional yet homely quality of Cancer's children gave to the portraitist quite an easy going quality. He always had an extremely cosy studio, where cushions and tea were dispensed lavishly, while those of Leo went to the other extreme. The studio of the Leonian was on a large and magnificent scale, gorgeously decorated, and of such imposing grandeur that only a duke would feel at home in it. Virgo was the man for the dark-room. He would carefully catalogue all his negatives, his bottles would be all correctly labelled, and in general appearance his work-room would be spotlessly clean.

To be a successful child photographer it appears necessary to be born under Libra, his qualities reflected in the worker being towards the dispelling of fears. Sitters would be calm and happy immediately they came under the spell of such an operator, and the idea of the dentist's chair would be perfectly dispelled. The lecturer himself belonged to Scorpio, but one failed to notice the facial resemblance which was described by Mr. Coburn. The mystery of photography appealed to this class of people; they did not wish to unravel the chemical and scientific questions, the magic of the whole thing was enough, and they were content. But Sagittarius, of the long type of countenance, was more of a sporty photographer. He favoured the reflex camera, and made his exposures upon horse races and other sports. All press photographers should come under this sign, said the lecturer, if they would be successful. Capricorn was unfortunate. He invariably suffered from rheumatism, and therefore was not keen upon the dark-room work. But he would have a large and well-fitted studio, which would be in a main thoroughfare. His photographs would comprise groups of city companies and luncheons, all of the magnificent and easy kind.

The supporter of all photographic publications was Aquarius, said the lecturer, for he was of the very studious type. He would try all new processes and endeavour to improve old ones. He was keen on invention, and invariably drifted into cinematography. Finally, Pisces claimed the photography of the sea. Marine studies and the smell of tar were associated with this worker, who undoubtedly should be in a section entirely his own.

An interesting discussion followed the lecture, in which many members wished to know their category, but Mr. Coburn said it was not possible to construct a map in so short a time; careful study of the whole subject was first needed. Upon the proposal of Mr. Mellor a hearty vote of thanks was accorded the lecturer for his interesting paper.

CROYDON CAMERA CLUB.

Mr. F. R. Newens, of the Richmond Camera Club, gave a lantern lecture entitled "Rambles with the Paget Colour Plate," pluckily braving a thick and dismal fog and the tortoise velocity of the Brighton line, which of all railways seems the most affected by water-dust particles in the air.

The "office-boy" on drifting in late was welcomed heartily, being accompanied by a bag of loaf-sugar, lemons and a kettle. Mr. Jobling, being aware that rum has a pernicious effect on the liver, with noble self-sacrifice immediately secured the last drop in the only remaining bottle, and received the blessings of all. The betting had reached 10 to 1 against the arrival of the lecturer when he appeared looking as cheerful as a cricket.

Being wishful of reaching home the same evening, by mutual consent all preliminary matter was omitted, and the slides, excellent indeed, only were shown with but brief descriptive comments.

The authority of official instructions bears but lightly on his genial temperament, and he is ever out to experiment in directions deserving of severe official censure. For instance, it is obviously wrong to employ Paget taking and viewing screens in conjunction with Wratten and Ilford panchromatic plates, yet he has obtained very decent results by this fatuous proceeding, accompanied by an appreciable reduction in exposure.

Again, what-properly-brought-up colour-plate worker would dream of using a Sanger-Shepherd graduated yellow filter (x 5 to 0) in front of the orthodox article specially adjusted to the plate? But Mr. Newens often does so. This nefarious practice, he said, secures good skies, clears off a blue veil often present, and vastly improves the rendering of the greens. Other colours, he admitted, frequently suffer a little, but taking a landscape subject as a whole a great improvement may be effected in many cases. It is only fair to record that slide after slide appeared to confirm these statements. A most hearty vote of thanks was accorded him for an evening full of colour.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A meeting of the Council was held at 35, Russell Square, on November 10, 1922. There were present: Messrs. Marcus Adams, Angus Basil, Arthur Bennett, Frank Brown, W. B. Chaplin, Gordon Chase, Alexander Corbett (President), Tom Chidley, C. F. Dickinson, Reginald Haines, George Hana, Herbert Lambert, H. A. St. George, R. N. Speaight (Treasurer), Lang Sims, F. G. Wakefield, H. D. Halksworth Wheeler, together with Mr. Alfred Ellis (Secretary), and Mr. Jenkyn Griffiths. Mr. Alexander Corbett, President, in the chair.

The Secretary stated that, as instructed, he had written the chief constable of Banff, who was the official responsible for the arrangements during the recent royal visit to Elgin, when a complaint was made by a member as to unauthorised press photographers, and the chief constable had replied that no preference was given to any photographers, that no photographers were allowed in the grounds.

Mr. Speaight submitted the balance-sheet of the recent Congress and Exhibition, which he had divided into three separate accounts—an exhibition account (which included the general work of the Congress), an account for the trade section, and an outing's account. He pointed out that certain items which accounted for the adverse balance represented money well spent on behalf of the Association, the benefit of which was already being reaped, and would be further reaped in time to come. The Association had gained 100 new members since January 1, and its status, as a consequence of the Congress and Exhibition, had gone up by leaps and bounds. He wished to place on record his appreciation of the

help given to him by the Secretary in working out the accounts.

On the proposition of Mr. Frank Brown, seconded by Mr. Adams, a vote of thanks was accorded to Mr. Speaight for his work in connection with the accounts.

The following Committees were appointed :—

On the motion of Mr. Chidley, seconded by Mr. Haines, the Finance Committee to consist of Messrs. Chase, St. George, and Wakefield, with the Chairman of Council (and President), Treasurer, and Secretary *ex-officio*.

On the motion of Mr. Brown, seconded by Mr. Basil, the "Record" or Publications Committee to consist of Messrs. Adams, Hana, and Wakefield, with the Chairman of Council, Treasurer and Secretary *ex-officio*.

On the motion of Mr. Chidley, seconded by Mr. Chaplin, the Congress Committee to consist of Messrs. Adams, Basil, Chase, Haines and Wakefield, with the Chairman of Council, Treasurer and Secretary *ex-officio*.

It was also agreed that the convener of each Committee should keep a record of the attendances of the members, and hand such record to the Secretary for inclusion in the Annual Report of Council. It was felt that in the past the bare record of attendance at Council meetings had given an inadequate indication of the labours of the members, many of whom had attended far more Committee meetings than Council meetings, although their attendance at the latter had consumed a large amount of time.

Mr. Basil remarked upon the non-existence of an exhibition committee for other purposes than the Congress exhibition. Hitherto the responsibility of arranging for the representation of the Association at outside exhibitions had fallen upon Mr. Adams. He suggested that a general exhibition committee should be formed, the same to serve as the Congress exhibition committee when the Congress came along.

Mr. Wakefield thereupon proposed, and Mr. St. George seconded, that such an exhibition committee be formed, to consist of Messrs. Adams, Basil, Chase, and Lambert, with the Chairman of Council (and President), Treasurer and Secretary *ex-officio*.

Mr. Adams asked for the necessary authority to put in order the permanent collection of pictures, the property of the Association, and to standardise the sizes of prints to fill, say, four folios, the folios to be purchased at a sum not exceeding £3.

Mr. Adams proposed, and Mr. Brown seconded, that the former should be given this authority, and this was agreed to.

The Secretary read a letter from the Secretary of the Royal Photographic Society stating that a small committee was being appointed to consider a standard size for mounts; that representatives of the Royal Photographic Society and of the London Salon were being selected, and that it was desired to have the co-operation of representatives of the Professional Photographers' Association.

Mr. Speaight proposed, and Mr. Brown seconded, that Mr. Adams and Mr. Basil be appointed representatives on such committee, and this was agreed to. The Council then adjourned after a sitting of four-and-a-quarter hours.

News and Notes.

A Ross-Goerz Lens of 14 inches focus and *f*/7.7 aperture (No. 2,096) has been stolen from Mr. W. M. Crockett, 3, Lyndhurst Road, Devonport. Dealers to whom the lens may be offered are asked to communicate with him.

Mr. T. W. Higginson, for many years in business at Clapton as a trade enlarger and maker of celluloid tinted miniatures, announces his change of address to Cintra, Springfield Road, Sunbury-on-Thames, where the production of these specialties will be continued.

Short-Ray Lenses.—We have to thank the cinematograph trade for yet another new term, namely, "short-ray" pictures. The newspapers of last week stated that an expert audience examined the new short-ray for pictures showing at the Stoll Kingsway Theatre. The old projection gave a throw of 186 ft. from the top of the roof down the big building to the screen. Now several of the boxes in the tier have been sacrificed to the construction of a new projection box. This gives a practically straight throw of 83 ft.

Another "Lightning Photograph."—A remarkable instance of what appears to be a "lightning photograph" in a branch of a beech tree has just been presented to the Royal Botanic Society. The tree was struck by lightning at Mickleham, and there is a clear imprint in a section of the branch of the ivy growing round the tree. In the notices about this curiosity that have appeared in the Press, mention has, of course, been made of images found on the skins of people struck by lightning, but it is rightly pointed out in some papers that neither the image upon the tree nor the images upon the skin are examples of real photography, but markings caused by heat.

Kodak Staff Photographic Society.—Founded early in 1921, this society consisting entirely of members of the staff of Kodak, Ltd., and allied companies, now numbers 400 members. The second annual exhibition was held on Thursday, November 16, in the Lecture Hall, Kingsway Hall, and over 600 prints and many lantern slides were on view. The Society encourages the beginner as well as the advanced worker, and judging by the excellent quality of the work shown much success has been attained. Pictures by members of the staff in many parts of the world, including France, Spain, Italy, Denmark, India, South Africa, Australia, and Singapore were exhibited, while the head office and London branches were well represented. Harrow and the provinces also showed some good work, two prints in this section gaining medals. Mr. W. L. F. Wastell, who judged the exhibits, must have experienced considerable difficulty in making his awards, there being such a wealth of good work. The Society, together with its able and active secretary, Mr. J. M. Hoffmeister, must be congratulated upon getting together such an excellent exhibition.

Houghton's Mounts and Albums.—A most excellent illustrated catalogue of their many styles of mounts and albums has just been issued by Messrs. Houghtons, Ltd., 88-89, High Holborn, London, W.C.1. It is a book of 88 pages, printed in conveniently large type on paper which does ample justice to the many half-tone illustrations of the goods. A classified index shows the pages on which mounts or albums for particular sizes of photographs are catalogued, whilst a numerical index, at the end of the book, forms a key to the pages on which goods known by the makers' trade number are listed and serves also as a price list. The catalogue describes many varieties of slip-in and paste-down albums, of kinds for both the professional and the amateur, and also a very great range of slip-in and other mounts. Several pages are likewise devoted to art mounting boards and papers and passe-partout requisites. The list is issued for the use of photographic dealers, no one of whom can fairly claim to be acquainted with the goods for his customers unless this catalogue is upon his shelf.

U.S. Tariff and Photographic Goods.—By the Tariff Act of 1922, which received the sanction of the United States Senate on September 21 last, duties are levied on goods entering the United States, and, in many instances, are increased. A copy of the Act, which is supplied with a most comprehensive index of the goods affected by it, has been issued in this country by the well-known shipping firm of Thomas Meadows and Co., 35, Milk Street, London, E.C. The photographic goods coming within the Act are cameras and parts, chemicals, dry-plates, films and lenses. The duty on photographic cameras and parts, not specially provided for, is 20 per cent. *ad valorem;* photographic dry-plates, 15 per cent.; photographic and moving picture films, sensitised but not exposed or developed, 4-10ths of 1 per cent. per linear ft. of the standard width; photographic film negatives for use in connection with motion pictures, exposed but not developed, 2 cents per linear ft.; exposed and developed, 3 cents per linear ft.; motion-picture film positives, 1 cent. per linear ft. Films or film negatives, either photographic or cinematograph, exposed in a foreign country by an American producer of motion pictures, operating temporarily in such country in the course of production of a picture 60 per cent. or more of which is made in the United States, are to pay a duty of 1 per cent. per linear ft. Photographic chemicals of coal tar origin, 45 per cent. *ad valorem* based upon the American selling price of any similar competitive article manufactured or produced in the United States, and 7 cents per lb. For two years following the passage of the Act the rate of duty shall be 60 instead of 45 per cent. Photographic and projection lenses, opera and field glasses and other optical instruments, 45 per cent. *ad valorem*. Photographs, 25 per cent. *ad valorem*. Photographs imported by authority or for the use of the United States or the Library of Congress are admitted free, as are also photographs for the use of educational, scientific or literary purposes. Photographs which have been printed more than twenty years are also on the free list.

Correspondence.

BACKGROUNDS IN PORTRAITURE.

To the Editors.

Gentlemen,—*Re* the above subject, would you allow me to say a word as one who abominates the fact of being compelled to attach unsuitable backgrounds to sitters through the difficulty of arranging suitable ones even where they exist? It is not by choice or because of lack of sense of the ridiculous that such pictures are perpetrated, but provision is not made for fixing backgrounds or readily changing them, and operators, especially ladies, may be excused for taking the line of least resistance when their employers have not sufficiently interested themselves in a matter which I consider so vital to the maintaining of continued support from a public which is becoming more critical through the use of the amateur's camera.—Yours faithfully,

DRY PLATE.

THE BRITISH LANDSCAPE EXHIBITION.

To the Editors.

Gentlemen,—With reference to your report on the above exhibition, may I state that the reason I am not exhibiting is not due to any lack of sympathy with the object of the exhibition, but to a lack of new work available at the time of sending in, and to pressure of photographic engagements.—Yours faithfully,

BERTRAM COX.

57, Argyle Road, West Ealing, W.13, November 15.

PORTRAITS OF PHOTOGRAPHIC CELEBRITIES.

To the Editors.

Gentlemen,—The publication in last week's "B.J." of a request for a good portrait of the late Mr. Hector Maclean evidences the need of a file of portraits of men whose names are now, or have been, prominent in the photographic world, and I beg to suggest that the now wideawake Royal Photographic Society is the proper body to undertake and store such a collection of portraits. There is now at the R.P.S. a small collection of portraits of workers famous in the early days of the art of photography, and this collection would form a good nucleus.

As "shoemakers' children are the worst shod," so are photographers the worst (or least) photographed, and I remember that when Mr. Traill Taylor died advertisements were inserted in the "B.J." for a good profile portrait from which the Traill Taylor medal might be made. The scarcity of portraits of photographers is, no doubt, due to the fact that few of them consider it worth while to visit a brother photographer in a professional way, and what portraits do exist are generally to be found in the portfolios of friends who made the portraits.

In the days of the R.P.S. exhibitions at the New Gallery, some scores—possibly hundreds—of portraits were taken with the Platinotype Company's lamp, and, if the negatives still exist, the Company must have an interesting and valuable collection. The R.P.S. would, no doubt, be pleased to have these negatives, or at any rate prints from them. Lamp demonstrations are becoming things of the past, and we must look elsewhere for "stray" portraits, and collections will be found in the possession of well known amateur workers.—Yours faithfully,

H. L. H.

OWNERS OF PHOTOGRAPHS WANTED.—The case referred to under this heading in our last week's issue (page 699) was gone into on Thursday in last week, when Gilbert Martin, 32, canvasser, of Carlton Vale, Kilburn, was at Hendon sent to prison for six months for obtaining medals and photographs from relatives of soldiers killed in the war on the pretence that he would frame them. His practice was to obtain a deposit on account of the work which was never carried out. One hundred photographs were found by the police at Martin's house.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

E. MOSAR.—Almost certainly, it is necessary. There is probably copyright in so recent an etching.

R. B.—The Hermagis lens is made by the Etablissements Hermagis, 29, Rue du Louvre, Paris (2).

W. G.—The only advantage is possibly somewhat finer grain. For contrast you would do better with hydroquinone-caustic.

C. B. M.—For the repair of a focal-plane shutter send to Peeling & Van Neck, Ltd., 4-6, Holborn Circus, London, E.C.1.

W. D. C.—The "flashed" opal glass may be obtained from Messrs. James Hetley & Co., 35, Soho Square, London, W.1.

L. H.—The Central Colouring Co., 516, Harrow Road, London, W.9, would, we think, be the most suitable firm for your purpose.

F. C. TURNER.—(1) No objection; it is regularly done. (2) We can only suggest trying another make of liver of sulphur or of printing paper. Better to use a little ammonia.

J. L.—It is a very old process. Prints are made on ordinary P.O.P. or bromide paper, and after the usual fixing and washing bleached completely in solution of bichloride of mercury. Contact of the prints with paper impregnated with hyposulphite of soda then causes the original image to reappear.

REMBRANDT.—You could possibly obtain instruction in Rembrandt lighting from Mr. John H. Gear, 8, Nottingham Terrace, Marylebone Road, London, N.W.1. A booklet, which would perhaps assist you, is No. 137 of the "Photo-Miniature" series, now out of print, but probably obtainable from Messrs. Houghtons, Ltd., 32-39, High Holborn, London, W.C.1, price 1s. 3d.

A. S. G.—We are sorry we have not by us particulars of the publishers of books of reproductions of the Old Masters. There are several series mostly issued, we think, by Edinburgh publishers. You should pay a call to your local bookseller, who almost certainly will have a stock of the series, or will be able to tell you what they are from the reference books of the general publishing trade. If we were you we should pick out Rembrandt, Gainsborough and Reynolds for a start.

H. W.—We think that two metal filament lamps, each of 2,500 c.p., would be just about of sufficient power in the circumstances you name. You should not diffuse the light too much, that is to say, you should use a fairly thin muslin in front of the lamps. If you care to send a floor plan of the studio showing the present position of the glazing, we could perhaps advise you better. Of course, the length of the place, 12 ft. 6 in., is terribly short, and you will find a lot of difficulty in taking full length portraits.

J. B.—On the presumption that the present copyright law in England prevails also in India, which we expect is the fact, the photographs taken by an assistant in your service and in the course of such service are most emphatically your copyright. We do not think that the assistant is entitled to the negatives or to any rights in the photographs. The answer which we have given applies to England, and has applied there for many years, and we have not the slightest doubt that it holds good in any country where copyright exists.

K. S.—Most of the fixative solutions give matt effects upon drying, but we have found ordinary negative varnish thinned with methylated spirit gives a semi-glossy effect. We should not advise you to apply any of these preparations by means of the Aerograph, owing to the fact that the varnish would clog the small orifices. You could use an atomiser, obtainable from all chemists, which would be far more effective and clean. However, we should think your best method would be to steam the

prints, as this not only fixes the crayon work but gives the semi-glossy effect you need.

A. B.—We should think your best method to illuminate the background would be to use a focussing spotlight. This could be placed upon one side of the studio behind the sitter and the light thrown upon the background and then focussed by means of the sliding lamp tray to cover the area you desire. The background could, therefore, be illuminated from either side of the studio and the area of light altered at will. The background could be given a cloudy effect by the aid of graded filters used in the spotlight. The filters could be easily made from old negatives by scraping, or coating with opaque, as required.

A. L.—(1) $10\frac{3}{4}$ in. is quite a sufficient length for average work. For cabinet heads we do not think it is worth while to purchase a 13-in. or 16-in. lens. (3) We don't think there is any advantage, but rather the reverse, in adding metol to a pyro developer for softness. The pyro-metol is a very energetic combination and gives density very quickly. We think you had far better use your present pyro developer with addition of a certain amount of water, say, one-half the bulk of the working developer for trial. (3) The business of Brucciani has been taken over by the Department for the Sale of Casts, Victoria and Albert Museum, South Kensington, London, S.W.7, to whom you should write.

H. B.—Although your studio is small we think you will require more light than that which you suggest. We think lamps Nos. 1 and 2 should be of 2,000 c.p. each, and No. 3 a standard lamp of 3,000 c.p. Nos. 1 and 2 should be fitted to a runway, and thus would be capable of being placed nearer the background or further away as necessary. Also they should be upon raising and lowering cords and would then be available either high up as toplights or near the floor for children, or alternated, i.e., one up and one down. No. 3, being of the standard type, could be moved to any part of the studio either to assist or counteract the other lamps. Good reflectors should be fitted to all the lamps.

R. P.—If you are requiring sufficient light to enable you to give, say, 1-10th sec. exposures at *f*/4.5, we should advise the "Northlight." This is a 4-carbon arc lamp fitted to a movable stand and with an umbrella-shaped reflector. This lamp, with the aid of a spotlight, would be of great convenience, and enable you to get any desired effect. The half-watt system could be used, but you would require more than 6,000 c.p. to enable such short exposures to be given. Your local electrician should be consulted in reference to fitting the necessary cables and resistance for the "Northlight," and also a wall fitting for the spotlight. It would be best to fit plugs and sockets on both sides of the studio for both these lights.

W. B.—The usual method is to place at least two small bunsen burners in the window and keep these burning during the day and night. These should be fitted by your usual gas-fitter. If your window is entirely enclosed, we should recommend that the top of the enclosure be either taken away altogether or a large-size opening made. This would allow a good circulation of air from the shop or reception-room and would consequently warm the front glass of the window. The following paste should be rubbed over the window after cleaning and then subsequently polished off: Glycerine, 10 oz.; prepared chalk in powder, 4 oz.; mix well together with a pestle and mortar and apply sparingly on a piece of soft rag. Then polish the glass with a dry rag so that no smears occur.

S. K. H.—There are several processes of colour photography which would be of use to you, all of them equally satisfactory. The Autochrome process, particulars from Mr. T. K. Grant, 89, Great Russell Street, London, W.C.1, and the Paget process, particulars from the Paget Prize Plate Co., Watford, Herts., are both transparency processes, and give excellent results, while they are both easy to work. These processes require only one exposure in the camera to produce the result in colour, but are suitable for lantern slides or transparencies for viewing by transmitted light only. For prints upon paper some method of three-colour photography must be worked. Three negatives have to be made, each through a separate colour filter, and from these three prints, which are ultimately superimposed. Having these negatives many processes are possible, including Carbon, Pinatype, etc. Of these latter perhaps carbon is the easiest to work. An interesting process was described in the "B.J." "Colour Photography" Supplement for November 3, 1922. This process, using three negatives, is both simple and effective. A book which may be of use to you is "Practical Colour Photography," by E. J. Wall, published by the American Publishing Co., of Boston, U.S.A., but obtainable from our publishers, Messrs. Henry Greenwood & Co., price 13s. 3d. post free. The colour filters necessary for making the negatives may be obtained from Messrs. Ilford, Ltd., Ilford, London, E.

E. A.—The system of incandescent acetylene light has been so very little used that we ourselves have not had experience of it, and there are very few people, we think, who have. We saw some demonstrations of it some ten years ago at the premises of Messrs. Newton & Wright, 72, Wigmore Street, London, W.1, when it appeared to be just as satisfactory for the projection of lantern slides as the ordinary oxy-hydrogen lime-light. And of course no condenser was used, since the rays from the tiny pastille are brought to a focus by means of a metal mirror. We should say that the intensity of the light is at least six or seven times that of a 120 c.p. half-watt lamp. So far as we remember the light is fairly constant over a period of, say, one or two hours. We have no data as to consumption of acetylene. Possibly Messrs. Newton & Wright could give you further details.

G. M.—We are afraid your studio is hardly large enough for very serious work. You could, however, get bust portraits or even half-length figures with a lens of not longer focus than 6 inches. We should imagine, when working from the extreme end of your studio, that the available distance between camera and sitter would be only about 6 ft., which distance is insufficient for larger work. For children you would require a small table or platform, otherwise you would get distortion due to the awkward angle at which you would have to work. With reference to lighting, we think your present arrangement is quite inadequate. Your windows are too small, but if you could merge the two into one, at both sides of the studio, and carry them down to about 2 ft. from the floor, you would then get better illumination. Also you want a top light, and to obtain this the roof should be glazed to within 4 ft. of the door end. With these alterations, providing you are not shut in by high walls, you would have quite a good amount of light. However, even with this arrangement, it would be necessary to have some other source of illumination near the floor, otherwise the lighting would be too heavy at the top. This could be arranged by having white tilting reflectors on either side of the studio and adjusting them as you find necessary. If electricity is available you could then use the studio as it stands and rely upon the artificial light only. Two lamps of 3,000 c.p. each would be sufficient for bust portraits, but more would be needed for children. We cannot give you any idea of the cost of fitting electricity into your studio, however, as so much depends upon the distance the supply is from you, and local charges, etc. You could best obtain this estimate by applying to an electrician who would be prepared to do the work. Acetylene would be hardly suitable in so small a studio.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3265. Vol. LXIX. FRIDAY, DECEMBER 1, 1922. Price Fourpence.

Contents.

SUMMARY.

In the first portion of a contributed article Mr. Chris J. Symes deals very completely with the working methods which, in his experience, have proved most satisfactory in the Bromoil and Bromoil-transfer processes. (P. 723.)

A simply constructed reflector for the half-watt lamp in portraiture is described and illustrated by a contributor. (P. 725.)

It is officially announced by the Professional Photographers' Association that preparations are being made to hold an "abbreviated" congress at the Photographic Fair to be held at Holland Park Hall from March 15 to 24 next. (P. 729.)

A healthy sign of the demand for photographic goods is supplied by the report of Messrs. Ilford, Limited, for the year ended October 31 last, which discloses a net profit more than £10,000 in excess of those of the preceding twelve months. (P. 721.) A tabular review of the profits earned during the past twelve years will be found on page 730.

We regret to record the death of Mr. Vaness C. Baird, who for nearly forty years was an office-bearer in the Dundee and East of Scotland Photographic Association. (P. 726.)

Automatic focussing vertical enlargers and a pyro-iodide developer are among the subjects of recent patent specifications. (P. 726.)

A good deal can be done to systematise the practice of making prints on bromide paper by the use of a graduated test plate in conjunction with a series of exposures of different times. (P. 722.)

The recent serious explosion in the East End of London, caused by mixing sulphur and chlorate of potash, provides a warning of the strongest kind against the home preparation of flash powder, which necessarily is akin in composition. (P. 721.)

An aid to correct placing of a portrait within the space which it will occupy in the final print is described in a paragraph on page 722.

In tank development of portrait negatives it is preferable, we think, to renew the entire solution fairly frequently rather than to strengthen it from time to time with more concentrated developer (P. 722.)

Exceptions to the law of the diminution of light known as "inverse squares" are often neglected by photographers through omission to observe that the law applies only to a point source of light. (P. 722.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

In a contributed article Mr. H. H. Featherstone outlines the practical methods for the making of three-colour prints by the Bromoil transfer process. (P. 45.)

An enthusiastic French worker of the Autochrome process has put forward the suggestion that the blueness, sometimes encountered in Autochrome transparencies, is due to abnormal composition of solar light, which in turn is the result of sun spots. (P. 48.)

M. Edouard Belin, well known as an inventor of telegraphic transmission of photographs, has devised a non-intermittent mechanism for cinematograph cameras and projectors which, it is claimed, will greatly simplify the problem of colour cinematography. (P. 46.)

EX CATHEDRA.

Flashpowder. It may be remembered that in the early part of last month an explosion took place in a drug store in Sidney Street, Whitechapel, London, E., as the result of which one person died and two others sustained serious injuries. At the preliminary inquiry it was ascertained that packets of sulphur and of potassium chlorate were on the premises, and a pestle and mortar were found near to the scene of the explosion. It has now been officially reported through the London County Council that the explosion was caused by friction in the mixing of the above-mentioned chemicals, which, apparently, were being used for the manufacture of fireworks. It may be as well to lay emphasis upon this incident in reference to the home manufacture of flashlight powder. Although we do not suggest that flash powder, as employed for photographic purposes, is a mixture equal in explosive properties to one of chlorate and sulphur, yet it is very desirable that photographers should recognise that every flashlight mixture is at any rate akin in composition. It would not be a flashlight mixture if it were not. While such mixtures may be kept and ignited without any substantial danger, it is a very different thing when it comes to preparing them oneself. The risk of explosion when grinding together the components of a flashlight mixture is so great as to amount to a practical certainty. The constituents require to be separately ground to the finest possible powder, and even when that is done, the greatest care taken to avoid friction or pressure in compounding the mixture. The whole process is one so charged with danger that for many years past we have consistently discouraged the home preparation of any flash powder whatever.

* * *

The Ilford Dividend. As announced in the financial papers, the net profit made by Messrs. Ilford, Limited, for the year ended October 31 last is £52,235, out of which the directors have allocated a dividend of 8 per cent. on the ordinary shares. The result of the year's trading must be exceedingly satisfactory to those in charge of the Company and to the shareholders, whilst the successful financial outcome forms an undeniable testimony to the merits of the Ilford Company's products in the eyes of users, not only in this country, but in the many markets overseas where Ilford plates and papers have been held in esteem for a generation. As will be seen from the table which we print upon another page, the net profit made by the Company in each of the three complete years prior to the outbreak of war was £33,000 in round numbers. For the years ended October 31, 1914 and 1915, the profit fell to £22,900 and £27,300, respectively. From 1916 to 1921 it has fluctuated between £35,100 and £48,000, reaching this latter figure in 1916. The dividend on the ordinary shares, which remained at 6 per cent. from 1916 to 1918 and was raised

to 8 per cent. for the years 1919 to 1921, has now been maintained at the latter figure, which, we believe, has not been exceeded since 1902-03.

* * *

Tank Development. During the past few weeks we have encountered several cases in which tank-users have complained of poor, flat negatives. In each case it has been found that the trouble was due to exhaustion of the developer, either by an excessive number of negatives or more commonly by intermittent use for too long a time. Many who have been accustomed to dish development seem to imagine that the degree of dilution of a developer does not affect its working capacity, and they overlook the fact that even when more or less protected from the atmosphere the deterioration of a diluted developer is much slower than that of a concentrated solution. It should be understood that we are referring to large tanks as used for portrait work, and not to the smaller amateur ones in which fresh solution is used each time. The practice of keeping a tank solution up to its work by adding fresh strong solution is not conducive to uniform work, as it is not possible to eliminate the bromide absorbed from successive batches of plates. It seems better to use a weaker solution and to renew it more frequently, the increased time needed for development not being of so much consideration as the quality of the negatives.

* * *

Filling the Space. A failing which many photographers, professional or amateur, labour under, is that of placing their subjects awkwardly upon the plate. The figure is either too high or too low, or too much to one side or the other, or the figure cuts the margins in an ungraceful manner if a full-sized print is required. If the knife can be used freely upon the print the fault is easily remedied, but if a half-plate print be ordered, the sitter is not likely to be pleased with a quarter-plate one. An obvious method of overcoming the difficulty is to enlarge the satisfactory portion to the desired size, when the result is often better than would have been obtained directly in the camera, but the obviously correct course is to give more attention to the spacing of the figure upon the ground glass. A useful aid to this may be found in a card mask, the exact size of the trimmed print, which is fixed in contact with either surface of the focussing screen which will clearly define the limits of the plate. A hand mirror may be used to erect the image until the necessary experience has been gained, as many people are misled by the inverted image. It is also a good plan to inspect the focussed image from a distance of 12 or 14 inches, whence faulty placing is more easily detected than from a nearer position.

* * *

Inverse Squares. The familiar law of inverse squares, according to which illumination from the source of light falls off inversely as the square of the distance, is one of those formulæ the truth of which is very often distorted by applying it under conditions in which it does not hold good. Strictly, the rule holds good only in reference to a source of light which is a mathematical point, without area or magnitude, and it fails in proportion as a light-source departs from this definition. Thus, while the illumination produced by a very small source of light, such as the oxy-hydrogen lime-light or a "Pointolite" arc lamp, would follow the rule, it cannot be assumed that the law applies in conditions which prevail in many photographic operations; for example, the use of an incandescent gas burner or electric filament lamp for the exposure of paper behind a negative placed at a distance from the light which is not many times the dimension of the light itself. Moreover, the use of screens or reflectors which diffuse a source of light, that is to say, scatter it in all directions, causes a very substantial departure from the law. We are reminded of these matters by an article in the issue of the "Gas Journal" of November 22 last, in which the author, Mr. A. Renfred Myhill, draws particular attention to quite ordinary conditions in the illumination of surfaces in which the law of inverse squares ceases to apply.

SYSTEM IN BROMIDE PRINTING.

ALTHOUGH at first sight bromide printing, or perhaps more correctly, printing upon papers requiring development, may appear to be a very simple process, it affords almost unlimited opportunities for total or partial failure. It is not difficult for anyone of average intelligence to master the details of exposure and development, but it is quite a different matter when it comes to reproducing upon paper anything like the full scale of tones which is found in a good negative. It may be contended that there is no recognised standard of quality in negatives, but for all practical purposes it may be assumed that a negative exhibiting full detail in the high-lights with as much shadow detail as the producer wishes to appear in the shadows while possessing sufficient density to give a satisfactory colour by development alone, will satisfy most photographers. The question now to be considered is the selection of a paper which will give the desired print from the type of negative which any particular worker regards as satisfactory, and it is not easy to select such a paper from the hundreds of varieties now offered.

The effect of such a bewildering variety of papers seems to be that of unsettling the mind of the worker who finds that with one grade he can secure good prints from negatives which he considers as rather poor in quality, while his good negatives give rather harsh results. If another grade had been tried a totally different conclusion might have been arrived at, and so hundreds of photographers wander through the desert of perplexity during the whole of their career without finding satisfaction.

There is, fortunately, a comparatively easy method of ascertaining the capabilities of any sample of bromide or similar paper; it is by using a step wedge. For our purpose a step wedge may take the form of an ordinary half-plate of ordinary rapidity which has been exposed in strips in the same way as when making a strip test with a negative, but without a negative. Each strip may be half an inch wide, and if the series runs the narrow way of the plate, twelve strips can be obtained. The ratio of exposure between the successive strips, may be chosen so as to give a steep or shallow gradation, that is to say, exposures may be given in the ratio of 1, 2, 4, 8, and so on, or of 1, 1½, 2, 3, 4, etc., or even 1, 2, 3, 4, 5, 6, the object being to secure a negative which appears like a Venetian blind with the laths gradually increasing in density from one end to the other. After exposure, the plate should be developed in a safe light, using a non-staining developer, until no further reduction of silver takes place, when it must be thoroughly fixed so that it will not change colour subsequently. We have now an instrument with which we can gain some useful information. We may find, for example, that the normal paper of one maker gives a harder result than the "contrasty" of another, and so forth.

A convenient way of using our "wedge" is to place a

full-sized piece of the paper to be tested behind it in an ordinary printing frame, and to make another series of step exposures at right angles to those on the plate. If these are given in the ratio of 1, 2, 4, and 8, we shall have four graduated strips, in each of which any given degree of density has shifted its position to one lower down the scale with the successive exposures. If we wish to compare two papers for rapidity only, we place strips of each side by side and expose and develop as if they were on the same paper. It is then quite easy to see the necessary variation to be made in exposure when actually printing. It may avoid annoyance, or even loss, if new batches of paper are tested in this way against the previous deliveries. We have found a variation in the speed in the ratio of 1 to 2½ in two gross packets of paper of the same brand, the same grade, and purchased at the same time, the emulsion numbers only being different.

The real value in this system of testing lies in the fact that the capabilities of any paper are displayed in a much clearer way than is possible by making trial prints from an ordinary negative. If we test two papers and find that on one we can discern ten gradations between the faintest tint and full blackness, and with another we can only get four, we have learned that the first paper is suitable for a fully-exposed negative of ample density, while the other requires a mere ghost of an image.

Now that developing materials have reached a lower price level, there is no excuse for using a developer until it is incapable of giving a good print in a reasonable time. Exhausted developer is answerable for much poor work, for not only does the reducing agent become used up, but every print adds its quota of bromide to the solution. It is difficult to give any proportion between area of paper developed and bulk of solution, since dark full-out prints naturally exhaust a developer sooner than light sketches, and therefore, perhaps, the best plan is to note the time taken for the first appearance of the image in a fresh solution, and to keep the strength up to such a point that this time is not greatly exceeded.

Now that printing boxes are so generally used, much poor work is caused by printing thin negatives with a strong light. Not only is it impossible to get uniform exposures when these are a second or less, but the quality of the image so obtained is never equal to that obtained by a softer light. This may be obtained by interposing thin paper or opal glass between the light and the negative. It is often more convenient to use a piece of opal immediately in contact with the back of the negative, than to open the cabinet to put in a screen.

Time of development is a most important factor in printing. With most papers a decent colour cannot be obtained with less than a minute's development, while two minutes is better; therefore, the exposure should be regulated and the paper selected so that full development can be given. There is no more time occupied, as four or five prints can be developed at once for two minutes, while if only short development is given each must be done singly.

BROMOIL AND BROMOIL TRANSFER.

Bromoil and Bromoil transfer are most fascinating processes, and, year after year, the numbers of advanced workers who take up one or the other increases, but many of them give it up on account of the lack of reliable and up to date information, and the numerous difficulties they encounter. It is seldom, indeed, that their special trouble is referred to in text-books, and real experts are few and far between; so there is no one within reach to put them right or even to suggest methods of tracing the fault. Many of the processes advocated from time to time are unnecessarily complicated, so that a simple and reliable way of working will be a boon to those workers who want to have absolute control.

No other process in photography gives the same quality as Bromoil or Bromoil transfer, and with the exception of bromide (with which control is very limited) they have no serious rival for exhibition work. The results are permanent, consisting only of pigment on gelatine or paper.

Most photographers have some idea of the method employed, but for those who may not have heard anything of the processes, it may be explained that a bromide print is bleached in such a manner that the gelatine of the emulsion will attract an oily pigment in such proportion as the light has acted, the pigment forming the image on the gelatine. A transfer is the pigment image of the Bromoil transferred by pressure between rollers to another piece of paper.

To begin, the character of the negative has an important bearing on the print. It should be fully exposed and lightly developed. There should be plenty of detail in the shadows, but no great density anywhere. As an example, where the average exposure indicated by a meter is about a 75th to 100th it is advisable to give about a 25th, and develop with a weak developer, say half the normal strength, for the usual time for full strength which with most plates of average speed will be about 2/4 minutes according to the developer used. The negative should be very slightly thinner than one which is intended for bromide enlarging simply. The bromide print may be made by contact or enlargement, although in the former case the negative should be very much stronger than indicated above, but as the majority of people now use small plates and enlarge them subsequently, perhaps it would be better to assume that an enlargement is generally used for Bromoil.

The first thing to consider is the make of paper. Since the war, manufacturers, as a whole, have had some difficulty in obtaining gelatine for their emulsions of pre-war quality, and very few of present-day papers are really suitable for this process. A number of makers supply special Bromoil papers, and whilst most of these are suitable for Bromoil, in a very few cases, indeed, are these papers also suitable for transfer. Amongst the papers which I have tried and found suitable are:—

Kodak "Royal"	(White and toned).
Kodak Velvet.	
"Vitegas"	(Specially prepared for Bromoil).
Barnet	(Cream crayon natural surface).
Barnet	(Smooth and rough ordinary).
Barnet	(Tiger tongue).
Barnet	(Semi-matt Card).

Of these Kodak "Royal" is suitable for Bromoil and transfer; "Vitegas" and Barnet "Cream Crayon," "Rough Ordinary," and "Tiger Tongue" for Bromoil only, and Kodak "Velvet" and Barnet "Semi-matt Card" and "Smooth Ordinary" for transfer only.

The type of print to aim for is one with a distinct but slight deposit in the highest lights and no absolute black in the deepest shadows—in short, a print that is rather on the flat side. At the same time, development must be full, and carried as far as possible. At a temperature of 65 deg., the prints should be in any ordinary M.Q. developer for 4 minutes, and in cold weather the time should be extended

until one is absolutely sure that development is complete. That is to say, the minimum correct exposure must be accompanied by the maximum development.

Any ordinary developer will serve. I think (and most Bromoil workers with whom I have been in touch agree with me) that the developing agents have only a slight if any bearing on the final result. My usual developer is M.Q. which differs very slightly from the Kodak formula, and I have also used Amidol. There has never been any noticeable difference in the behaviour of the prints during subsequent operations, which could be due to the developer.

The prints should then be fixed in a *plain* hypo solution—3 ozs. of hypo to 20 of water, fixation must be complete, and to ensure this it is advisable to leave the prints for at least 15 minutes in the solution if thin paper, or 20 minutes if thick paper is used. On no account should acid hypo be used, as in nine cases out of ten, the print fixed in this solution will refuse to bleach. The print should then be very thoroughly washed—two to three hours are essential, for, if there is the slightest trace of hypo in the emulsion during the bleaching operation, trouble will ensue.

The reason why a thin negative is so advisable is obvious from the foregoing, because with a negative that is at all fully developed it will be impossible to get a bromide print of the character described above. At this point I would advise prospective "Bromoilers" to leave a blank margin of about half an inch all round the print, so as to safeguard the brush from moisture during inking.

The next operation is bleaching, the most important operation in the process. This may be proceeded with immediately washing is finished, or, preferably, in my opinion, the print may be dried and bleaching and the subsequent operations done afterwards. So far as I can see, there is no reason why a print should work better after being thoroughly dried except that the gelatine hardens a little on account of the drying, but it always seems to ink up easier after drying than if one proceeds directly after washing.

There are innumerable bleaching formulæ; I have tried many of them, and after a considerable number of experiments with several, evolved the following and find that is the best in my hands for all-round use. It consists of two solutions as follows:—

A.	Copper chloride	160 grs.
	Sodium chloride	2 ozs. 292 grs.
	Hydrochloric acid	3 minims
	Water	10 ozs.
B.	Potassium bichromate	55 grs.
	Water	10 ozs.

For use take 1 oz. of A, 1 oz. of B, and 2 ozs. of water.

It is rather important that the purest ingredients obtainable should be used, that the amounts as given should be exact, and that large amounts of solution should not be made up, as the B solution does not keep very well. The copper chloride in solid form is very deliquescent, that is, it absorbs water from the air readily and consequently should be kept in a well-stoppered bottle. Solutions A and B should not be mixed until immediately before they are required. The potassium-bichromate solution is inclined to become stale after three weeks, so, unless one is constantly using these solutions, it is better that this should be made up in small quantities as required. Solution A keeps for any length of time. Any excess of undissolved sodium chloride (common salt) should be allowed to settle on the bottom of the bottle.

It is most important that all dishes and utensils used in this process should be absolutely chemically clean, and for bleaching especially a dish should be set aside for this purpose and no other. Before bleaching the dry bromide print, it should be placed to soak for 5 minutes in water at a temperature of about 65 deg., or until limp. Not only will this help the bleacher to flow evenly over the print, but it will render the surface of the emulsion into such a condition that the ink is more readily removed if desired than if the dry print had the bleacher poured directly over it.

The damp print is now drained of surface moisture and placed in a dish, and the ready-mixed bleacher is poured on in an even sweep. Eight ozs. will bleach four 15 × 12 prints, and it is not advisable to try more. In about half a minute the effects of the bleacher will begin to be visible, and in about 3 to 3½ minutes nothing but a faint brownish image will remain. The print should be left in the bleacher for a quarter of a minute after the last vestige of black has disappeared from the print. The time of bleaching gives an important indication as to whether subsequent operations are likely to be successful. If it takes more than 3½ minutes or at most 4½ at 60-65 deg., either the print has not been thoroughly washed or the bleacher has not been mixed in the proper proportions. If it takes less than 2½ minutes, it shows that the print has been under-developed and a flat and muddy Bromoil is likely to be the result. Prints should then be washed in running water until the yellow stain has gone. This usually takes about 15 minutes. The print should then be fixed in a solution of hypo of the strength of about 2 ozs. of hypo to 20 of water for five minutes. The temperature of both bleaching and fixing solution should never exceed 65 deg. F. In the fixing bath the print changes from a faint brown to a very faint greenish grey.

After fixing the print should be washed in running water; if for Bromoil for at least half an hour, if for transfer 15 minutes is enough.

Then the print is put to soak in plain water at a temperature which varies according to the make. During this operation the gelatine absorbs water in the opposite direction and in proportion to the action of the bleacher, *i.e.*, in the high lights the maximum is absorbed, in the half-tones about half, and in the darks little or none at all, and as the oily ink employed is repelled by water, it is only accepted by the emulsion in the same degree as the gelatine is tanned or hardened by the bleaching solution.

The temperature at which the prints should be soaked varies according to the make of paper; some are ready for inking directly after washing; others require an initial temperature of as much as 90 deg. F., while the average is from 70-80 deg. F.

The temperature should not be maintained throughout the period of soaking; the water should be at the point indicated by experience as the best for the paper when the print is put in and allowed to cool to the level of the temperature of the room, very little water being absorbed by the gelatine at a normal temperature by those papers which require heat.

The time of soaking also varies and must be found by experiment. As a general rule from 15 to 45 minutes is sufficient. If a number of prints are being treated they may, when soaking is complete, be transferred to cold water in which they will maintain their condition for a few hours. As a guide, the temperature and time of soaking usually required by the papers above-mentioned are as follows:—

Kosmos "Vitegas" for Bromoil	60 deg.—ready after washing.
Kodak "Royal"	75 deg.—20 minutes
,, "Velvet" ...	75 deg.—25 ,,
Barnet (thin)	70 deg.—20 ,,
(All grades mentioned above) (card)	75 deg.—30 ,,

Some workers prefer to dry their prints after washing, and in the case of papers with a soft emulsion, such as "Vitegas," it may be an advantage. Personally, I think it better to go straight through, but it should be remembered that each wetting and drying hardens the emulsion a little, so that longer soaking and higher temperature are required to bring the paper to the right condition.

At this stage, if the surface moisture be blotted off, the

image may be seen in slight relief, the amount of which is some guide as to whether the print is ready for inking: with most papers the relief is distinctly perceptible, with others it is pronounced, and some do not show it at all. One soon acquires sufficient knowledge to judge, however, if the soaking has been accurate, though it should be mentioned that usually the absence of relief indicates insufficient soaking and too violent a relief the reverse.

Another pointer is given by the feel of the paper in the water: the high-lights are slippery and soapy, and the shadows rough to the touch when the print is ready.

Neither of the above are really reliable indications, for different batches of the same paper vary in both feel and amount of relief. The only real proof is the manner in which the ink takes during the next operation.

Before describing the process of inking it would be advisable to discuss the materials necessary, which comprise ink, brushes, plate-glass, petrol, cotton wool, palette knife, and a supply of blotting paper.

Inks.—These are made specially for the process by Sinclair's and Griffin's both of London, and Horsell's, of Leeds. Some lithographic inks are suitable, but it is so much trouble to find them out and try them that it is far better to leave them alone and stick to those specially manufactured. These are excellent, of fine grain, and of the right consistency to start. Mediums are also made by the above firms, and each should be used with their makers' inks, or megilp may be used with any. A start may be made with, say, "Encre Machine" (a hard black), Burnt Umber, or a softer black such as "Encre Taille Douce," and such colours as the worker fancies. Colours used by themselves are seldom satisfactory; they require a proportion of black to give them strength.

Brushes.—Without exception, nothing but those made for the process are any good. The best are those made of genuine pole-cat hair, but they are very expensive and nearly impossible to procure. (I was recently quoted 65s. for a No. 28!) Those obtainable from Sinclair's and Griffin's are very reliable and not so very expensive. For a beginner, a large brush (24 or 28) and two small ones are necessary (say Nos. 14 and 10), and these may be added to from time to time.

Plate-glass.—A piece of plate-glass is about the best thing to place the print on for inking. It should be a good bit larger than the largest size worked. Three-ply wood is a fair substitute if covered with wet blotting paper, but nothing is quite so good as glass. Another piece of glass is required for a palette, on which the ink is spread with a

Palette Knife.—This should be a stiff one with a rounded narrow joint—an ordinary table knife will serve.

Petrol.—Is required for cleaning brushes, palette, and sometimes prints.

Cotton Wool.—Is used for swabbing the surface of the print before inking, and comes in very handily on numerous occasions.

Blotting Paper.—May be photographic or ordinary—fluffless is best.

CHRIS. J. SYMES

(To be continued.)

AN INEXPENSIVE REFLECTOR FOR HALF-WATT LAMPS.

THERE are, no doubt, at this season of the year, many studio proprietors who have in mind the installing of a half-watt lighting system. Although the arrangement of the system is comparatively

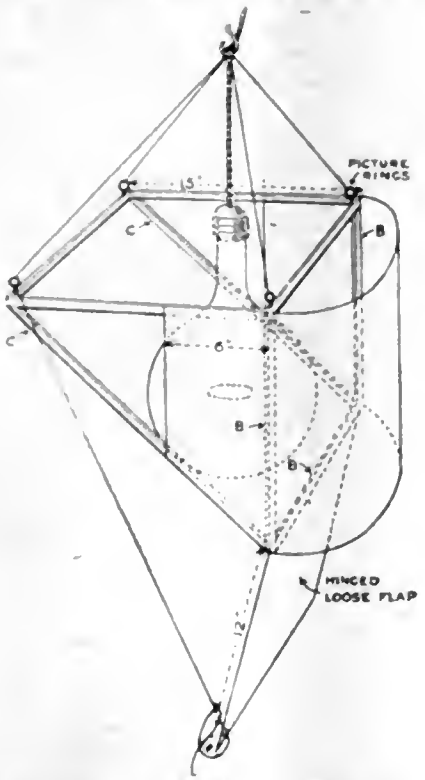

Fig. 1.

simple, there are accessories which, for convenient working, are essential and often expensive; one of these is the reflector.

It has been noted from experience that, generally speaking, there is a great wastage of light in most photographic studios; much of the available light going anywhere but in the direction required. A suitably constructed reflector is, therefore, a great asset. This does not mean that all light should be directed harshly towards the sitter, for it must be realised that a certain amount of stray light reflected from walls and ceiling plays an important part in the general softening of the artificial lighting scheme and is thus valuable in its way. At the same time, it is desirable that the majority of the light should find its way, either directly or by reflection, towards the sitter. Control, by diffusion or other means, is then in the hands of the operator.

With these facts in mind the writer desires to suggest a design for a simply constructed, inexpensive reflector for half-watt lamps.

The reflector suggested is for use in a system of lighting where each lamp is an individual unit. Many arrangements make use of a large reflector common to the light from a number of lamps; but it has been found considerably more convenient to have each lamp and its reflector available individually for disposal according to the peculiar need of the effect in view at any particular time, so that the lamp may be raised or lowered, or otherwise disposed, in its complete form.

The diagram, it is hoped, will clearly illustrate the idea, and also provide a guide for construction.

The materials required are simple and inexpensive. They are:—Wood 12½ feet of ½-inch by ¾-inch stuff; a quantity of cardboard; and a supply of bright tinfoil or leadfoil. These, together with a few screws and picture rings, and a yard or two of cord, are all that is necessary for one reflector.

If expense is no object, the appearance and stability of the article can be enhanced by the use of thin sheet aluminium instead of the cardboard and tinfoil. This metal can be obtained at most large ironmongers about 9d. per square foot.

Now proceed as follows: Cut four lengths of wood 15 inches, and make the square top framework, the ¾ inch way being the depth of the outside. The method of joining, being of little importance, is left to the discretion of the maker. Next cut three more pieces 15 inches long and join two to the top framework, the other making the bottom bar of the back portion, B. B. B. Then join the loose ends of back and top parts by struts 22 inches long,

one at each side, C. C. To complete the wooden structure, trim up the joints, and then affix screw eyes in the top as shown.

A piece of cardboard is now required (outlined in Fig 2), 30 inches long by 15 inches, at its maximum width, tapering (from 6 inches from each end) to the end to a width of 9 inches. If aluminium is used, it must be cut to this size. Having marked a point 6 inches from the back along the top side bars, secure the top corner of the cardboard to these points. Next secure the cardboard to the top back joint of framework, keeping the top edge flush with the top of the bar. The lower edges will now be in position along the structs C. C. and just require fixing. Now arrange the unsecured, wide portion of cardboard in the semi-circular form shown in Fig. 1.

Having cut a piece of cardboard (or aluminium) 15 inches by 12 inches, attach it by a tough piece of cloth, hinge fashion, to the bottom bar of the back framework. A length of thin cord is fastened to the top front corner of the framework—to the picture ring will do—and is passed loosely through a hole in the corner of the loose flap.

The idea of this flap is that, by its means, the rays of light passing downwards may be reflected towards the sitter, the looseness of the flap allowing it to be adjusted to any angle according to the height of the lamp.

Therefore, the cord is left free at one end in order that it may be secured at the length necessary to give the required tilt to the flap. The position of the filament in most half-watt lamps is such that this adjustable reflecting surface is a great asset, making use of those rays which would otherwise pass directly downwards.

If aluminium has been used, the reflector is now complete, but in the event of cardboard being the material, it remains to cover

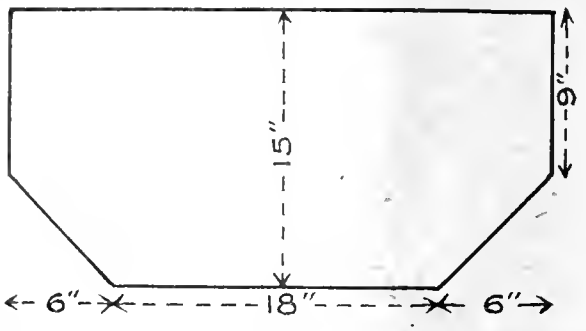

Fig. 2.

the inner or reflecting surfaces with the bright tinfoil, polishing afterwards with a soft duster. The writer used tinfoil in which Kodak films had been packed, straightening it out carefully first, and attaching to the cardboard by a narrow margin of glue near the edges.

Cords or wires are now attached to the four picture rings on the top framework, and then secured to the pendant from which the lamp is swung.

This reflector is quite efficient; adjustments may be required to suit peculiar conditions, modifications in measurements will be required for various sizes of lamps. But the suggestion is a guide to any who may need an inexpensive reflector for half-watt lamps.

F. W.

DEATH OF MR. VANESS C. BAIRD.

We are sorry to record the death of Mr. Vaness C. Baird, connected for nearly forty years with the Dundee and East of Scotland Photographic Association, during thirty-seven of which he served continuously as an officer, three years as treasurer, twenty-five years as secretary, six years as president, and three years as a member of council. Mr. Baird was one of the leading spirits in the establishment of the Scottish Photographic Federation, and at the time of his death was the president of this body. He was a frequent exhibitor at the Scottish Salon, and, as a specialist in architectural photography and in lantern-slide making was accustomed to contribute examples of his technique in these fields of work. Two years ago the award of the Macdougald Plaque for the best print in the Scottish Federation's folio was made to him.

FORTHCOMING EXHIBITIONS.

December 9 to 31.—Rochdale Amateur Photographic Society. Particulars from the Hon. Secretary, W. Lord, 10, Derwent Street, Rochdale.

1923.

February 5 to March 3.—Northern Photographic Exhibition, City Art Gallery, Manchester. Latest date for entries, January 12. Particulars from the Hon. Exhibition Secretary, Walter Johnson, 30, Hartington Road, Chorlton-cum-Hardy, Manchester.

March 1 to 8.—Birmingham Photographic Society. Latest date for entries, February 15. Particulars from the Hon. Secretary, J. E. Breeze, 178, Broad Street, Birmingham.

March 2 to 31.—Pittsburgh Salon of Photography. Latest date, February 5. Secretary, Charles K. Archer, 1,412, Carnegie Building, Pittsburgh, Pa., U.S.A.

March 13 to 16.—Exeter and West of England Photographic Exhibition. Particulars from the Hon. Secretary, R. W. J. Norton, 4, Buddle Park, St. Thomas, Exeter.

March 15 to 24.—Photographic Fair, Holland Park Hall, Secretary, Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications November 13 to 18.

Cameras.—No. 31,242. Photographic cameras. E. T. Percival, and W. C. and W. R. Stevens.

Films.—No. 31,262. Photographic films. S. Cohen.

Photographic Type-setting.—No. 30,932. Photographic type-setting machine. E. K. Hunter.

Plates.—No. 31,025. Preparation of photo-cellographic plates for printing with greasy ink. M. de Sperati.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

Colour Cinematography, No. 157,196 (May 5, 1914). The invention consists in a system of cinematography and colour cinematography in which the film is moved continuously. Rays from the object form an image virtually received, after reflection on an elliptical surface, by a revolving lens. Three coloured filters, corresponding with the primary colours, are arranged in front of the film in order to record the primary colour-sensations or in the projection of the colour films. Thus, three widths of corresponding pictures are in action, instead of one, as in the ordinary methods. Edouard Belin, 272, Avenue de Paris, Le Malmaison, Ruell, France. (Details of the principle of the method and of the apparatus used in its application are given on another page in the "Colour Photography" Supplement.)

Automatic Focussing Vertical Enlargers.—No. 179,948 (May 12, 1921). The invention describes a cam-controlled automatically focussing projection apparatus in which the axis of the lens is substantially vertical and maintained normal to a horizontal projection screen or table. The object of the invention is to provide an apparatus of this type of simple and compact construction which will always prove reliable in action. A vertical support upon which the camera moves, has mounted on or adjacent to it a stationary cam or ramp. An operative connection comprising one or more pivoted levers is provided between the cam and some portion of the camera or lens so that as the camera is moved upon the support relatively to a horizontal table or screen, the relative positions of the lens and the camera back are automatically adjusted to give the correct focus.

In its simplest form a bellows camera is mounted to slide upon a pair of vertical guides between which is fixed a ramp. A lever pivoted to the base of the camera has one end connected to the lens board and its opposite end in engagement with the ramp so

that as the camera is moved upon the guides towards or away from the projection table, the position of the lens relatively to the negative or camera back is automatically adjusted by the ramp to give the correct focus. In the preferred construction, a pair of double-ended levers are pivoted to the base of the camera or to an arm or extension on the camera back. The upper ends of these levers engaging the edges of a cam plate are secured to the vertical support and the lower ends of the levers are connected through links to the lens board. When the camera as a whole is moved up and down the guides, the cam surfaces cause the levers to open or close—after the manner of a pair of scissors—and thus expand or contract the camera bellows so as to vary the relative positions of the lens and the camera back. The weight of the lens and its supporting board, with or without the addition of springs, constantly maintains the upper ends of the levers in contact with the cam plate.

Secured to the back of the camera is a hood or frame adapted to contain an electric incandescent lamp or other source of light, which participates in the movement of the camera. One or more translucent plates are interposed between the source of light and the negative to diffuse the light and, if desired, to secure proper ventilation.

In the construction illustrated the apparatus comprises a cast-iron or similar standard A adapted to be secured by means of a clamp A^1 to the edge of a table B which constitutes the projection screen or table.

Rigidly secured to the upper end of the arm A (fig. 1) is a vertical support C constituting parallel guides for the base D of a camera which can be clamped in place upon the support C by means of a clamping screw D^1. The rear surface of the plate C

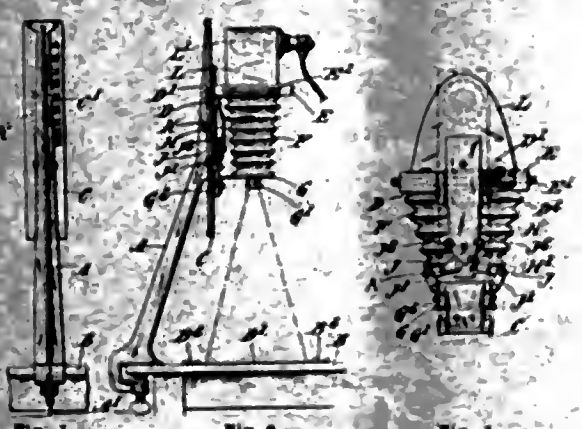

Fig. 1. Fig. 2. Fig. 3.

carries a scale C^1 with which a pointer or indicator D^2 (fig. 3) on the base D can co-operate. Secured to the base plate D of the camera is a back or support E for the negative holder E^1 the camera back being connected by bellows F to a lens board G carrying a lens G^1. The lens board is provided with a supporting foot G^2 which engages the edges of the vertical support C in the same manner as the base D of the camera back. Rigidly secured to the base of the camera D is an arm or extension H and pivoted to this arm at H^1 is a pair of similar double-ended levers J. The lower ends of these levers are connected by links J^1 to the base G^2 of the lens board. At their upper ends the levers J are provided with rollers J^2 which engage the edges of a symmetrical cam plate K secured to the face of the support C. The weight of the lens board and of the parts it carries maintains the rollers J^2 in constant engagement with the edges of the cam J and this cam is so shaped and disposed that as the base of the camera D is moved upon the guides C towards or away from the projection table, the edges of this cam will cause the levers J to open or close, thus expanding or contracting the bellows F and so moving the position of the lens G^1 relatively to the camera back E in such a way as to effect the focussing automatically. By employing a pair of levers in the manner described there is no tendency for the plane of the lens board to twist relatively to that of the negative, thus ensuring accurate focussing. Secured to the frame or back E of the camera is a hood L constituting a reflector for a source of light such as an electric incandescent lamp indicated at L^1. One or more translucent plates are placed between the source of light and the negative to diffuse the light. The apparatus above described can be readily clamped to any existing table which thus constitutes the easel or screen for supporting the paper B^1 upon which an enlarged photographic print can be projected. Any suitable means may be provided for maintaining the paper flat on the table, as for example the flat metal bars B^2 (fig. 2).

The constructional details may be varied without departing from this invention, and it will be understood that in the arrangement shown and described the weight of some portion of the apparatus will maintain the lever or levers in contact with the cam which effects the relative movement between the lens and camera back.—Kodak, Ltd., Kodak House, Kingsway, London, W.C.2 (Assignees of Edwin Coulthard Fritts, Physics Building, University of Illinois, U.S.A.).

Pyro-iodide Developer.—No. 187,932 (April 18, 1921). The invention consists in a pyro-iodide developer for a process which is described in Patent No. 187,638.

A developing solution containing potassium iodide and made from two stock solutions A and B is compounded as follows :—

A.

Pyrogallic acid	10 grs.
Water to	1 oz.

B.

Sodium carbonate	270 grs.
Potassium iodide	50 grs.
Water to	5 ozs.

For use 1 part by volume of A and 5 parts by volume of B are mixed together. In the development of cinematograph films those portions of a picture in which the degree of gradation between light and shades is at a minimum, a developer solution containing a minimum amount of potassium iodide is used. When this portion of the film has been developed, more potassium iodide is added and a portion of the film developed in which the degree of gradation between light and shade is greater than in the first portion developed. More potassium iodide is added as portions of the film having greater degrees of gradation are reached until the entire film is finished. This will result in a completed film in which not only is there evenness of lighting but evenness of gradation between the light and dark portions of the film. In making still pictures the different negatives can be developed in the same manner.

A formula for a developing solution containing potassium iodide and sodium sulphite is as follows :—

Water	8½ ozs.
Pyrogallic acid	11 grs.
Metol	9 grs.
Potassium bromide	4 grs.
Sodium carbonate	200 grs.
Sodium sulphite	40 to 60 grs.
Potassium iodide	20 to 90 grs.

Potassium iodide appears to have the property of reducing the heavy shades of an exposed emulsion without destroying the light shades so that a less contrasting or more soft picture is obtained. If, on the other hand, an amount of sodium sulphite sufficient to reduce heavy shades was used, it would destroy the light shades. It is this property of potassium iodide of reducing the heavy shades without destroying the light shades which makes it possible to obtain a uniform product as well as a desirable surface for contact transfer printing.—E. C. R. Marks, 57 and 58, Lincoln's Inn Fields, London, W.C.2, for Daylight Film Corporation, 229, West 28th Street, New York.

Roll-film Developing and Fixing Tank.—No. 184,753 (Feb. 28, 1922). This tank is a rectangular metal box, fitted with a light-tight cover. An inlet for the developing and fixing solutions is provided in the lid, and an outlet near the bottom of the box. Both of these openings also are light-tight. Beneath the inlet is a metal cross bar, fitted in a position to allow the free insertion of the film spool, but preventing the passage of the flanges of the spool beneath the bar. A strip of wire gauze is fitted to the inner surface of the lid, which presses the film below the surface of the liquid in the tank. For use the lid of the tank is removed, the backing paper of the spool of film to be developed is carefully unrolled until the usual adhesive paper at the end of the film is exposed. The end of the backing paper is then passed under the cross bar and the spool is placed in the tank between the cross bar and the adjacent end of the tank so that the paper will unwind above the film. The end of the film is secured by means of the adhesive paper to the adjacent end of the tank, and the

backing paper is folded back over the spool and the end of the tank. The lid is then placed in position and the projecting paper is drawn out until the junction of the film with the backing paper reaches the slot formed between the lid and end of the tank. The film will now be extended in a single loop lengthwise within the tank, and the various solutions may then be introduced and withdrawn in the usual manner. Amalgamated Photographic Manufacturers, Ltd., 3, Soho Square, W.1, and Max Rycott, 22, Grand Drive, Raynes Park, S.W.19.

New Books.

Pictorial Photography in America. New York: The Pictorial Photographers of America.

This collection of reproductions of work by pictorialists in the United States represents the considered choice of an association which for the past five years has actively interested itself in the advance of pictorial photography, and hence the volume obtains a greater interest as an index to the direction in which those practising photography from aesthetic motives are moving. Accepting this evidence, it seems that our friends in the States are becoming less enamoured of the low key which has characterised much of their work in the recent past. Although there is a fair proportion of work which rejoices in gloom and shadow, yet there is much more than hitherto which is the result of a more cheerful outlook upon Nature. On the other hand, many of those whose work has been chosen are evidently under the thraldom of the cubist doctrine, so that we have things like the "Grey Attic" of Edward Weston, or the "Domestic Symphony" of Margaret Watkins, which are pattern, and nothing but pattern. Fortunately these eccentricities have evidently met with little favour from the committee of selection, which, on the other hand, has given greater prominence to such finely naturalistic work as "Summertime" by Paul Wierum, "Tidewater" by Amelia H. McLean, and "House-Boats" by Ernest M. Pratt. The pages of the 70 odd reproductions are prefaced by one or two short papers, one of which, by Heyworth Campbell, is "On Ideas." Its concluding sentence is as deserving of quotation here as apparently it is in America: "A thought possibly worthy of the deliberation of every artist is that distinction is a result, never the object, of a great mind." As regards the production of the book, everything which fine photo-engraving and extraordinarily good printing can do has been done in order to make the work worthy of the objects which the Pictorial Photographers of America have in publishing it. We are not informed of the price, but last year's issue was published at $3, and, like the present volume, was issued by J. D. Drew, 63, Cliff Street, New York.

The Wellcome Exposure Diary and Calculator.—The 1923 edition of this universally appreciated diary maintains the features which have made it so popular for many years. Notable among these is the exposure calculator for use in conjunction with the numerous tables of the speeds of plates, films, bromide papers and lantern plates. The list of plate speeds now includes all the emulsions in use, including several which for some years past have been omitted. Although confined to instructions for the use of "tabloid" chemicals, the introductory pages of text (which run to more than 70) form a most precise manual for the development, intensification, fixing, etc., of negatives and for the making of prints and lantern slides. Messrs. Burroughs Wellcome have brought their little pocket book to such a state of perfection that the highest praise which can be accorded to it is that it does not fall short in any respect of its immediate predecessors. Three editions are issued, one for the northern hemisphere and tropics, another for the southern hemisphere and tropics, and a third for the United States.

State Purchase of Pictorial Photographs.—The trustees of the Public Library, Museum, and Art Gallery of South Australia have decided to include in their collection of art works a section for photographs. A commencement was made by the purchase of three photographs exhibited at the annual exhibition of the Adelaide Camera Club, held October 4 to 11, 1922.

New Apparatus.

The Sportsman Detective Camera. Sold by W. Watson and Sons, Ltd., 313, High Holborn, London, W.C.1.

Several new models of this very ingenious camera have recently been introduced by Messrs. Watson. The distinctive novelty of the camera is that, in the form of a field glass (monocular or binocular) it provides the means of taking photographs in a direction exactly at right angles to the line in which, apparently, the instrument is pointed, and since the small lens with which the instrument is fitted gives great depth of focus, the camera may be used for obtaining photographs of figures quite close to the user and immediately to his right or left without the subjects being aware that they have been recorded on the plate or film. For these reasons the camera possesses altogether special merits for the

Fig. 1.

Fig. 2.

purposes of the traveller in countries where natives have a religious or superstitious objection to being photographed.

The principle of the apparatus is very simple. The eye-piece, seen in the upper part of fig. 1, is provided with a prism and thus forms a finder, indicating the subject which lies in the field of view to the right or left. The lower part of the body forms the camera proper, which is fitted with an *f*/4.5 lens and a three-speed shutter, adjustable also for time exposures. Focussing is provided by operation of the key seen midway on the drawing of fig. 1. The pointer is set to one or other of the marks 1, 3 and 6 yards, beyond which all is in focus according to the distance of the subject. The speed of the shutter is altered by moving a stud (not shown in the figure) immediately below the finder eye-piece. The shutter speeds are 1-25th, 1-50th and 1-80th of a second. A

Fig. 3.

most ingenious method is employed for stopping down the lens. When the camera is held in one position the lens is working at the full aperture of *f*/4.5, but by turning the camera over a smaller stop, *f*/9, comes into position in the lens. Thus, either *f*/4.5 or *f*/9 can be used at will, for exposures in the hand or with the instrument placed upon a solid support. In the model at present under description, namely, the No. 2, the camera is made to accommodate either a single metal slide or a film-pack adapted for pictures of vest-pocket size, viz., 4½ x 6 cm. It may also be obtained at the same price, £14 10s., in the binocular form, shown in fig. 2, in which a changing box is made in the form of part of the body of a binocular. The changing box holds 12 plates, and is, of course, detachable for loading and unloading. Apart from this feature the only difference between the two models is that the binocular is fitted with an *f*/6.3 lens. There is also a popular model fitted with 6 slides and achromatic doublet lens at the price of £5 5s., and a de luxe model for 4½ x 10.7 cm. plates, fitted with either changing box or 12 single slides at the price of £17 5s. All the above prices include a solid leather case of the form shown in fig. 3.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, November 28, Dr. G. H. Rodman in the chair.

Mr. J. E. Saunders, F.Z.S., delivered a lecture, illustrated by many lantern slides, entitled "Off the Beaten Track at the Zoo." The lecturer and a lady friend had become on such goods terms with animals at the Zoo that they were able to enter the cages and take photographs at close quarters. It was necessary, said Mr. Saunders, to be, first of all, an animal lover, as most of the creatures one wished to photograph knew instinctively who were their friends and who were not. It was also necessary to use apparatus which was simple in operation and as nearly noiseless as possible. The using of an ordinary plate-holder was sufficient to startle the wolf or the vulture, while a plate magazine would turn his fear to rage. Many interesting lantern slides were shown, in one of which the lady friend of the lecturer was shown painting the tooth of the hippopotamus, who weighs three tons, with iodine. This was on account of the animal having toothache.

On the proposition of the Chairman a most hearty vote of thanks was accorded to the lecturer, and also his lady assistant.

CROYDON CAMERA CLUB.

Mr. C. M. Thomas gave a lecture entitled "Photography and the Plate." As it has previously been given at the R.P.S., and fully reported, it is not proposed to do more than glance at a highly interesting and instructive discourse, a resolution accentuated by the difficulty of making notes in the semi-darkness which many slides necessitated.

Of particular interest was a photo-micrograph, over 1,800 diameters, of the grain of a dry-plate, with all sizes and curious shapes of silver particles aggregating. This, and other slides of the as-easy order, formed light relief to much heavy business in the diagram line.

The lecturer remarked that between scientists and pictorial photographers a ravine existed, ever getting wider and deeper, it being bridged only by the S curve beloved by both in very different applications. The first statement is, unfortunately, only too true, and this being so, free-lance investigators of the lecturer's type are of great value to any photographic society, as they span the gulf and enable the everyday photographer to understand a sufficiency of the principles underlying his craft. Also by expressing doubt on authoritative pronouncements, when an honest doubt exists in Mr. Thomas's mind powerful assistance is rendered to a healthy discussion. At Croydon this stopped short of reading the Riot Act.

Compared with Messrs. Purkis and Budd, and others, who simply bristled with points, a porcupine would have made but a poor show, and the lecturer also was fairly bombarded with questions. On the plaintive lament side was Mr. Walker. This popular member, ever struggling under adversity with fifty-guinea cameras, had experienced halation, which blazed into the next street, on backed, and dyed-subatratum dry plates, supported by violent irradiation within the film, and scatter due to reflection from the bellows and other causes. He appealed to Mr. Thomas for aid, who, diagnosing the case, tendered sympathy. Mr. Acroyd, too, had been in trouble with an acute "gamma" due to operating a Continental roll-film whilst abroad. A most hearty vote of thanks was accorded the accomplished visitor from Richmond.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A meeting of the Council was held on November 24, at 35, Russell Square. Present:—Messrs. Marcus Adams, Angus Basil, W. B. Chaplin, Alexander Corbett, C. F. Dickinson, W. E. Gray, Reginald Haines, H. A. St. George, R. M. Speaight, together with the Secretary (Mr. Alfred Ellis), and the Editor (Mr. Jenkyn Griffiths). Mr. Alexander Corbett in the chair.

Respecting the 1923 Congress, the Chairman and Secretary reported that, in company with Mr. Wakefield, they had seen Mr. A. C. Brookes with regard to possible accommodation at Holland Park during the Photographic Fair of March 1923. Mr. Brookes had directed them to some premises within a few minutes' walk of the hall, which consisted only of a meeting room, without provision for social gatherings or refreshments. It was then suggested that a portion of the gallery at the Holland Park Hall, immediately over the entrance, should be partitioned off, making a room measuring about 15 x 40 feet, to be used as a kind of lounge or welcome club for members of the Association. No lectures could be given in so small a space, but it would be possible, with this as an anchorage, to hold a Congress of limited scope, with one or two outings, a luncheon, and the annual general meeting, the idea being to meet the wishes of the many members who desired a spring gathering, although, owing to the fact that only six months would have elapsed since the Association's big congress, it would not be possible to hold a congress of a full-dress character so soon.

Mr. Basil proposed, and Mr. Adams seconded:

That the Association hold an abbreviated congress during the time of the Photographic Exhibition at Holland Park in March 1923, and that Mr. Brookes's offer to erect and furnish a Welcome Club, as arranged with the sub-committee, at Holland Park Hall for the period of his exhibition be accepted.

After some discussion, this was agreed to unanimously. This ruled out the proposal with regard to a separate place of meeting from the exhibition hall. It was then remitted to the congress committee to make the necessary preliminary arrangements consequent upon this decision.

The Chairman read letters from the London Press Exchange and Messrs. T. and C. Bench giving in closer detail the proposals which representatives of each of those firms had sketched to the Congress for a scheme of co-operative advertising. The Chairman expressed himself convinced that the propaganda, which was foreshadowed in both these proposals, would educate the public and be of great value to photography.

Mr. Speaight proposed, and Mr. Dickinson seconded, that a small committee be formed, of quite a provisional and preliminary character, to explore the ground covered by these letters, and to ascertain what support might be forthcoming from manufacturers and dealers. This was agreed to, and Messrs. Adams, Basil, and Haines, with the President (the Chairman of Council), and Treasurer, *ex officio*, were appointed as the committee. It was suggested that Mr. Somerville might properly be consulted in the matter. It was left to the Chairman of Council to call the first meeting of the committee, which he said that he would do within the next week.

The Secretary read the various correspondence in which he had been engaged with the members, and gave an indication of the advice he had tendered under circumstances which had varied with the individual case. Among other matters on which members had been advised were:—The insurance of a motor-car; the loss in the post of photographs sent to Italy, and the question of whether the sender or the person who had ordered them to be so sent was liable; the selection of a photographic press agent (it was agreed to refer such correspondents to photographic press agents advertising in the "Record"); electric light charges (the Secretary was instructed to write again to the correspondent in this instance to learn whether anything had eventuated since her letter of October 30); a dispute over the amount to be paid by an illustrated paper to a photographer who had executed a special commission, involving the taking of three negatives., one of which was used, and payment of one guinea forwarded, although his account sent was for four guineas (it was agreed that the photographer should be advised to pursue this matter in the county court); prices for framed enlargements; inquiries for a list of members of the Association (it was agreed, arising out of this letter, that the subject of the preparation of a list of members of the Association should be put down on the agenda for consideration at the next Council meeting); a difficulty which had arisen in sending films by post, packets containing films being charged at letter rate, although prints went through at printed matter rate (the Secretary found, on inquiry of large houses accustomed to the receipt and despatch of films, that this position was generally accepted); a controversy arising out of the copyright of portraits used during the General Election (this last was the subject of two complaints from different localities, and in the case of the second, occurring at Liverpool, which had some unusual features, the Secretary was instructed to place the matter before the Honorary Solicitor); the non-acceptance by some newspapers of the agreed scale of fees for press reproduction work issued by the Association in December 1920; the use of the words "including copyright" on the receipt form on the back of a cheque sent in payment for the use of a photograph (the correspondent was advised to strike out the words, which mostly referred to literary contributions, and in the event of the bank raising any objection, to bring up the matter with his client); a question of the assessment of profits for income tax; the procedure to be taken with regard to an advertisement, the terms of which had not been fulfilled, though the advertiser was unwilling to return the money (in this case, following upon two letters from the solicitor, the money had been returned); and various other inquiries. One member had asked the Secretary to inspect, on his behalf, a business which was advertised for sale. The Secretary, although considering that this scarcely came within his duties, did so, and reported upon it to the correspondent. The Council considered that the member making the request should pay some remuneration to the Secretary for his services in the matter (as, indeed, he had offered to do), and the fee was fixed at two guineas. The Secretary also reported that he had received a number of applications from persons who wanted situations, or members who desired apprentices. If these increased it might be necessary for the Council to formulate some rule on the subject. Finally, among other unclassifiable inquiries which came his way, was one from a lady who desired him to discover the whereabouts of her husband!

The Secretary read a list of the names of new members who had been already approved, but had now paid their subscriptions, also a list of members rejoining, and of persons making application for membership. All were approved. He reported that he had a list of members who owed two years' subscription, roughly about fifty, and the Council thereupon instructed the Secretary, as had been done on a former occasion, to send a registered letter to these members, stating that if a reply was not received within a certain period, the Council would have no alternative but to strike off their names. It was agreed that a similar course should be followed in the case of those members who had not signed the form of incorporation (these, also, were members who were in arrear with their subscriptions).

Commercial & Legal Intelligence.

THE ILFORD REPORT.—The report of Ilford, Limited, for the year ended October 31, 1922, shows a net profit, after making allowance for depreciation and provision for doubtful debts, etc., of £52,235, as compared with £41,551 in the previous year. Including £6,280 brought forward there is £58,516 available, as against £52,480 last time, when £10,929 was brought in. The directors have transferred £4,000 to reserve, the same as before, and written £10,000, as against £6,000, off goodwill. They again recommend a dividend of 8 per cent. on the ordinary shares for the year, leaving £8,316 to be carried forward, compared with £6,280 brought in. As is shown by the following table, the profits for the past year show a very substantial improvement over those for any of the preceding eleven years.

Year ended October 31	Net profit.	Ordinary dividend.	Year ended October 31	Net profit.	Ordinary dividend.
	£	Per cent.		£	Per cent.
1911 ..	35,800	6	1917 ..	42,100	6
1912 ..	33,200	6	1918 ..	35,400	6
1913 ..	32,800	6	1919 ..	45,200	8
1914 ..	22,900	4	1920 ..	44,100	8
1915 ..	27,300	5	1921 ..	41,600	8
1916 ..	48,000	6	1922 ..	52,200	8

The figures for net profit for 1916 and subsequent years are after deduction of taxation.

It must, however, be borne in mind that in 1919 the capital of the company was increased from £380,000 to £500,000, by the creation of 120,000 ordinary shares.

NEW COMPANIES.

ANGLO AND OVERSEAS PRESS AGENCY, LTD.—This private company was registered on November 20, with a capital of £100 in £1 shares. Objects: To carry on the business of press agents, etc. The first directors are:—E. Brooks, 78, Hazlewood Road, Putney, S.W., court photographer; F. V. Conolly, 48, Lorne Road, Stroud Green, N.4, journalist.

ANGLO-HIBERNIAN TRADING CO., LTD.—This private company was registered on November 16, with a capital of £1,000 in £1 shares. Objects: To adopt an agreement with Ella Spencer, and to carry on the business of agents for and manufacturers of mouldings, glass importers and manufacturers, dealers in pictures, portrait enlargers, makers of and dealers in picture frames, dealers in artists' colours, oils, paints, paint brushes, etc. The first directors are: H. Spencer, 179, Archway Road, N. (managing director); Mrs. E. Spencer, 179, Archway Road, N.; J. Savery, 101, Stoke Newington Road, N.6. The two first-named are permanent. Qualification (except H. Spencer, who requires none), £5; remuneration, £52 each per annum. Registered office: 57, Kensal Road, Westbourne Park, W.10.

N. S. KAY, LTD.—This private company was registered on November 20, with a capital of £3,000 in £1 shares. Objects: To acquire the business carried on at King Street, Manchester, as "N. S. Kay," and to carry on the business of artists, photographers, dealers in photographic materials, fine arts, etc. The first directors are:—N. S. Kay, 7a, Cambridge Road, Southport, artist and photographer; R. R. S. Kay, 7a, Cambridge Road, Southport, photographer. The said N. S. Kay is permanent director, subject to holding 500 ordinary shares. Qualification, 10 ordinary shares. Registered office: 1, Ridgefield, off King Street, Manchester.

News and Notes.

CHEMISTRY OF GELATINE.—In the leading article on page 707 of the issue of November 24 the concluding sentence of the last paragraph but two in the second column should have read: "The greater the hydrion concentration of the solution, the less is the nomerical value of the p_H."

A CAMERA CLUB IN EDMONTON, ALBERTA.—The Edmonton Camera Club has recently been formed, with its headquarters in the Y.M.C.A. Building, Edmonton, Alberta. The president is V. C. Rayment, and the secretary A. C. Fleming. The membership at present is 30. A full programme has been arranged for the forthcoming season and includes a series of fixtures dealing with the elementary processes of photography. The society will be pleased to hear from firms of manufacturers and dealers in Great Britain, with particulars of new goods which they may be bringing upon the market.

WIRELESS CONTROLLED AERIAL CAMERAS.—A new method of obtaining aerial photographs, in which the human hand of the operator is replaced by wireless, is (says the "Daily Mail") now being experimented with by the United States Army Air Service. A small kite-balloon carries up with it a camera controlled through wireless means by an operator seated at a switchboard on the ground below. Not only can the camera be made to take photographs of what lies directly beneath it, but the operator on the ground can turn the camera in any direction desired. Thus, in war, without any risk of life, it will be possible to photograph a wide area of territory by wireless cameras high in the air, and at a considerable distance from their concealed controlling points.

A PHOTOGRAPHER OF ONTARIO.—There is at present in London, on a visit which is likely to extend to some months, Mr. W. James, of Toronto, who, during the past sixteen years, has developed a unique business as a news and commercial photographer in Toronto, Ontario. Mr. James has made during this period a collection of negatives running into many thousands and forming a most complete record of industrial, social and commercial life of Ontario, as well as of its many scenic attractions. His photographs have been very largely used in the Canadian and English Press, and have also been employed by him for the illustration of lectures on various aspects of Canadian life and industry. Moreover, Mr. James has been a prime mover in the establishment of the Canadian Press Photographers' Association, and as an Englishman who left this country to seek his fortune in Canada, has always taken a keen interest in the extension of the sale of British-made photographic requisites and apparatus in the Dominion. During his stay in London he hopes that he may perhaps be of some assistance to British firms in connection with the sale of goods in Canada. He may be addressed c/o the Press Photographic Agency, 3, Johnson's Court, Fleet Street, London, E.C.4.

HAND MOVEMENTS RECORDED BY THE CAMERA.—"Working by rhythm" is a subject increasingly important. Factory workers, it has been found by the National Institute of Industrial Psychology, fall into the rhythm of their machines. If the rhythm is slow, the output is impeded. The Institute intends to go fully into the matter, and the camera is being employed to picture the hand movements of workers. It is stated that "It does not always happen that a shorter series of movements is less fatiguing than a longer one. In the packing of sweets a certain process took two seconds with three stoppages and three changes of direction of the hand. A new method was found involving a continuous curve. Although the movement was slightly longer, the time taken to performer the operation was reduced." Various methods are used by the investigators to discover the flaws in efficiency of work An electric light is sometimes fixed to a ring on a worker's finger and the path of light made as his hand moves is photographed. The difference between the movements of a good and an inferior worker can thus be detected. A method of measuring the distance of a movement is to place a board marked out in squares under the worker's feet, or behind his arm when photographs of the movements are being taken.

PHOTOGRAPHIC PORTRAITURE IN TURKEY.—Travellers in the Near East have for many years been telling us of the Turk's objection to the camera, mainly because of a paragraph in the Koran—written somewhere about the year A.D. 630—prohibiting the making of living things "with souls," and promising the portrait-maker the most terrible punishments after he has left this world. Many English people (writes a correspondent who once resided in Turkey) must therefore have been surprised to see reproduced in the daily papers of last week excellent camera portraits of Sultan Mohammed VI. of Turkey, who left Constantinople secretly and took refuge on a British ship. As a matter of fact, the Koranic law has always been something of a dead letter, for although high officials in Turkey were rather slow in taking to the camera, the Turkish man-in-the-street never had any real objection to visiting a photographic studio. It has been stated that it is only since the Revolution of 1908, when the old *régime* was overthrown, that the camera has won its way into Turkey, but this is incorrect. Even Abdul Hamid faced the camera several times, and some excellent negatives of him, taken at his Palace, were in existence in 1897, and further, one of his sons in that year freely used an English-made camera in Constantinople. "Twenty-five years ago the leading photographic studio at the Sublime Porte was almost as well fitted up as a London West End studio; the proprietor, however, made the dry plates he used.

PHOTOGRAPHING THE EX-KAISER.—In spite of the many difficulties photographers meet with when attempting to photograph scenes of the ex-Kaiser's life at Doorn some workers manage to get fairly good results. Last week the Gaumont firm issued a good series, and the following story concerning them is told by a writer in "The Star."

"The pictures were taken by Baron de Radowitz-Nei and by the painter Beumme, who was the Kaiser's official photographer before the war.

"A plan was then concocted. Wilhelm was persuaded to receive a deputation of 'The Order of St. George,' a non-political association of gentlemen of birth of the old Empire, of which Radowitz was a member.

"The deputation arrived at Doorn, and the ex-Kaiser, although he gave permission for photographs to be taken in and around the castle, would not give permission for photographs to be taken of himself.

"Eventually the deputation met the ex-Kaiser, and Beumme was carrying a large Kodak camera; the ex-Kaiser again emphasised his dislike of being photographed. In the background, however, Baron de Radowitz had a camouflaged film camera. It had been explained to Baron Landsberg (who knew nothing of the plot) that this machine was an apparatus for developing photographs, and the Baron passed this information on to the ex-Kaiser.

"No attempt was made to take photographs at this moment, however, but after the ex-Kaiser had left the deputation the photographers got busy, ostensibly taking pictures of the park and castle, and the faked camera, fitted with a long-range lens, was brought into operation as soon as the ex-Ksiser was far enough away not to be able to detect it."

Correspondence.

WORKING UP SKETCH NEGATIVES.

To the Editors.

Gentlemen,—Referring to the instructions on the working up of the negative, pages 7 and 8, "Sketch Portraiture," I may say that the "Seccotine" medium therein described may now be discarded by those who have access to the Aerograph.

Possessing the same characteristic qualities of effect—but of a

different composition a composition which has the great advantage of rapid drying. "Deleto," a commercial preparation marketed by the Aerograph Co., Ltd., is, in my opinion, of an eminently practical and superior nature: it offers, in use with the Aerograph, still greater possibilities of control in that it may be used for the purposes suggested, in the manner referred to, much more effectively.

Yours faithfully,

November 22. J. SPENCER ADAMSON.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5 cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

J. E.—The stain appears to be due to contact of the prints with iron rust, probably from a metal tank or dish. It could possibly be removed by soaking the prints for a few seconds in dilute hydrochloric acid solution, 10 minims of strong, pure acid in 1 ounce of water, and washing well afterwards.

A. E. S.—The "Focuslite" will be very suitable in your enlarger. Another lamp which would be found of use is the Ediswan "Pointolite," obtainable from Messrs. Edison Swan Electric Co., Ltd., 123-125, Queen Victoria Street, London, E.C.4. You could use the latter without a reflector, as the light comes from one side of the filament only. Flashed opal may be obtained from Messrs. James Hetley & Co., 35, Soho Square, London, W.1.

A. T.—Without having enlarged the negatives we think the definition should be better than it is if a first rate f/6.3 anastigmat has been used. At the same time several of the negatives are not as free from veil as we should expect them to be from what you tell us of the ideal conditions under which the exposures were made. Nevertheless, on the evidence, we think you might be reasonably justified in asking for proof that the lens can produce better results than those which you have been able to make.

P. G.—See the "B.J. Almanac" for the formulæ for red, green and other tones on bromide or gaslight papers, which are of chief value. There have been endless formulæ published from time to time, but very few of them are of any practical use. We suppose that by "zincograph" you mean the making of line blocks on zinc. It is scarcely possible to learn this process from a book, but a manual which should be of use to your friend is "Photo-Mechanical Processes," by W. T. Wilkinson, published by Messrs. Loxley Bros., Ltd., 19, Cursitor Street, London, E.C.4., price 4s.

W. G.—Pyro caustic developer with a 10 per cent. solution of pyro may be made as follows:—

A.	Pyro	1 oz. (480 grs.).
	Soda sulphite	3 grs.
	Water to	10 ozs.
B.	Caustic potash	200 grs.
	or	
	Caustic soda	140 grs.
	Water to	10 ozs.

For use mix 2 drs. A. 2 drs. B. and 2½ ozs. water. The factor could be taken as 8.

H. F. H.—From your floor plan we do not think the windows will help you much unless you actually include them in the studio. You could probably, in your present suggestion, include a little more length in the studio by taking the partition the full length of the shop, using the opposite end for the background. You could remove the present door at the camera end and hang a curtain to cover the opening. Two 3,000-c.p. half-watt lamps would give you plenty of light, and if these were upon standard fittings you could place them where they were most needed. These would hardly be enough light for children, but you could easily fit another lamp near the wall of 2,000 to 3,000 c.p. and so get sufficient light.

HANKSON.—(1) The best book on general cinema work is the "Kinematograph Handbook," by Colin Bennett, published by Messrs. E. T. Heron & Co., Ltd., 9, Tottenham Street, London, W.1. For a weekly cinematograph paper, see the "Kinematograph Weekly," published by Messrs. Odhams, Ltd., Long Acre, London, W.C.2. (2) Cinema Traders, Ltd., 26, Church Street, Charing Cross Road, London, W.I. (3) For development of negative or positive film a very good firm is the Kay Film Printing Co., 5-6 Red Lion Square, London, W.C.1. (4) Cinematograph film is supplied by Messrs. Kodak, Ltd., Kingsway, London, W.C.2, and Messrs. Criterion, Ltd., Stechworth, Birmingham, in both cases both positive and negative.

W. J. M.—It is rather difficult to explain the cause of your trouble from the prints alone, the negatives would probably tell more. However, it looks very much as if some trouble was caused by the rack in which the plates are placed, probably by the action of the developer, especially if strongly alkaline, upon the metal of the rack. When development is complete the plates should be removed from the rack before fixing, otherwise some developer would be held by the grooves and so continue its action upon the plate while in the fixing bath. We should advise the removal of the plates from the rack, and that fixing should take place in a flat dish. Again, the fault may occur after drying if the plates are still kept in the rack, owing to water collecting in the grooves and so slightly intensifying the negative.

R. G. C.— (1) If not in quite small quantities, from Messrs. S. Guiterman & Co., Ltd., 35-36, Aldermanbury, London, E.C.2. If you only want a little, no doubt you could get it through Messrs. H. Rheinlander & Son, Rodney Road, New Malden, Surrey, who supply the extra thin celluloid used for facing, and no doubt could obtain for you material of greater thickness. (2) You can get flashed opal from Messrs. James Hetley & Co., 35, Soho Square, London, W.1. (3) An enclosed arc, such as the Westminster, should work excellently in a condenser lantern. Your failures may perhaps be due not to the type of lens, for the Petzval is quite suitable, but to the use of too short a focal length of projection lens for the condenser fitted to the enlarger. If the condenser is anything above 5 inches, a projection lens should preferably be not less than 7 or 8 inches, and, better, 9 inches. (4) We think you will not be able to get the back lighting you want with a single lamp and Barkay reflector. You should try using a lamp and reflector at an angle of about 45 degrees to the axis of the lens and on the far side of the sitter in conjunction with, say, a 1,000-c.p. lamp somewhat to the front of the sitter and placed sufficiently towards the camera to give a fair amount of detail whilst not overcoming the back lighting effect. (5) We suppose you mean by this question that you get too large and strong a flood of light in, say, a head and shoulders portrait. If you want something approaching the spotlight effect you might try inserting a diaphragm a little distance in front of the Barkay reflector, but even then you will not get an effect equivalent to the use of a proper spotlight.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3266. Vol. LXIX. FRIDAY, DECEMBER 8, 1922. Price Fourpence.

Contents.

SUMMARY.

The volume of the "British Journal Almanac," for 1923, will be published throughout the United Kingdom on Thursday next, December 14. (P. 743.)

In the concluding portion of his paper on the direct and transfer Bromoil processes, Mr. Chris. J. Symes deals at length and very completely with the inking of the image, and has a great many hints to give on the causes which lead to difficulty in this part of the process. (P. 738.)

Mr. H. Kenway, in a letter, gives his practical experience of papers specially suitable for the Bromoil transfer process. (P. 747.)

In a leading article we deal with one or two of the items in Bromoil technique to which the special attention of beginners in the process may advisedly be directed. (P. 734.)

In his presidential address before the Royal Photographic Society, Mr. W. L. F. Wastell traced the evolution of the lantern slide from the painted transparencies of the seventeenth century or earlier to those which have been made from almost the earliest days of photography by one process or another, as these latter have come into use. (P. 735.)

At the Royal Photographic Society, on Friday last, Mr. Lewis E. Banfield drew a vivid picture of the almost insuperable difficulties of dark-room work in India. (P. 744.) On Tuesday evening last Mr. Lewis Hind delivered a lecture in which he considered, with great sympathy and insight, the claims of photography to be an artistic medium. (P. 745.)

At Croydon last week Mr. J. M. Sellors demonstrated (partially, for lack of time) a system for the rational exposure of bromide paper in printing or enlarging. It is hoped to obtain a more precise account of the system later on. (P. 745.)

The prospectus for next year's Photographic Fair, at the Holland Park Hall, London, W., has now been issued. (P. 733.)

We seriously question the immediate advantage of sales of wireless goods by photographic dealers, and still more the wisdom of such a policy for those who take a long view. (P. 734.)

We regret to record the death of a veteran professional photographer, Mr. John Terras, of Markinch, Fife. (P. 740.)

Further particulars of the failure of an enlargement company, which spread its business by profuse appointments of branch managers, are given in "Commercial and Legal Intelligence." (P. 746.)

Methods of preparing a printing surface of hardened gelatine from which impressions in dyes, etc., may be taken for use as lantern or cinematograph transparencies are described at length in a recent patent specification. (P. 741.)

A method of eliminating the dot structure in the copying of half-tone proofs is described by a correspondent. (P. 747.)

EX CATHEDRA.

Lord Carnarvon's Find.

Photographers will, we are sure, derive a great satisfaction in reading of the important discovery made by the Earl of Carnarvon on the site of the ancient Thebes. For sixteen years past Lord Carnarvon has taken an active interest in Egyptian archæological research, and the discovery of the treasure which has lain undisturbed for, presumably, more than five thousand years, is a reward upon which he is to be most cordially felicitated. It must have been a moment never to be forgotten when the chamber and furnishings of the tomb of the Egyptian ruler, Tutankhamen, were disclosed to view, and were found to include, not only great treasure of gold, but furniture, clothing, and even manuscripts, which it is to be thought will throw much new light upon the history of the Egyptian kings. Dr. Alan Gardiner, one of the greatest authorities on Egyptian archæology, has expressed the opinion that the discovery seems to be one of the greatest which has been made during the last thirty or forty years; and it is hoped that many of the objects which have been found will be available for enriching the collections of Egyptian antiquity in this country.

* * *

The 1923 Photographic Fair.

Mr. Arthur C. Brookes has now issued the prospectus of next year's Photographic Fair to be held from March 15 to 21 at the Holland Park Hall, London, W., upon the acquisition of which building he and the exhibitors are to be congratulated. The hall is a spacious building, accommodating, on the ground floor, more than twenty stand spaces, ranging in area from 726 to 1,320 square feet. These represent accommodation for exhibits which is approximately three times that which was available at the Horticultural Hall; and, in addition, there is a gallery which can be used for the exhibits of retail traders, demonstrations of processes and other attractions. The new premises thus afford the opportunity for an exhibition upon a scale in correspondence with the importance of the photographic industry; and the prospectus states that many of the former exhibitors have already notified their desire to occupy larger spaces. As was announced in our issue of last week, the Professional Photographers' Association will hold a Congress during the period of the Fair, and space will be reserved at the Holland Park Hall for their members' use as a Welcome Club. Next year's Fair thus maintains the tradition which prevailed for a number of years in Vincent Square. The full prospectus, plan of the floor and gallery and conditions of exhibition may be obtained on application to Mr. Brookes at Sicilian House, Southampton Row, London, W.C.1. Among the conditions is one that goods of German manufacture will not be permitted to be exhibited on any of the stands.

The Care of Glassware in Winter. Nearly everyone has experienced the annoyance of breaking a bottle or measure, through filling it with too hot water, and it will be found that most of these disasters take place in the winter when the glass is usually at a much lower temperature than it would be in the summer. Cheap badly-annealed glass is naturally more liable to breakage than that of better quality, but even the latter is not proof against careless treatment. The chief thing to be avoided is pouring any considerable quantity of hot liquid into a cold glass vessel and allowing it to stand still. In such an operation as dissolving soda sulphite there is little risk of breakage, even of an ordinary spirit bottle, if the hot water is added a little at a time, and the bottle well shaken so as to allow the whole surface to be warmed evenly. When using measures, a hint may be taken from the man who makes whisky toddy. He first rinses the glass to be used in hot water, pouring it away before there is time to fracture, then pouring in the quantum of hot water and finally the spirit. Read sulphite for spirit in the case of a photographer.

* * *

Wireless Goods. There are probably many dealers in photographic requisites at the present time who are moved by mixed feelings regarding the question whether they shall take up the sale of wireless apparatus. It cannot, of course, be gainsaid that there is, at the moment, an interest on the part of a section of the public in these goods, and that the sale of them will usefully yield a profit which compares favourably with that obtainable on cameras and materials for photography. Yet it may be very seriously questioned whether immediately or in the long run the sale of wireless apparatus will do the photographic dealer any good. We may cite, in confirmation of this view, the experience which a well-known dealer recently related to us respecting a similar boom of some years ago, namely, gramophones. When these latter articles were as great a novelty as wireless receivers are to-day, our friend invested largely in them and made them a prominent line of a business which previously had been solely photographic. Although ample sales were made of the machines and records, it was found at the end of the year that the profit worked out no better than in the preceding twelve months. What had been gained in the sales of the new class of goods had been lost by the smaller proceeds from the photographic articles.

* * *

To the Egress. There is, however, another and a broader aspect of this question. It is undeniable that wireless is a pastime which is a competitor with photography. It may be argued that it is a hobby more especially for the winter months, whereas photography is for the summer; but, on the other hand, a great deal of propaganda has been expended by many of the manufacturing firms in the amateur photographic trade for the purpose of maintaining sales on photographic goods through the winter months by demonstrating the opportunities for interesting work which are to be found in flashlight, enlarging, lantern-slide making, and other branches. In so far as wireless goods are offered in shops which essentially are those where photographic requisites are sold, the effect is to detach photographers from their hobby and to turn their favours in a different direction. And if that is done, there is no saying that they will return to their former interests. In short, it seems to us that, so far as photography is concerned, a share in the dealing in wireless apparatus is unwittingly fulfilling the purpose of the device which was credited to the late Mr. P. T. Barnum, who labelled a door within his exhibition "To the egress." Visitors who made use of it found themselves outside the premises. Considering how much has been done by firms large and small to make recruits for photography, it seems a pity that for the sake of an immediate profit, the continuance of which is highly doubtful, dealers of any kind should take part in a trade which offers a substitute for the proved attractiveness of photography.

BROMOIL PROCESSES.

THE article by Mr. C. J. Symes on another page is a reminder that undoubtedly the most interesting printing processes we have to-day are the allied methods of Bromoil and Bromoil transfer. Very beautiful effects, equal to old mezzotint engravings, can be obtained with a minimum of trouble, while the ease of control is equalled by no other printing process. The possibilities of these processes for pictorial portrait work have not been fully exploited, and we feel sure that the man who makes himself a proficient Bromoil worker, will find good reward for his labour. Comparatively, few workers, however, are tempted to try the processes, mainly because of the supposed difficulties. But if a thorough appreciation of the details of Bromoil and its transfer are first obtained, before attempting work the difficulties of the process largely disappear.

The process really begins in the obtaining of a suitable negative, and from the making from that of a suitable bromide print or enlargement. So many workers fail because of this early stage being neglected, but it is impossible to expect a good Bromoil from a weak, washed-out bromide print. What is required is a print which would be called a perfect example of the process, from the standpoint of subsequent sulphide toning.

To turn to the bleaching bath, many formulæ have been published, most of them excellent, but it is the same with this solution, as with developers. It is necessary to keep to one good formula and to become familiar with its action. The temperature at which bleaching should take place varies with the various formulæ for bleachers. This is an important point in the process. On no account should a bleaching solution be used warm if intended to be used cold or *vice versâ*. It may be presumed that the worker who has suggested a formula knows best how his solution should be used. Yet many of those working the process are very slipshod in this respect. We have seen, personally, prints transferred from hot to cold solutions and then back again into hot water without any idea of the failures that the change of temperatures may cause. If a bleacher has to be used warm, then the wash water and fixing bath are invariably to be used at the same temperature, and any variation will lead to failure. The gelatine emulsion of a bromide print is a very sensitive substance as regards variation in temperature, especially when wet, and blisters are easily caused if manipulation is careless in this respect. We have heard it said that draughts of hot or cool air in the room in which the Bromoil is being made cause uneven inking, and may possibly spoil the print, but we doubt whether the process is quite as delicate as this.

It is most essential that the fullest attention is paid to all the small details of the process; it is the little things that make or mar the perfection of the result. The utmost cleanliness must be observed at every stage, from the making of the bromide enlargement to the drying of the finished Bromoil. Dishes and measures must be scrupulously clean. Brushes must be free from

old dried ink, and dust must be eliminated as completely as possible. All materials should be cleaned immediately after using and put away ready for the next time they are required.

The subjects most suitable for these processes of printing are those depicting fairly strong effects of lighting. The flatter type of lighting does not always show to advantage, and should not be attempted until the worker has become fairly proficient, and able to exercise a fair amount of control over his inking. We should advise the beginner to choose some simple subject having a fair amount of light and shade. The contrasts would therefore be on the strong side, and would give the worker a chance to acquaint himself with the control in printing which is open to him. Again, we think the best size of print for a beginning should be half-plate. With larger sizes there is greater difficulty in following the idea of the picture, and more liability to get grainy, uneven shadows, owing to faulty brushwork. Also, the attempt should be made not to ink up too large a surface at once. Let the subject be covered up as pigmenting proceeds, and so yield a perfectly even deposit. The quality of the brushes and ink should always be of the very best. Only the actual inks manufactured for the Bromoil process should be used. Printing and lithographic inks may be of use to an expert who has some experience in the particular ink he is using, but for the beginner only the special Bromoil ink will prove satisfactory.

THE EVOLUTION OF THE LANTERN SLIDE.

[The presidential address, delivered recently by Mr. W. L. F. Wastell before the Royal Photographic Society, concerned an historical subject which for some reason or other has not previously been dealt with at all thoroughly. Even the voluminous German and Austrian writers on the development of photography have very little to say on the stages through which the lantern slide has passed. Mr. Wastell traced its evolution from the pre-photographic transparencies, and followed his discourse with the projection of more than one hundred transparencies representing the very many printing processes which have been employed in their day for the making of lantern slides.]

It is my desire this evening to try to bring together, I believe for the first time, a few salient facts in the evolution of the lantern slide. To the lantern itself I shall refer only incidentally, although it is obvious that without the projection lantern there would have been no necessity for slides of any kind; but it is of the slide itself, in its many forms, that I shall mainly speak.

A ray of light passing through a tiny hole in the shutter of a darkened room will form on the opposite wall an inverted image of part of the scene outside, and from this fact was derived the familiar camera obscura—a darkened room. Its invention is generally attributed to John Baptist della Porta (partially to anglicise the name), who was born in Naples in 1547. While he was a boy of 16 or 17 he published an extraordinary book, "Magica Naturalis," in which he describes his use of a convex lens to sharpen and brighten the image in the camera obscura. But he did more. Instead of relying only on the image of objects within range of the lens, he made drawings on transparent material—some of them with movable parts—and the results he thus secured were so mystifying that the term "magic lantern" arose—a term used later by Sir David Brewster in 1831. It is surely in these transparent drawings of Della Porta that we find the prototype of the lantern slide.

The method of obtaining images in a box or tent probably suggested to Athanasius Kircher the lantern which he evolved somewhere about 1640, of which I shall show an illustration later. It was a sort of inversion of the camera-obscura method. The light itself was enclosed in a box or chamber, and the image on a transparency projected by a lens in a darkened room.

But it is supposed by some that the use of such a lantern is suggested still earlier by Benvenuto Cellini (1500-1570) in his account of a séance given by an Italian priest. He says:—"After the usual ceremonies and incantations indulged in on such occasions, which were performed by the feeble light of a fire, in which an assistant from time to time threw various perfumes, innumerable troops of devils appeared." After this display Cellini and his companions declared that they saw similar apparitions of devils in the streets on their homeward journey, but such statements must be accepted with caution. Some people see strange things late at night. It is quite possible that the effects at the séance were produced, not by any form of lantern, but by the use of a concave mirror, which was used for similar purposes in Greek and Roman times.

However this may be, it is certain that a "lanterna magica" with two convex lenses was seen and described as early as 1655, and under date of August 19, 1666, Pepys says in his Diary:—"Comes by agreement Mr. Reeves, bringing me a lanthorn, with pictures on glass, to make strange things appear on a wall. Very pretty." This is just the sort of thing that would appeal to Pepys, and it is not surprising that a few days afterwards he bought both the lanthorn and a telescope from Mr. Reeves (who was a telescope maker), paying him £9 5s. for the two. The effect of the use of this lantern in public we shall see presently as the subject of an old French print.

For close on 200 years after this the hand-drawn and hand-coloured transparency held undisputed sway. Moving slides and chromatropes were introduced in 1841, and dissolving views, by the use of two lanterns, in 1846. For the so-called dissolving-view effects a triple lantern was often used later, and at the old Regent Street Polytechnic, which boasted the finest lantern-room in the world, as many as six lanterns were sometimes brought into play.

It is impossible to show any of these effects with a single lantern, but a description of them can be understood, if it is remembered that slides were produced in sets, and the lights to the lantern manipulated so that one image faded away as another was illuminated, or that the image on the screen was a combination of two or more slides in the lantern. The description is taken from the 1891 edition of Lewis Wright's "Optical Projection". "Let us suppose an English landscape, with a windmill, and millpond in front. (Query, Why a millpond for a windmill?) It may be first thrown on the screen in the fresh green of an English spring. Presently the mill turns round, then the scene dissolves (without appearing to change) into the warmer hues of autumn, and one or two swans glide gently over the glassy lake. The scene dissolves again into a tempestuous night, the sky covered with clouds, and little light getting through from the partly turned-down lantern. Flash after flash of lightning breaks across the dark sky, followed by peals of thunder (produced by shaking a square of sheet iron), and finally a rain slide is thrown on the scene, the sound of the storm being well represented by

pouring some barley into an appropriate vessel, and a flash or two of lightning being still continued. Finally these effects are changed for one showing the moon emerging from behind a cloud. This must be done very gradually; and while the moon slide is thus worked the scene is gradually dissolved into a bright moonlight scene, with the light upon the water. After a few moments a snow slide is put in; and when this has fallen for a few seconds, the landscape is again dissolved into a winter scene, with snow upon the landscape and ice upon the pond, on which skaters execute their gliding movements; or this last may be done when the scene is again changed to a night and bonfire effect with lights in the mill windows."

This glowing description certainly indicates an advance beyond the state of things suggested by a definition in an old dictionary:—"The magic lantern is a small optical instrument which shows, by a gloomy light on a wall, monsters so hideous that those who are ignorant of the secret believe it to be performed by magic."

Such dissolving and mechanical effects as the one described could be produced only by considerable skill in the preparation of the slides, good sets of which cost many pounds. It was difficult, too, to centre all the slides accurately on the disc, and at least two operators were required to manipulate the slides and lanterns, with an additional one to produce the incidental noises.

For a long time the usual method of producing a hand-drawn slide was as follows:—The outline was first drawn on a sheet of paper. Over this was laid a piece of clean glass, on which the outline was traced in black or colour, with a fine brush. When this was dry, transparent oil-colours were applied, dabbed smooth in some parts with the tip of the finger—pumice-stoned smooth for the purpose—and wiped or scraped away in other parts. The slide was then baked for hours to dry this first painting, after which further work was done, until with alternate baking and colouring, the slide was finished. Many of the better class slides were solidly painted, without any definite outline at all.

It was not till the middle of the nineteenth century that the first whispers were heard as to the possibility of photography being applied to the production of lantern slides.

The photographic process to which Daguerre's name was given employed a plate of silvered copper for producing the image, and the Calotype process of Fox Talbot gave both negatives and prints on paper. It was manifestly impossible to use opaque or even semi-opaque media for lantern projection. In 1848 Niépce de St. Victor published his method of producing photographs on glass plates coated with albumen and sensitized with silver, and this process was rapidly improved by Blanquart Everard and Le Gray. In 1851 Scott Archer evolved the wet-collodion process for both negatives and positives.

It is evident that by this time there were two photographic processes suitable for the production of slides for projection, yet in Hunt's 1853 edition of his handbook on photography there is no mention of such slides, and in 1854 a member of the Liverpool Society said that collodion transparencies would be useless for the lantern, while another member added that they were too transparent.

The "Manchester Guardian," however, records that in the autumn of 1853 Mr. J. B. Dancer gave an exhibition at his house of what was was called "microscopic photography," which it is clear was nothing but the projection of photographic transparencies. Amongst his audience was Mr. Hutchings, the secretary of the Mechanics' Institution of Manchester, and during the winter he arranged for the exhibition at the Institution of both photographic and hand-coloured slides. The latter were pronounced to be markedly superior. The following year the methods of slide-making and limelight projection were so improved that large audiences were attracted to the regular exhibitions, and the Institution made a yearly profit of about a thousand pounds. In 1859 "Chamber's Journal" described how 20-ft. pictures were being shown at the Institution to hundreds of people, and suggested the value of such exhibitions for educational purposes. Inquiries as to the methods employed poured into the Institution from all quarters, and the year 1860 may be named as the approximate date which saw the photographic lantern slide firmly established. Thus did Manchester show the way to the Polytechnic.

In the 1856 edition of Winsor and Newton's manual on "The Art of Transparent Painting on Glass," it says in the introduction: "In the use of painting on glass photography will be found an invaluable aid. Photographic pictures themselves may be thrown on to the disc; but the advantages and facilities which photography presents in obtaining accurate views of sites, buildings and objects, cannot be too highly estimated."

Thomas Sutton, the editor of "Photographic Notes," writing in February, 1856, suggests projection of two stereoscopic transparencies by two lanterns, or that an artist might make tracings from such, and colour them. (Here, as in Winsor & Newton's book, is a distinct suggestion to use actual photographs.) Spectators were to have a pair of spectacle frames fitted with small vertical prisms, so as to displace both pictures sufficiently to make their central lines coincide, and form a single picture with stereoscopic effect.

In the same year, 1856, the experiment was tried at the Photographic Society of Glasgow, using Ferrier and Soulier's stereo slides. The viewing stereoscope was of Parisian make, and the spectators had to vary their distance according to the degree of enlargement.

It is interesting to find at such an early date the problem of optical stereoscopic projection was being investigated; but here a more important point arises. We must remember that a large proportion of early photographers used stereoscopic cameras, obtaining pairs of negatives each 3¼ inches square. When the first attempts were made at producing transparencies for the lantern, these were printed from one of the stereoscopic negatives; and I suggest that it was this fact that has given us our standard English lantern size of 3¼ inches square. The hand-made slides were of all sorts of sizes. Circles of 3 to 6 inches diameter were common, and some of the Polytechnic slides were 8 by 5 inches, and even larger.

In February, 1857, Mr. C. I. Burnett read a paper before the Photographic Society of Scotland in which he suggested some strange uses for the new photographic transparencies. "It may sound very odd to talk of smoke or vapour as a photographic canvas, but very startling effects might no doubt be produced by throwing the image from glass positives, placed in the magic lantern, on wreaths of smoke or vapours. Such an apparatus would have been quite a godsend to the conjurors of old, and might, even in our enlightened nineteenth century, prove invaluable to the explorer among savage tribes. To solitary explorers it would be no small advantage to be able to conjure about them at night such a host of ghastly protectors as this would enable them to exhibit to their watchful foes." As a matter of fact, this method of projecting ghosts, skeletons, and other cheerful subjects, had been tried long before, for I have seen in a work published in 1794 instructions for making a special smoke-box for the purpose.

Mr. Burnett had another brilliant idea: "Might not the images from glass positives be made available for the exhibition of scenery in our operas and theatrical performances in certain cases? We need hardly say how superior such scenery would be to much of what now accompanies our operatic and theatrical performances." This is certainly a scathing commentary. What must the scenery have been like

if the photographic transparencies of the 'fifties were an improvement on it? Had the views been projected from the front, it is obvious that the performers themselves would have been covered with the photograph; and if from the back, the light from the footlights would have counteracted that from the lantern.

After Mr. Burnett's paper there was an exhibition of 24 slides illustrating an expedition to Teneriffe. The lantern was fitted with what was known as a limeball light, and the screen used was only 6 feet square.

In September of the same year (1857) "Photographic Notes" published the following letter from Mr. John F. Dudgeon, of Glasgow: "I take what is termed a common negative plate, in the usual way, and from that negative plate I take another plate which is termed a transparency, because in looking through it you see the person or object as it is, or in short in its positive or real form. This transparent plate I may colour (with transparent colours, of course), or not, as I please. If not coloured, it gives to the picture on the white curtain, when exhibited in the magic lantern, nearly a pure white and black appearance. If painted according to the person or object taken upon the plate, the same is seen on the curtain or canvas. I next pass this plate through the part formed for it in the lantern (*i.e.*, between the gas-jet or lamp producing the light, and what is termed the bull's-eye), and the exact image of the plate so presented in the lantern is immediately transferred, so to speak, to the tight canvas or curtain."

Mr. Dudgeon was suggesting that this projection of a lantern slide, plain or coloured, would enable an artist to paint a portrait without compelling the sitter to pose to him for weeks. But the editor pointed out that the canvas would have to be semi-transparent; that the artist would have to sit behind it; and that he would not then have sufficient light to paint by. Thus are the glowing fires of suggestive geniuses extinguished by douches of editorial cold water.

At this time the albumen process was used for making transparencies for the lantern, and a hint as to its character may be gathered from a letter from Mr. J. Ross (of Ross & Thompson, Edinburgh) in 1857. "The eggs are beaten up with common salt, dissolved in water, saturated, 14 drops to each egg. When coated and dried, which is done in the usual way, dip in silver, 70 grains to the ounce of water; put in the dark till dry. Expose in the printing frame from one to three hours, in sunshine, according to the strength of the negative, and fix with hypo-sulphite; wash in the usual way."

The same process, but with more sensitive plates, is mentioned in the "Liverpool and Manchester Photographic Journal" of April 15, 1858, in answer to the following letter:—"Sir,—Can you favour me with an idea as to where I shall find the process for producing photographic magic lantern slides? Such, for instance, as the beautiful subjects exhibited lately at the Manchester Mechanics' Institution. Only a month or two back I found in the 'Journal' a notice that 'small transparent pictures make good lantern slides,' but I cannot find anywhere how to produce them. I believe architectural or landscape subjects are the best for slides, especially the former, and that portraits will not answer. Can you tell me the reason of this latter fact? Excuse the trouble; your valuable advice may make something out of A. Tyro." The editor replied: "Magic lantern slides may be produced precisely in the same way as the transparent positive stereographs, that is, by bringing the negative in direct contact with excited albumenised glass plates, exposed to diffused daylight for a few seconds, and subsequently developing in the same manner as for a negative. Instead of albumenised glass, the dry collodion process of Dr. Hill Norris, or the collodio-albumen of M. Taupenot, may be substituted with advantage, especially by the amateur. We do not agree in the proposition that portraits will not answer in the magic lantern."

We may note that the wet collodion process, invented by F. Scott Archer, was now being largely employed instead of albumen, mainly on account of its greater rapidity.

In an early number of the "Journal of the Photographic Society"—now "The Photographic Journal"—appear the following letter and reply:—Question: "How may one reprint from a glass negative on glass, so as to serve for the phantas-magoric lantern?"—Answer: "Probably the best means would be to take a positive copy on collodionised glass by means of Heilman's photographic pantograph. After this has been fixed and washed it is fit for a slider, showing, however, light and shade only; but it may then be coloured by hand in the ordinary way of painting lantern slides—that is, with transparent colours mixed with varnish" The grandiloquent name, Heilman's photogenic pantograph, signified nothing more than a fixed-focus camera for copying same size. Note, too that the word "slider," instead of "slide," was not uncommon at this period.

Printing by contact with wet collodion was naturally impossible; hence the use of the camera for copying. The collodion-coated, silver-sensitised plate had to be exposed as soon as it was prepared. There is a story of a gentleman who was about to expose such a plate when he was suddenly called away. His luncheon of sandwiches and India pale ale had just been brought in, and he poured a little of the ale on and off his plate once or twice. On his return he found the plate still in good condition, and thenceforth there were experiments with different brews of beer, and it became common to use also as preservatives such things as tea, coffee, raspberry vinegar, and oxymel, which was a boiled syrup prepared from honey, water, and vinegar.

Later on it was discovered that by certain additions, to prevent the collodion from becoming horny and brittle, it was possible to dry the plate and keep it for some time—a discovery that culminated in the well-known dry collodion plate of Dr. Hill-Norris. Still later, gelatine was introduced as a vehicle for the silver salts, and the modern dry-plate for both negatives and positives came into use. By employing both bromide and chloride of silver, separately or in combination, varieties of lantern plates were produced for giving black or brown tones by suitable exposure and development, and many other colours by various toning methods.

Returning for a moment to an earlier date, we find that in 1860 the plain photographic image was not always considered to be beyond improvement, as the following remarks indicate: "Delicate manipulation is necessary in the preparation of photographs to be used in the magic-lantern slides; they ought not to be heavy and opaque. Some subjects, such as florid Gothic buildings, are especially adapted for lantern slides: the details of the architecture break up the masses of colour, and produce an agreeable balance of light and shade. Other subjects require to be opened up with a etching-needle, and toned with colours to render them pleasant and effective. Any reasonable amount of labour is well bestowed in bringing a photograph into the best condition for exhibition on the screen."

Or again: "I have found the value of a photograph as a lantern slide to lie mainly in its exquisite outline and drawing, and only secondarily in its light and shade." Whereupon, accordingly, he proceeds to open it up with an etching-needle, and then colour it.

In January, 1863, Mr. Samuel Highley, F.G.S., read a paper at a meeting of the Photographic Society held at King's College, advocating the use of the photographic transparency for lantern slides in place of hand drawings, and mentioned that Messrs. Negretti & Zambra were the first in this country to put on sale for the lantern subjects of geographical and architectural interest. He suggested a

standard size of 3¼ inches square for slides, and proceeded to show some examples made with the microscope, and others copied from engravings. He was quite enthusiastic on the value of obtaining subjects from engravings, until in 1866 he was prosecuted and fined for infringing copyright. This probably converted him to the idea that it was better to obtain original subjects direct.

About this time there was a craze for adapting cameras for optical projection—with what success may be imagined; and many articles appeared giving directions for making home-made lanterns for showing the photographic slides to which so many were turning their attention. There was also a suggestion that a club should be formed for the exchange of photographic transparencies suitably mounted for the lantern.

A note in 1865, to the effect that "photographic transparencies are now steadily taking the place of the old class of painted slides for the magic lantern," suggests that it is time to pause and proceed to examine some actual slides, old and new. It is impossible to place them in chronological order, or to include more than a few types; and I should like to show first a few examples of wood-framed slides. These will not go into the ordinary carrier, which must be removed for the purpose; and when it is replaced we can glance hurriedly at some examples of plain and coloured slides of standard size.

W. L. F. WASTELL.

BROMOIL AND BROMOIL TRANSFER

(*Concluded from page* 725.)

Inking is the next process, and provided everything has been correctly done up to this point, should present no difficulty. First of all, squeeze a little ink (the hardest you have) about the size of a pea, on the palette knife and spread it as thinly as possible on the glass you are using as a palette. Then take the soaked print from the dish and place it on the plate glass provided for this purpose. While still wet, swab it firmly and evenly all over with a wad of cotton wool taking care that no grit or foreign body is on the surface: lay a piece of blotting paper over the print and squeegee lightly until all surface moisture is removed. Wipe away all moisture from the glass around the print, in order to avoid getting moisture on the brush, for, if this happens, not only will the ink refuse to take from the wet brush, but it will also remove the ink already deposited in spots. Take the largest brush and dab it lightly in the ink on the palette, holding the brush vertically and at about 2 inches from the top. Then tap the brush on the plain glass of the palette two or three times to even the distribution of the ink on the brush, and dab it lightly on the print, putting a slight pressure on the brush just as it touches the print. At no period should there be very much ink on the brush—it should only be on the very tips of the hairs. This dabbing motion, which I can only compare to the way an impatient man taps a pencil on his desk, should be continued till the ink has taken evenly all over the print and attains the depth desired. Practice soon makes the action automatic.

The chief point to remember is that it should always be gentle and as rapid as possible. The pressure that I mentioned should take place as the brush touches the print, should be the merest emphasis, and the dome shape of the brush will turn this into a dragging motion which deposits the ink. There should always be some ink on the brush except in the final stages, when it is sometimes desirable to go over the print with a clear brush to even up the result. If it is desired to remove ink, this is easily done by reversing the motion and making the emphasis of the stroke on the upward movement of the brush. This also tends to heighten the contrast.

As a rule it will be found that the hardest ink will take quite well, but occasionally it may be necessary to thin the ink a little; a small quantity of medium should be taken on the palette knife and thoroughly worked into the ink. It should be let down little by little till it will just take easily and no more. With some papers there is sometimes a little initial difficulty which goes with working, and before diluting the ink one should be quite sure that this is not the case. It is better, however, to use as hard an ink as possible, as the result is seldom clean when the ink has been softened at all, and medium should only be used when the print refuses to ink, unless, of course, it is desired to subdue insistent high lights, spots, and suchlike local alterations.

To heighten local lights a small, soft, pointed rubber may be used or a small clean brush will remove the ink if lightly hopped or bounced on the print. Hairs from the brush, bits of grit, etc., on the print should not be moved until the ink is dry, which will be in about two or three days. They may then be rubbed off or lifted with a sharp knife. High-lights may then be cleaned up with a soft rubber and spots removed. It is safer and easier to leave anything in the nature of retouching till the print is thoroughly dry.

The beginner should, however, aim first of all at producing an exact replica of the bromide print, for until he can do this he is hardly in a position to use control—he is controlled by the process, and although he may fluke an effective result, he will never know how he produced it nor will he be able to repeat.

It should be realised that this process depends upon two very unstable factors—gelatine and a chromic salt. My knowledge of chemistry is elementary, but I am informed that gelatine is still a subject for research, and until its properties are definitely established the process must remain uncertain. I can, therefore, only mention some of the difficulties I have met and overcome, and where I think I have been able to trace a cause, it is quite possible that chemists may point to other things which may give the same result or dispute my conclusions in entirety. As far as actual practice is concerned, however, I may say that I have proved all my remedies to my own satisfaction, and where I assume a cause, whilst it may be open to argument, the remedy I put forward has been effective, although it may act in a different manner to that which I imagine.

It should particularly be mentioned that in tracing faults or experimenting only *one* alteration should be made at a time, for it is obvious that if two things are tried it is impossible to say which is responsible for the difference.

The first difficulty that is usually met with is a refusal of the ink to take. Over-soaking, soaking-in and the use of solutions at too high a temperature, too large a proportion of bichromate in the bleacher, too hard an ink, moisture on the surface of the print, too lengthy bleaching, insufficient bleaching, and the omission to swab the print before inking will all cause this condition, and to deal with each in order:—Over-soaking and soaking at too high a temperature (both amount to the same thing) are indicated by an excessive relief, occasionally by blisters and sometimes, but very seldom, by the gelatine in the high-lights reticulating or coming off in little bits. Except in the latter case, there are two remedies—one is to dry and re-soak either at a lower temperature for the same time, or at the same temperature for a shorter time. The second is to let down or dilute the ink. The former is preferable, as there is less risk of getting the print oversoaked.

If the ink takes a little but will not give sufficient depth the ink is too hard and should be let down, little by little, till it will just take sufficiently. If there is too much bichromate in the bleacher, the print acts in much the same way as if over-soaked, but with these differences. If the ink be thinned so that it will take there will be no gradation in the shadows or high-lights, the ink will not stay on the print with repeated brushwork, and where it does it will be grainy in texture and poor in colour. There is no remedy. A similar state of things, though not so bad, is produced by leaving the print in the bleacher too long, but in most cases longer soaking will do much towards giving a passable print.

Too little bichromate is shown by a general reluctance to ink; if it takes at all it is patchy and easily removed, and there is no gradation anywhere except perhaps in the lighter portions of the print and it may not show there. A print in this condition is hopeless, though if it is not very much at fault thinner ink may produce a result.

If one forgets to swab the print it may be cleaned with petrol on cotton wool, dried, and re-soaked, but wherever petrol is used on a print, care should be taken to see that it has all evaporated before wetting the print again or a very muddy print will result.

It also happens that, instead of the ink refusing to take, it takes all over—on shadows and high-lights alike. This is most likely due to insufficient soaking or soaking at too low a temperature, but may be due to a too soft ink, too little time or too much in the bleaching solution, and to the use of stale paper.

If it is due to incomplete soaking or the temperature is too low—indicated by a lack of relief—clean with petrol and re-soak as above at a higher temperature for the same time or a longer time at the same temperature.

It is not very often that a print that has been too long in the bleacher takes ink indiscriminately, but if it does occur it may be deduced from the fact that whilst the whole print is too dark in tone, the quality is good except in the high-lights where the colour of the ink is poor, and if a black ink has been used, the lights will be brownish instead of grey. The lights, too, will take ink more readily than the shadows, giving what is known as partial reversal. This may be overcome by continued inking. Reversal itself is dealt with further on. There is no real remedy, but a longer soaking may give a lighter print.

Where the print is under-bleached, it usually takes the ink lightly, without regard to the image except in the lighter parts, and there it may not take at all, and is easily removed by continued dabbing as before-mentioned.

Too soft an ink is shown by the image being too dark all over with dirty lights and clogged-up shadows. The ink is difficult to remove by brushwork, and the whole thing has a muddy appearance. The print may be cleaned with petrol and re-soaked, a harder ink being used.

Stale paper sometimes both refuses to take or takes all over: in either case nothing can be done.

Reversal or partial reversal is a curious phenomenon that is sometimes met with, and no one appears to know how it arises. It can be cured, generally, by a thorough cleaning with petrol, drying, and re-soaking, and sometimes persistent inking will gradually remove it.

I have found definitely that it is due (1) to a stale bichromate solution being used, or (2) to the bromide prints not being thoroughly washed, and to (3) hypo and developer contamination, and also (4) to too great a proportion of potassium bichromate.

There may be other things which may cause reversal, but I have not been able to establish them definitely. Some fellow-workers have mentioned that they suspect working in a warm room during inking, but I have never been able to prove this, and think it more probable that one of the causes above-mentioned is responsible.

It is obvious from the foregoing that perfect cleanliness in working is essential, and the faults I have given indicate of themselves what precautions to take to do away with the nuisance of reversal.

A Bromoil sometimes works up well but the image is grainy and composed of minute dots that will not coalesce. This is generally due to a dirty brush or one with too much ink on it. The ink may be unsuitable, but as long as it is of the makes above mentioned it is very unlikely indeed.

Patches which ink up irregularly are sometimes noticed, and these may be due to several causes. If they are circular or semi-circular in shape they are most likely due to air bubbles in the first fixing, during bleaching or soaking. There is no remedy except retouching the finished print when dry, so care should be taken to use plenty of the various solutions and to see that the prints are always kept moving and under the surface.

If they are irregular in shape and lighter than their surroundings, they may be caused by the print not being covered in an even sweep in developing or bleaching; if they are darker than the rest of the print, they may be the result of soaking too many prints at a time, of sticking together in one or other of the baths, or possibly the victims of such a silly practice as pouring hot water into a dish containing prints in order to raise the temperature. In this case some of the hot water is bound to reach the prints without being cooled by the water already contained, and markings are obviously inevitable.

Temperature should always be adjusted before the prints are put in, and the dish well rocked before and after insertion. Marks may also be caused by insufficient bleaching, incomplete first fixing, not enough soaking or washing. The symptoms and remedies have been mentioned above.

Very occasionally a print will refuse to bleach, and the most likely cause is the presence of hypo in the emulsion, or the use of acid hypo in the first fixing, or the paper may be utterly unsuitable. The bleacher may be exhausted, and in the latter case only is there any hope of making a decent print; it should be removed from the dish and placed in running water till the yellow stain has gone, and should then be placed in fresh bleacher, proceeding afterwards as usual.

Other irregular markings are due to such things as touching or rubbing the surface of the print with the fingers during any of the operations, and abrasions due to improper handling, such as pulling prints out of a dish by one corner or grazing them on the edge of the dish in removing from dishes or tanks.

This process is a charming and elusive one—it is difficult—but the results, even if uncertain, are of such a quality that no other process can equal. It is not a process for the novice, and until a worker is able to turn out bromide prints of quality with absolute certainty, it is no use thinking of Bromoil, for whilst it requires a considerable amount of technique to produce a good bromide, it is nothing to that that is necessary to make a good Bromoil. Similarly, Bromoil must be mastered before proceeding to transfer.

Transfer is a process that is based on Bromoil. Up to the point of inking the procedure is similar, but thereafter there are differences.

Both bromide and Bromoil may be stronger in contrast as the print eventually produced is softer than the Bromoil.

In quality the result resembles an etching; which is not surprising when one considers that the paper and inks employed are identical, and, in addition, it has the advantage over etchings in the rendering of gradation and in the faithful depiction of half-tones, usually lacking even in the best of etchings.

Bromide papers suitable are:—

Kodak "Velvet."
Barnet "Smooth Ordinary."
Barnet "Semi-Matt Card."
Kodak "Royal."

The time of soaking and the temperature have been given

above in the Bromoil section and are calculated so as to bring the print to such a condition that it will take the ordinary stiff ink used without dilution.

It is important that it should do this, as if the ink is diluted it is reluctant to transfer. The fact that all the ink put on the print has to come off again must be kept in mind from the beginning. Inking should be as light and rapid as possible. A 15 × 12 print should not take much more than 30 minutes to ink, including faking.

Now, assuming that the print is ready on the glass slab, take a very small amount of pigment on the brush, much less than for Bromoil, and lightly dab it all over in order to see where the lights and shadows are. Ink up the lights first, then the half-tones, and lastly the shadows. The reason for proceeding in this order is that the darks are most reluctant to transfer while the lights and half-tones do so easily. The longer the darks are left before transferring the more difficult it is to transfer them.

Do not work the print to smooth down the ink more than is barely necessary, and leave all faking to the end.

If medium is necessary to thin the ink in order to darken obtrusive lights it may be sparingly used now. It is advisable that the effect desired should be memorised beforehand and kept in view all the time, so that no time is wasted thinking what to do and how to do it at the end.

Inking being complete, the Bromoil is ready for transfer. My press is an ordinary kitchen mangle—it serves as well as an etching press or the special machines made for the purpose.

Any paper made for etching is usually suitable as long as it is tough enough to hold together when the Bromoil is pulled away from it. It should be fairly thick and absorb water easily, and should not have much, if any, size in its composition. Hand-made papers are usually best.

The transfer paper requires to be in a damp, but not wet, condition when the operation of transfer takes place. At some time previous to inking the Bromoil—an hour is sufficient—take such a number of sheets of transfer paper as are likely to be wanted and soak them for not less than five minutes in water; take them out one by one, allow them to drain a little, and place each between sheets of blotting paper, i.e., put a sheet of blotting on a board, then a sheet of transfer paper, then another piece of blotting, another transfer paper, and so on. In half an hour they will be ready for use, and will remain so for some hours unless the room is unduly warm and dry.

A carrier to take the print and transfer paper should be made ready beforehand. I use a piece of 3-ply wood rather larger than the largest transfer paper used. On this I place one or two pieces of smooth card (simply to make up the thickness and increase the pressure), then the Bromoil, and on top the transfer paper, and over that a piece of printers' blanket and a thin card. The whole is passed through the mangle and afterwards separated.

In detail, after inking is finished the Bromoil is put on top of the second card of the carrier, is masked with strips of thin paper to give a straight and clean edge, the transfer paper is placed in position on top, over this the piece of printers' blanket, and then a thin piece of card, taking care that everything is quite flat or creases will result. The latter card is only to protect the print from any roughness in the roller.

Now screw up the mangle as far as it will go—it is practically impossible to get too much pressure, and pass the whole sandwich through and back. Take off the top card and blanket and turn the Bromoil print and transfer over—they will be sticking together—and mark the corners in order to get correct register in case the transfer wants more depth anywhere; lift the Bromoil print by one corner and carefully and slowly peel it from the transfer paper, watching the transfer and Bromoil to see that all the ink has come off the Bromoil. If a small patch is seen to be remaining on the Bromoil it may be replaced—taking care that it remains in register—the blanket and card put on top, and the whole put through the mangle again. Occasionally it may be necessary to make a pad of folded newspaper to increase the pressure locally where the ink has failed to transfer.

Sometimes it is sufficient to turn the print and paper halfway round and put through again.

Having parted the Bromoil and transfer, the latter should be examined to see if it is strong enough. It is far better to get the right strength with one inking, if possible, but if there is not enough depth in the transfer, the Bromoil may be re-soaked in cold water, say for 10 to 20 minutes, and re-inked only in those places that require more strength. Put the print in register on the transfer and put through the mangle again. Repeat if necessary but don't overdo it, as the transfer paper will be drying all the time and the gelatine of the Bromoil will probably get tacky, in which condition it will pull off the surface of the transfer paper.

If another transfer is required the Bromoil may be cleaned with petrol, dried and re-soaked as before mentioned, re-inked and re-transferred.

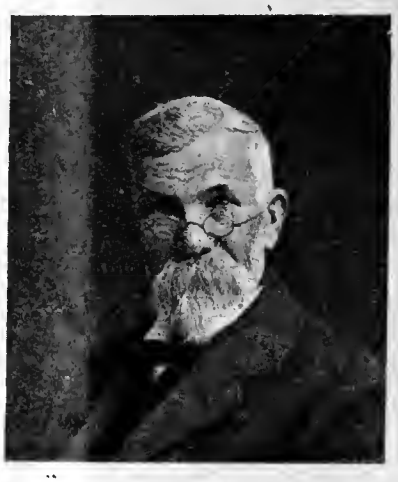
This may be repeated till the surface of the Bromoil gives out—it is possible to get as many as six or seven transfers from the one bromide print, but the quality deteriorates rapidly after the second. Re-touching may be done to almost any extent when the transfer is dry. Carbon pencils, Bromoil ink diluted with paraffin, water colours, chalks, india-rubber, and a sharp knife may be used as the skill and fancy of the operator directs.

Care is essential throughout, but both these processes are so absorbing that once success has been achieved it is most rare that any worker deserts them for other processes, and if this article is the means of helping any fellow-pictorialist, it will have served its purpose and fulfilled the intention of the writer.

CHRIS. J. SYMES.

DEATH OF MR. JOHN TERRAS.

WE regret to record the death, in his seventy-ninth year, of Mr. John Terras, who for sixty years has followed the profession of portrait photographer, and for a large part of that period had been the head of the business in Markinch, Fife. Mr. Terras, who was a friend of Valentine Blanchard's, began photography at a time



The late Mr. John Terras.

when his mechanical ingenuity found a useful application in the construction of his own apparatus. Throughout his business career he was constantly at work on the improvement of technical processes, and a tribute to his personal skill exists in the twenty-seven awards made to his work. He was also a most enthusiastic botanist and closely familiar with the plant life of the Lomond Hills. During the period of the war he continued his business, despite his advanced age, whilst his two sons, James and Peter, were in the R.A.F. It was, no doubt, the pressure of these circumstances which broke down his health. He is survived by his widow and two sons, to whom sympathy will be extended in their bereavement. The business will be carried on as hitherto by his sons.

FORTHCOMING EXHIBITIONS.

December 9 to 31.—Rochdale Amateur Photographic Society. Particulars from the Hon. Secretary, W. Lord, 10, Derwent Street, Rochdale.

1923.

February 5 to March 3.—Northern Photographic Exhibition, City Art Gallery, Manchester. Latest date for entries, January 12. Particulars from the Hon. Exhibition Secretary, Walter Johnson, 30, Hartington Road, Chorlton-cum-Hardy, Manchester.

February 10 to 24.—Scottish Photographic Salon. Particulars from the Secretary, George A. Ross, Northfield Cottage, Brechin.

March 1 to 8.—Birmingham Photographic Society. Latest date for entries, February 15. Particulars from the Hon. Secretary. J. E. Breeze, 178, Broad Street, Birmingham.

March 2 to 31.—Pittsburgh Salon of Photography. Latest date, February 5. Secretary, Charles K. Archer, 1,412 Carnegie Building, Pittsburgh, Pa., U.S.A.

March 13 to 16.—Exeter and West of England Photographic Exhibition. Particulars from the Hon. Secretary, R. W. J. Norton, 4, Buddle Park, St. Thomas, Exeter.

March 15 to 24.—Photographic Fair, Holland Park Hall. Secretary, Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications November 20 to 25:—

PLATE HOLDERS.—No. 31,778. Photographic plate and film holders. R. C. Matson.

COMPOSITE PHOTOGRAPH.—No. 31,825. Production or exhibition of composite photographs. A. Bennett, Move-o-graphs, Ltd., and A. E. Walsham.

APPARATUS.—No. 32,200. Machine for printing positive films. A. L. V. C. Debrie.

CINEMATOGRAPHY.—No. 32,142. Manufacture of announcement slides for cinemas, etc. J. W. C. Basnett.

CINEMATOGRAPHY. — No. 31,774. Treating cinematographic films. Pathé Cinema, Anciens Etablissements, Pathé Frères.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

HARDENED GELATINE PRINTING SURFACES.—No. 187,638 (April 18, 1921).—The invention describes the production and use of a transfer printing plate, which can be employed either for the dye or ink contact transfer process, and is applicable to monochromatic, polychromatic or natural-colour photography, both in "still" and motion picture photography. The term "colour" is intended to include "black," which sometimes technically is designated as an absence of colour.

A printing surface prepared according to the invention when treated with a dye, ink, or other colouring matter, will absorb or take up the colouring matter within a few seconds, thus differing from dye processes, among other reasons, for the fact that these require about six minutes for the absorption of the dye. When thus treated and placed in contact with a substance which is to carry the final reproduction, such as a gelatine surface, it will give up its colouring matter practically instantaneously and produce an exact and perfect reproduction. Although the saving of time and the superior results obtainable in still photography are important, this speedy result is of prime importance in the production of motion pictures, as the diffusion of dye or colour is imperceptible even when the picture is enlarged twenty-five diameters

The invention describes a method of forming a transfer printing plate by hardening parts of a photographic positive, according to the extent that they have been acted on by light, by a hardening agent and a controlling agent. The invention also consists in one form of the above method in which the positive is undeveloped before hardening, the hardening being effected during development. In another form the positive is developed before hardening, the developed positive being converted into an appropriately surfaced printing plate by potassium bichromate and sulphuric acid. The invention also consists in a modified process in which the positive printing record is formed directly from the negative on the same plate by partial development followed by exposure to light and further development. By way of example a positive is prepared from the desired negative by means of a sensitive emulsion such as a silver salt emulsion, which is exposed to the action of light through a negative. The silver salt emulsion may be carried or mounted on any desired support, either opaque, translucent, or transparent, but preferably is mounted on a transparent carrier such as glass or a cellulose base, in order that the silver salt emulsion may be exposed through its transparent carrier.

The exposed emulsion is treated by a developing solution containing a hardening or tanning agent, which renders insoluble the exposed parts of the emulsion. The unhardened or soluble portions may be removed by melting with warm water. In some kinds of reproduction the soluble portions will be removed, and in other kinds of reproduction the soluble portions will not be removed. Dyes and inks generally require different treatment. In all cases, however, the print is made from the selectively hardened parts of a positive printing surface. A sample formula for a developing solution for an emulsion exposed through its transparent carrier and containing a hardening or tanning agent is as follows:—

Water	8½ ozs.
Pyrogallic acid	11 grs.
Metol	9 grs.
Potassium bromide	4 grs.
Sodium carbonate	200 grs.
Sodium sulphite	40 to 60 grs.

In the above formula the hardening or tanning agent is pyrogallic acid, and the controlling and limiting agent is sodium sulphite. Potassium bromide also has a certain controlling and limiting effect. The main difference between the above formula and standard developing formulæ is in the amount of sodium sulphite used. In standard formulæ the amount of sodium sulphite is greatly in excess of the amount used in the above formula, and the tanning or hardening effect of the pyrogallic acid is entirely neutralised or overcome. In the given formula the sodium sulphite controlls and limits the hardening effect of the pyrogallol. The unhardened portions may then be removed if desired by placing the emulsion in warm water, which causes the unhardened or soluble portions to soften and melt away, so that the hardened emulsion alone will remain in the form of extremely minute, individual protuberances which are distributed and grouped irregularly so as to represent the photographic light and shade. When an emulsion is exposed through its transparent carrier, however, certain difficulties are encountered, unless the printing surface is very thin and lies adjacent the transparent carrier. As an ordinary commercial sensitive emulsion usually is in excess of one-thousandth of an inch in thickness, it is evident that it is likely to be penetrated deeply by the light to which it is exposed, particularly in the shadows. The resultant printing surface after treatment will have a ton thick printing surface in those portions which have been thus deeply penetrated. It is very difficult to get the darker portions of a negative recorded properly without having the lighter portions of a negative too heavy. In order to overcome these disadvantages, it was discovered that excellent results may be obtained by using an emulsion coloured with a colour which is complementary to the exposure light. When applied to photographic printing from a negative the colour will be complementary to the printing light, which generally is obtained from an incandescent electric lamp giving out blue rays. Naphthol yellow or its colour equivalent, in an aqueous solution, ten gms. of naphthol yellow to one ounce of water, will give satisfactory results. Excellent results may also be obtained by the use of a printing light complementary in colour to the natural colour of the sensitive emulsion, which may be described as of a slightly yellowish green. Such a light can be found in the highest visible violet rays of the spectrum. An arc lamp using blue flame carbons, or a mercury vapour lamp, will give satis-

New Materials.

CORRUGATED REFLECTORS.—The Westminster Engineering Co., Ltd., Victoria Road, Willesden Junction, London, N.W.10, send us a sample of a new corrugated reflecting material of their manufacture, which is giving much satisfaction in cinematograph film studios. The material has the appearance of ordinary corrugated wrapping-paper, covered on its surface by a highly-polished metallic coating. Thus the reflecting material is very flexible, and may be bent into any shape or fitted in any position. It is certainly of high reflecting power, and, from the small sample we have before us, we should say gives a softened reflection owing to the many corrugations of its surface. The material has been tested by several well-known portrait photographers in the studio, who report that it is very satisfactory as a powerful yet diffusing reflector of day or artificial light. As a reflector for half-watt lamps it should prove very useful, and being flexible could be easily fixed to any type of studio lamp fitting. The material is supplied in rolls 44 inches wide, but can be used wider than this if necessary, as it may be mounted upon wooden frames and a join made. In this manner reflecting surfaces of any dimensions are possible, and may be shaped to suit the conditions under which they are to be used. Prices are obtainable from the Westminster Engineering Co., who will be pleased to send a small sample of the material to any bona-fide professional photographer.

COLOUR PRINTS FOR PHOTOGRAPHERS.—There is no doubt that particularly at the Christmas season many photographers could do business in attractive colour prints, such as are largely sold by stationers, and at the print shops proper. Messrs. John Harrap & Son, 3, Holborn Buildings, Holborn Bars, London, E.C.1, send us some specimens of the prints which they supply for this class of business. They are of attractive landscape, seascape, and other subjects, to retail at 2s. each, and subject to a very liberal discount. Messrs. Harrap are just now making a special offer of 20 copies, all of different subjects, at the price of 21s., carriage paid, by way of inducement to photographers to test the profitable results, which follow the display of goods of this description to their regular customers.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SUNDAY, DECEMBER 10.

United Stereoscopic Society. "Architectural Photography." A. H. Page.

MONDAY, DECEMBER 11.

Bradford Phot. Soc. "A Naturalist in Holland." G. A. Booth.
City of London and Cripplegate P.S. "Lantern Slide Making." A. H. Redman.
Dewsbury P.S. "Candlelight Photography." H. A. Parkinson.
Glasgow and West of Scotland A.P. Assoc. Autochrome and Print Show.
Kidderminster and District P.S. "A.P. and P." Prize Slides.
Kinning Park Co-op. Soc. Camera Club. Lantern Slide Making.
Southampton C.C. "Winchelsea and Rye." Algernon Brooker.
Wallasey Amateur P.S. "Ensign Popular Cameras." Messrs. Houghtons, Ltd.
Walsall Phot. Soc. "My Holiday Rambles, and a Chat on Old Inns." F. S. Ellis.
Willesden Phot Soc. "The Way of the Lovely Sky." Capt. A. G. Buckham.

TUESDAY, DECEMBER 12.

Royal Photographic Society. 1. "Description of the 'N.S.' Kinematograph Camera." A. S. Newman. 2. "The Factors which Determine Gamma Infinity." G. I. Higson and F. C. Toy.
Birmingham Phot. Soc. "Psychic Photography." Fred Barlow.

FRIDAY, DECEMBER 15.

Royal Photographic Society. Discussion: Panchromatics.
Wakefield Phot. Soc. "Principles of Pictorial Photography." Fred Thorne.

SATURDAY, DECEMBER 16.

Partick Camera Club. Whist Drive.

ROYAL PHOTOGRAPHIC SOCIETY.

At the meeting held on December 1 last a paper by Mr. L. E. Banfield, on "Summer Photography in India," was read by his brother, Mr. A. C. Banfield. The author, who has lived in India for many years, dwelt upon the many difficulties of practising photography in a country where often the shade temperature is well over 100. He had a well-fitted dark-room, measuring 12 by 8 ft. and 10 ft. high, but its one drawback was its temperature, which very frequently was 104 F. The town supply of tap water was available only for two hours, morning and evening, and in midsummer would have a temperature of 110 F. when first turned on, falling, perhaps, after a little while to about 80. Therefore, water had to be previously cooled by storing it in a few of the 10-gallon earthenware porous jars, known as "mutkas." The drawback to this method of cooling water was that mosquitos in countless thousands clung to the sides of the jars, and would begin their operations as soon as the photographer shut the dark-room door. Application to the body of an essential oil, such as citron, spike or lavender, would give respite for a time, but even this measure was not the only one which had to be taken before work could be begun. It was necessary to make sure that the room was free from snakes. Scorpions were such frequent visitors that Mr. Banfield kept a piece of plank specially at hand for flattening them.

For getting the developing and other solutions to a working temperature a large bath full of water was cooled with ice, and all the tanks of solution, including the fixing tank, kept in this cooled water. After developing and fixing, films were treated in 10 per cent. formaline solution for 20 minutes, after which, for washing, they might be risked in the tap water, if it happened to be running.

Drying the films presented equally serious difficulties, owing to the eating of the gelatine by little fish ants, which ploughed a way across the wet film, like skiers on snow.

Mr. Banfield strongly urged that the difficulties of photo-

graphers in the Indian summer should be more thoroughly considered than they had been. The requirement was some hardening agent which could be applied to the films before development. Hardening after development was almost useless, because the temperature of the dark-room might be anything up to 120 deg. F., and the moment the cage of film was lifted from the developer the hot air of the room began to exert its fatal effects, so that if there was the delay of a second or two in transferring the film into the next solution, the emulsion might run into a mass of jelly. Mr. Banfield had tried every hardening agent, without finding one which gave him satisfaction. Despite these difficulties, there was an enormous attraction in using a camera among the innumerable scenes of Indian town and landscape, but civilisation was changing the customs and costumes of Indian natives, and, therefore, the need for pictorial records, particularly of figure studies, deserved to be strongly emphasised before the opportunity for making them had passed.

The paper aroused an active discussion, in which Messrs. W. B. Ferguson, N. E. Luboshey, and T. H. B. Scott took part. A hearty vote of thanks was accorded to the author and reader of the paper.

Meeting held Tuesday, December 5, under the control of the Pictorial Group, the president, Mr. W. L. F. Wastell, in the chair.

Mr. C. Lewis Hind delivered a lecture, entitled, "The Lesson of Photography," before a large and distinguished audience. Mr. Lewis Hind said he spoke, not as a photographer, because he had never taken a photograph, but as a lover of art in all its forms. The painter's point of view often made him angry, and the advice of some painter friends to "rub it in" to the photographers at this meeting did not find favour in the lecturer's mind. The so-called feud, which was at one time assumed to exist between photographers and painters, was now quite a myth, said the lecturer, as the true artist, whatever his medium may be, was the man who reproduced the essential and repelled the unessential. The often debated point, "Is photography an art?" depends entirely upon the man. Photographers may be artists every bit as much as the painter, while all painters were not artists. It had also been argued that the so-called faking or improving of negatives should not be encouraged, but this, said the lecturer, was nonsense. It did not matter what means the worker used so long as the result justified those means, and any tricks may be adopted providing the effect was obtained. Turner once used the soot from a chimney-back to produce an effect in one of his works, said Mr. Hind, and so, to-day, painters use mixtures of pigments and mediums to produce the desired result. The lesson of photography was explained by the lecturer in the fact that as photographers go on, the more and more will they annex representation, while the more painters go on the less will they annex representation.

The field of representation will, in future, be held by the camera, which can portray the true representation of a subject far better than the painter. Referring to the prints upon the exhibition walls in the room (architectural studies by Mr. Fredk. H. Evans), the lecturer said no painter would give results such as these. The painter would give his own view, while the photographer renders the view as it really is, and as other people may see it. Genius, said the lecturer, was above the rules of which he spoke, and could not be considered in an argument of this kind. Speaking of the reproduction of carving by photography or by the painter, Mr. Lewis Hind said the sculptor would prefer the work of the camera, for here he would have true representation, and not the addition of other personalities. The old masters of painting would be impressed by present-day photography, every bit as much as present-day photography was influenced by the old masters, and was now copying their vision. The lecturer then referred at some length to the work of Alfred Stieglitz, who, he said, was a camera artist of the highest degree. The whole future of true reproduction was in the hands of photography, said Mr. Hind; colour-photography and the cinema, showing how science was advancing, while the wonderful photographs of sports, shown from time to time in the papers, were types of representation which the painter had never achieved.

In the discussion which followed, Mr. Child Bayley said he was pleased to hear the lecturer mention Mr. Alfred Stieglitz, a worker whose art would some day be truly appreciated. Upon the proposition of Mr. J. Dudley Johnston, a hearty vote of thanks was accorded the lecturer for his able discourse.

At the conclusion of the lecture two exhibitions of photographs were declared open. Mr. F. C. Tilney, in referring to the work of Dr. White, in the ground floor exhibition room, said this was a collection of prints made by this eminent worker when he was about 24 years of age, or between the years 1855-1857.

Mr. F. H. Evans then made a few remarks in reference to his pictures of Westminster Abbey, and the meeting ended by the showing of a number of excellent lantern slides upon the screen.

CROYDON CAMERA CLUB.

The announcement in the syllabus that Mr. J. M. Sellors would lecture on "The Negative and the Bromide Paper: Common-sense Applied to Exposure," ill-prepared his audience for the large amount of organised common-sense it had to absorb last week. The previous week members had experienced a fair dose at the hands of Mr. C. M. Thomas, but this was soothing syrup compared to the administrations of the redoubtable honorary secretary, who must have been busy preparing his lecture for months past.

In addition to making lantern-slides, much apparatus, and tests of scales of gradation of over 100 varieties of bromide papers, four dozen beautifully made slide-rules, with two moveable scales, were designed, constructed, and distributed. They involved 48 bromide enlargements; the cutting up of 400 pieces of cardboard dead true; dry mounting on face-plates; and assembling and fitting. Stupendous!

By its aid in conjunction with such every-day appliances as a calibrated wedge of H. and D. densities, and a Sanger-Shepherd density meter, the labour of making trial exposures on a slip of bromide paper, with its attendant anxieties and uncertainty as to the best exposure, either for contact prints, or enlargements and reductions is entirely eliminated. Owing to a virulent excess of material, the slide-rule was never reached, and by request its consideration was postponed to a vacant date at Christmas, when it should add materially to the festivity of the season. Having regard to this, much matter considered by him can be more conveniently dealt with then.

He started by referring to a somewhat similar system of exposure demonstrated over nine years ago, and he inquired whether any had adopted it, but obtained no answer in the affirmative, his audience now looking distinctly uneasy. "It is evident all intelligent members have since left the club," he bitterly commented, following with a suggestion that his proposed lecture should be abandoned in favour of ping-pong. The implements of the game not being on the premises, he was asked to get on.

Proceeding, he said that in his opinion scientists were well-meaning, and if they presented things in revolting fashion, in this respect they were no worse than medical men. It was a great mistake for the practical man to ignore scientists, for after all, they were fellow-creatures and displayed remarkable intelligence at times. Messrs. Hurter and Driffield were amateurs like themselves (no uncomplimentary inference intended) who set out to evolve order out of chaos, and were remarkably fitted for the job.

Next came a really luminous exposition of shadow, prism, and grease-spot photometers, all simple instruments, yet capable of accurate work. This was followed by an equally clear description of the calibrated wedge. Hopelessly behind time at this stage, a number of diagrams received far too brief attention. He finally wound up with a grievance against some manufacturers of bromide-paper, who inserted it in envelopes, apparently with a special machine guaranteed to prevent withdrawal without damage. The system adopted by the Kodak Company was, however, excellent.

In the discussion, Mr. H. P. C. Harpur said he was possessed of a fair vocabulary, but no words could express what he thought about the system advocated. Turning to the infinite, he portentiously added that the lecture, instead of awakening in him a wish to know more, had induced a strong desire to know considerably less. On the other hand, much appreciation for a lecture of unusual interest, one which must have involved an enormous amount of work, was expressed by many. Mr. J. W. Purkis said it was the finest scientific lecture on popular lines he had ever heard, and was an object lesson in showing that really useful research work could be done with simple apparatus. The lecturer had also interpretated in a very plain way the "shorthand" so largely used by scientists, and little understood by the general run of photographers.

ANGLO-HIBERNIAN TRADING CO., LTD.—Since the particulars given on page 730 in our issue of December 1 last were filed, the registered office of the company has been transferred, so we are informed, to 6, Great Arthur Street, Goswell Road, London, E.C.1.

New Materials.

Corrugated Reflectors. — The Westminster Engineering Co., Ltd., Victoria Road, Willesden Junction, London, N.W.10, send us a sample of a new corrugated reflecting material of their manufacture, which is giving much satisfaction in cinematograph film studios. The material has the appearance of ordinary corrugated wrapping-paper, covered on its surface by a highly-polished metallic coating. Thus the reflecting material is very flexible, and may be bent into any shape or fitted in any position. It is certainly of high reflecting power, and, from the small sample we have before us, we should say gives a softened reflection owing to the many corrugations of its surface. The material has been tested by several well-known portrait photographers in the studio, who report that it is very satisfactory as a powerful yet diffusing reflector of day or artificial light. As a reflector for half-watt lamps it should prove very useful, and being flexible could be easily fixed to any type of studio lamp fitting. The material is supplied in rolls 44 inches wide, but can be used wider than this if necessary, as it may be mounted upon wooden frames and a join made. In this manner reflecting surfaces of any dimensions are possible, and may be shaped to suit the conditions under which they are to be used. Prices are obtainable from the Westminster Engineering Co., who will be pleased to send a small sample of the material to any bona-fide professional photographer.

Colour Prints for Photographers.—There is no doubt that particularly at the Christmas season many photographers could do business in attractive colour prints, such as are largely sold by stationers, and at the print shops proper. Messrs. John Harrap & Son, 3, Holborn Buildings, Holborn Bars, London, E.C.1, send us some specimens of the prints which they supply for this class of business. They are of attractive landscape, seascape, and other subjects, to retail at 2s. each, and subject to a very liberal discount. Messrs. Harrap are just now making a special offer of 20 copies, all of different subjects, at the price of 21s., carriage paid, by way of inducement to photographers to test the profitable results, which follow the display of goods of this description to their regular customers.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Sunday, December 10.

United Stereoscopic Society. "Architectural Photography." A. H. Page.

Monday, December 11.

Bradford Phot. Soc. "A Naturalist in Holland." G. A. Booth.
City of London and Cripplegate P.S. "Lantern Slide Making." A. H. Redman.
Dewsbury P.S. "Candlelight Photography." H. A. Parkinson.
Glasgow and West of Scotland A.P. Assoc. Autochrome and Print Show.
Kidderminster and District P.S. "A.P. and P." Prize Slides.
Kinning Park Co-op. Soc. Camera Club. Lantern Slide Making.
Southampton C.C. "Winchelsea and Rye." Algernon Brooker.
Wallasey Amateur P.S. "Ensign Popular Cameras." Messrs. Houghtons, Ltd.
Walsall Phot. Soc. "My Holiday Rambles, and a Chat on Old Inns." F. S. Ellis.
Willesden Phot Soc. "The Way of the Lovely Sky." Capt. A. G. Buckham.

Tuesday, December 12.

Royal Photographic Society. 1. "Description of the 'N.S.' Kinematograph Camera." A. S. Newman. 2. "The Factors which Determine Gamma Infinity." G. I. Higson and F. C. Toy.
Birmingham Phot. Soc. "Psychic Photography." Fred Barlow.
Bournemouth Camera Club. Lantern Slide Competition.
Cambridge and District Phot. Club. "Head Hunters of Borneo." Dr. A. C. Haddon.
Exeter Camera Club. Exhibition of 1921 R.P.S. Affiliation Competition Prints.

Saturday, December 16.

Partick Camera Club. Whist Drive.

ROYAL PHOTOGRAPHIC SOCIETY.

At the meeting held on December 1 last a paper by Mr. L. E. Banfield, on "Summer Photography in India," was read by his brother, Mr. A. C. Banfield. The author, who has lived in India for many years, dwelt upon the many difficulties of practising photography in a country where often the shade temperature is well over 100. He had a well-fitted dark-room, measuring 12 by 8 ft. and 10 ft. high, but its one drawback was its temperature, which very frequently was 104 F. The town supply of tap water was available only for two hours, morning and evening, and in midsummer would have a temperature of 110 F. when first turned on, falling, perhaps, after a little while to about 80. Therefore, water had to be previously cooled by storing it in a few of the 10-gallon earthenware porous jars, known as "mutkas." The drawback to this method of cooling water was that mosquitos in countless thousands clung to the sides of the jars, and would begin their operations as soon as the photographer shut the dark-room door. Application to the body of an essential oil, such as citron, spike or lavender, would give respite for a time, but even this measure was not the only one which had to be taken before work could be begun. It was necessary to make sure that the room was free from snakes. Scorpions were such frequent visitors that Mr. Banfield kept a piece of plank specially at hand for flattening them.

For getting the developing and other solutions to a working temperature a large bath full of water was cooled with ice, and all the tanks of solution, including the fixing tank, kept in this cooled water. After developing and fixing, films were treated in 10 per cent. formaline solution for 20 minutes, after which, for washing, they might be risked in the tap water, if it happened to be running.

Drying the films presented equally serious difficulties, owing to the eating of the gelatine by little fish ants, which ploughed a way across the wet film, like skiers on snow.

Mr. Banfield strongly urged that the difficulties of photo-

graphers in the Indian summer should be more thoroughly considered than they had been. The requirement was some hardening agent which could be applied to the films before development. Hardening after development was almost useless, because the temperature of the dark-room might be anything up to 120 deg. F., and the moment the cage of film was lifted from the developer the hot air of the room began to exert its fatal effects, so that if there was the delay of a second or two in transferring the film into the next solution, the emulsion might run into a mass of jelly. Mr. Banfield had tried every hardening agent, without finding one which gave him satisfaction. Despite these difficulties, there was an enormous attraction in using a camera among the innumerable scenes of Indian town and landscape, but civilisation was changing the customs and costumes of Indian natives, and, therefore, the need for pictorial records, particularly of figure studies, deserved to be strongly emphasised before the opportunity for making them had passed.

The paper aroused an active discussion, in which Messrs. W. B. Ferguson, N. E. Luboshey, and T. H. B. Scott took part. A hearty vote of thanks was accorded to the author and reader of the paper.

Meeting held Tuesday, December 5, under the control of the Pictorial Group, the president, Mr. W. L. F. Wastell, in the chair.

Mr. C. Lewis Hind delivered a lecture, entitled, "The Lesson of Photography," before a large and distinguished audience. Mr. Lewis Hind said he spoke, not as a photographer, because he had never taken a photograph, but as a lover of art in all its forms. The painter's point of view often made him angry, and the advice of some painter friends to "rub it in" to the photographers at this meeting did not find favour in the lecturer's mind. The so-called feud, which was at one time assumed to exist between photographers and painters, was now quite a myth, said the lecturer, as the true artist, whatever his medium may be, was the man who reproduced the essential and repelled the unessential. The often debated point, "Is photography an art?" depends entirely upon the man. Photographers may be artists every bit as much as the painter, while all painters were not artists. It had also been argued that the so-called faking or improving of negatives should not be encouraged, but this, said the lecturer, was nonsense. It did not matter what means the worker used so long as the result justified those means, and any tricks may be adopted providing the effect was obtained. Turner once used the soot from a chimney-back to produce an effect in one of his works, said Mr. Hind, and so, to-day, painters use mixtures of pigments and mediums to produce the desired result. The lesson of photography was explained by the lecturer in the fact that as photographers go on, the more and more will they annex representation, while the more painters go on the less will they annex representation.

The field of representation will, in future, be held by the camera, which can portray the true representation of a subject far better than the painter. Referring to the prints upon the exhibition walls in the room (architectural studies by Mr. Fredk. H. Evans), the lecturer said no painter would give results such as these. The painter would give his own view, while the photographer renders the view as it really is, and as other people may see it. Genius, said the lecturer, was above the rules of which he spoke, and could not be considered in an argument of this kind. Speaking of the reproduction of carving by photography or by the painter, Mr. Lewis Hind said the sculptor would prefer the work of the camera, for here he would have true representation, and not the addition of other personalities. The old masters of painting would be impressed by present-day photography, every bit as much as present-day photography was influenced by the old masters, and was now copying their vision. The lecturer then referred at some length to the work of Alfred Stieglitz, who, he said, was a camera artist of the highest degree. The whole future of true reproduction was in the hands of photography, said Mr. Hind; colour-photography and the cinema, showing how science was advancing, while the wonderful photographs of sports, shown from time to time in the papers, were types of representation which the painter had never achieved.

In the discussion which followed, Mr. Child Bayley said he was pleased to hear the lecturer mention Mr. Alfred Stieglitz, a worker whose art would some day be truly appreciated. Upon the proposition of Mr. J. Dudley Johnston, a hearty vote of thanks was accorded the lecturer for his able discourse.

At the conclusion of the lecture two exhibitions of photographs were declared open. Mr. F. C. Tilney, in referring to the work of Dr. White, in the ground floor exhibition room, said this was a collection of prints made by this eminent worker when he was about 24 years of age, or between the years 1855-1857.

Mr. F. H. Evans then made a few remarks in reference to his pictures of Westminster Abbey, and the meeting ended by the showing of a number of excellent lantern slides upon the screen.

CROYDON CAMERA CLUB.

The announcement in the syllabus that Mr. J. M. Sellors would lecture on "The Negative and the Bromide Paper: Common-sense Applied to Exposure," ill-prepared his audience for the large amount of organised common-sense it had to absorb last week. The previous week members had experienced a fair dose at the hands of Mr. C. M. Thomas, but this was soothing syrup compared to the administrations of the redoubtable honorary secretary, who must have been busy preparing his lecture for months past.

In addition to making lantern-slides, much apparatus, and tests of scales of gradation of over 100 varieties of bromide papers, four dozen beautifully made slide-rules, with two moveable scales, were designed, constructed, and distributed. They involved 48 bromide enlargements; the cutting up of 400 pieces of cardboard dead true; dry mounting on face-plates; and assembling and fitting. Stupendous!

By its aid in conjunction with such every-day appliances as a calibrated wedge of H. and D. densities, and a Sanger-Shepherd density meter, the labour of making trial exposures on a slip of bromide paper, with its attendant anxieties and uncertainty as to the best exposure, either for contact prints, or enlargements and reductions is entirely eliminated. Owing to a virulent excess of material, the slide-rule was never reached, and by request its consideration was postponed to a vacant date at Christmas, when it should add materially to the festivity of the season. Having regard to this, much matter considered by him can be more conveniently dealt with then.

He started by referring to a somewhat similar system of exposure demonstrated over nine years ago, and he inquired whether any had adopted it, but obtained no answer in the affirmative, his audience now looking distinctly uneasy. "It is evident all intelligent members have since left the club," he bitterly commented, following with a suggestion that his proposed lecture should be abandoned in favour of ping-pong. The implements of the game not being on the premises, he was asked to get on.

Proceeding, he said that in his opinion scientists were well-meaning, and if they presented things in revolting fashion, in this respect they were no worse than medical men. It was a great mistake for the practical man to ignore scientists, for after all, they were fellow-creatures and displayed remarkable intelligence at times. Messrs. Hurter and Driffield were amateurs like themselves (no uncomplimentary inference intended) who set out to evolve order out of chaos, and were remarkably fitted for the job.

Next came a really luminous exposition of shadow, prism, and grease-spot photometers, all simple instruments, yet capable of accurate work. This was followed by an equally clear description of the calibrated wedge. Hopelessly behind time at this stage, a number of diagrams received far too brief attention. He finally wound up with a grievance against some manufacturers of bromide-paper, who inserted it in envelopes, apparently with a special machine guaranteed to prevent withdrawal without damage. The system adopted by the Kodak Company was, however, excellent.

In the discussion, Mr. H. P. C. Harpur said he was possessed of a fair vocabulary, but no words could express what he thought about the system advocated. Turning to the infinite, he portentiously added that the lecture, instead of awakening in him a wish to know more, had induced a strong desire to know considerably less. On the other hand, much appreciation for a lecture of unusual interest, one which must have involved an enormous amount of work, was expressed by many. Mr. J. W. Purkis said it was the finest scientific lecture on popular lines he had ever heard, and was an object lesson in showing that really useful research work could be done with simple apparatus. The lecturer had also interpretated in a very plain way the "shorthand" so largely used by scientists, and little understood by the general run of photographers.

ANGLO-HIBERNIAN TRADING CO., LTD.—Since the particulars given on page 730 in our issue of December 1 last were filed, the registered office of the company has been transferred, so we are informed, to 6, Great Arthur Street, Goswell Road, London, E.C.1.

Commercial & Legal Intelligence.

FAILURE OF A PHOTO ENLARGEMENT CO.—At the offices of the Board of Trade, Carey Street, W.C., last week, the statutory meetings of creditors and contributories were held in the matter of Spencer Enterprises, Ltd., 179, Archway Road, Highgate, N.

Mr. G. D. Pepys, Official Receiver, presided, and reported that the winding-up order was made on April 11, 1922, on a creditor's petition. No statement of affairs had yet been filed, but the late managing director, Mr. Henry Spencer, was engaged in preparing it. The company was incorporated as a private company on January 4, 1921, with a nominal capital of £3,000, subsequently increased to £5,000, to acquire and carry on business, in which Mr. Spencer had been engaged, called The Spencer Picture Framing and Portrait Enlarging Co. Mr. Spencer had signed the minute book and documents as chairman and managing director, and his wife had acted as director and secretary. On October 17, 1921, a Mr. Wm. J. McDavid was appointed secretary and director in place of Mrs. Spencer, but he resigned a month later.

The business had only been commenced a few months before the incorporation of the company, and consisted of selling painted enlargements of photographs, to be paid for on a weekly basis. The work was not done by the company, the oil paintings being prepared by certain firms of enlargers, and they were delivered to customers through the medium of various branches which were opened to obtain orders and collect payments.

The working capital seemed to have been procured from various persons who answered advertisements inserted by Mr. Spencer asking for branch managers, who were to receive £4 or £5 per week, plus a percentage of profits. Each manager was to deposit a certain amount of money, usually £200 or £250, with Mr. Spencer. This was the procedure before the incorporation of the company, and each manager received a service agreement under which his deposit or investment was returnable with interest at the end of one year, and each branch manager was given a lien on the assets of his particular branch. Up to the end of December, 1920, the records showed that about eleven managers had joined Mr. Spencer, and that about four branches had been opened. Under the sale agreement to the company, the purchase consideration was £2,000 in shares, and Mr. Spencer was relieved of all liabilities in respect of the business and indemnified against any claims which might arise thereunder.

After the incorporation of the company, Mr. Spencer, as managing director, continued to procure further managers, who paid to him sums varying from £200 to £250 each as an investment in the business of the company, and each of those managers entered into a service agreement similar to the others, but there was one important difference, namely that although each manager was given a lien on the assets of his branch by the agreement, the lien or charge was not registered as a charge on the business assets. Further branches were opened in various parts of the country, until at one time there were about 30 branches in existence, and it rather looked as if Mr. Spencer devoted his attention more to procuring a larger number of managers and their investments, than to putting the earlier branches on a paying basis. The company was short of funds throughout, and its growing expenses were only met by the fresh investments coming in from new men.

In October, 1921, 80 debentures of £25 each, secured as a floating charge on the assets of the company, were issued to Mr. McDavid, who paid to the company £200. Some three days later Mr. McDavid appeared to have become dissatisfied, and obtained the return of £1,000. The Official Receiver was of opinion that there was certain evidence that the business could have been worked economically as a one man business, but having regard to the reckless way this company had carried on, there was no prospect of success. From lists prepared by Mr. Spencer the preferential claims amounted to £1,943, debenture holder's claim £950 plus interest, unsecured creditors £12,047, making a total of £14,940, but that did not include liability to customers for enlargements for which they had already paid. The total deficiency was roughly estimated at £20,000.

The liquidation remains in the hands of the Official Receiver.

NORMANTON PHOTOGRAPHIC SOCIETY.—A new society has been formed under the above name, with Mr. W. Warburton as president. Meetings are held weekly in the Baptist Schoolroom, and persons interested are asked to communicate with the secretary, Mr. F. R. Townsend, Myrtle House, Altofts, Normanton, Yorks.

News and Notes.

THE KODAK MAGAZINE.—A monthly magazine, dealing with the attractions of Kodak amateur photography, is being issued by the Kodak Company and will be obtainable from all Kodak branches and dealers, price 2d. per issue. The first number, namely, that for January next, will be on sale on or before December 20 next. Succeeding issues will be published on the 15th of each month.

A MEETING of the Scientific and Technical Group of the Royal Photographic Society will be held on Tuesday, December 12, at 35, Russell Square, London, W.C.1, commencing at 7 p.m. Two papers will be read as follows:—"Description of the 'N.S.' Cinematograph Camera," with special reference to an electric drive, by A. S. Newman, and "The Factors Which Determine Gamma Infinity," by Messrs. G. I. Higson and F. C. Toy.

KODAK PROFESSIONAL REQUISITES.—An 8-page circular, just issued by the Kodak Company, and obtainable from them at Kodak House, Kingsway, London, W.C.2, describes and illustrates a number of recent introductions, among which are "portrait gift certificates," mask charts for trimming prints, and head screens. The booklet also gives the substantially reduced prices at which the Eastman Portrait diffusion discs are now supplied.

PHOTOGRAPHS ENHANCE A BLUE BOOK.—One does not look for interesting photographs in a Government "Blue Book," but they are used with good effect in one published by the Royal Commission on Historical Monuments. It is called "An Inventory of the Historical Monuments in Essex," Vol. II., and is issued by H.M. Stationery Office at £2. This handsome, well-bound volume is printed on fine paper, and contains over 300 pages, profusely illustrated with excellent and specially-taken photographs.

CAMERA HOUSE JOURNAL.—The Christmas gift number of Messrs. Butcher's little publication gives particulars of articles most suitable for presents at this time of the year. Prominence is given to the Primus engineering sets, while lanterns and toy cinematographs also find a place. Sample strips of the patent passepartout binding are included in the booklet, so that dealers may test this material for themselves. The Journal is obtainable by the trade only, upon application to Messrs. W. Butcher & Sons, Ltd., Camera House, Farringdon Avenue, London, E.C.4.

PHOTOGRAPHIC PORTRAITURE IN TURKEY.—The writer of the paragraph appearing under this heading on page 731 of last week's issue writes as follows: "The omission of two words in the fifth line makes this item of news read very peculiarly; the line should read 'the making of pictures of living things,' etc. The actual words of the Koranic command are 'Every painter is in danger of hell fire, and Allah will appoint a person at the day of resurrection to punish him for every picture he shall have drawn, and he shall be punished in hell. So if ye must make pictures, make them of trees and things without souls.' Happily for some of us photographers are not painters, though the true Moslem considers a photographer to be one."

ROYAL INSTITUTION LECTURES.—The Juvenile Lectures at the Royal Institution this Christmas will be delivered by Professor H. H. Turner, whose subject is "Six Steps up the Ladder to the Stars." The first lecture will be given on Thursday, December 28, on "The Distance of the Stars," followed by "The Discovery of the Planet Neptune," "Photographing the Stars," "The Spectroscope and its Revelations," "Two Great Streams of Stars," and "The Size of a Star." Among the lecture arrangements before Easter are:—On Tuesday afternoons, commencing January 16, there will be two lectures by Professor F. G. Donnan, on "Semi-Permeable Membranes and Colloid Chemistry," two by Mr. R. D. Oldham on "Earthquakes," and two by Professor C. G. Seligman on "Rainmakers and Divine Kings of the Nile Valley." On Thursday afternoons, Professor B. Melvill Jones will give two lectures on "Recent Experiments in Aerial Surveying." The first Friday evening discourse will be delivered by Sir James Dewar on January 19 on "Soap Films as Detectors of Stream Lines, Vortex Motion and Sound."

A NEW FRENCH JOURNAL.—Those who are readers of Continental photographic literature are no doubt familiar with the admirable supplement to "La Revue Française de Photographie," compiled by M. L. P. Clerc, and entitled "Science Technique et Industrie Photographiques." We learn from the current issue of our contemporary that next year this supplement is to be made a separate monthly publication, bearing the same title, under the editorship of

M. Clerc. Each issue will consist of from 32 to 40 pages of text, and will include a bibliographical review of the scientific, photographic, and cinematographic press of all countries, in addition to original articles and communications. We are quite sure that "Science Technique et Indnstries" will merit the support of all those who are interested in the advances which are being made in any country in photographic processes, materials or apparatus. The annual subscription for the new magazine will be 12 francs for places in France; 17 francs for places in the Postal Union. Applications for the new publication should be addressed to M. Paul Montel, 35, Boulevard Saint-Jacques, Paris XIVe.

Correspondence.

*** *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

*** *We do not undertake responsibility for the opinions expressed by our correspondents.*

EASILY-MADE ANNOUNCEMENT SLIDES.

To the Editors.

Gentlemen,—The December issue of the R.P.S. "Journal" has arrived containing Mr. Wastell's Presidential address on "The Evolution of the Lantern Slide."

Mention is made in the address of some transparent drawings by Della Porta over 300 years ago, drawings in which we find the prototype of the lantern slide, and the mention of these old-time lantern pictnres reminds me of a wheeze I thought ont and worked successfully during the recent general election. The process, which I mnst admit is not purely photographic, may be of service to some of yoor readers who have a lantern.

Having made photographic lantern slides of election subjects, portraits, events, etc., I was asked what I could do in the way of making announcement slides quickly and effectively. Time did not allow me to get the commercially prepared black slides for writing upon, or to make slides with matt varnish, not having the latter at hand.

What I did was to write the required announcements on ordinary writing paper using waterproof black ink; these were then dried on the hot-water pipes in the room. When dry, and still on the water pipes, the writing paper "slides" were rubbed well with the bottom end of a wax candle; the heat caused the candle to melt and saturate the paper, making it beautifully translucent, and in a condition to show well upon the screen.

The waxed paper slides were then placed between two pieces of plain glass for use in the lantern carrier. The glasses were not necessary (but advisable) when stiff paper was used, but if kept for a long time in the lantern the heat caused the unglazed slides to buckle a little and get out of focus. Glazing kept the announcements flat and in focos. Slides made in this way cost little or nothing, and they are most effective, taking but a minnte or so to make.—Yours faithfully,

A. Reeves.

LANTERN SLIDES FROM HALF-TONE ILLUSTRATIONS

To the Editors.

Gentlemen,—Some time ago there appeared in your pages hints concerning the copying of half-tone illnstrations and various methods of eliminating or minimising the "dots" were given. Hitherto when I have made lantern slide copies of half tone originals I have over exposed the copy negatives, over-developed them, and afterwards reduced in the hypo-ferricyanido reducer a plan advocated by one of your correspondents for doing away with the screen effect when the pictnre is enlarged npon the lantern screen.

A few days ago I was called upon to make some more slides for lecture purposes from half-tone originals, and I have discovered what I believe to be a better system of working, it is certainly an easier plan, and the results—if the half-tone screen is not too coarse—are very satisfactory.

The method is to make the copy negatives on the Barnet matt plates, the matt emulsion of these plates helping to eliminate the dot effect. If the slides are then made by contact from the matt-surface negatives the dots almost disappear. The matt grain of the negative film seems to prevent the film of the lantern plate coming in very close contact with the developed image, and if a soft diffused light, and not a point of light, is used for printing, very satisfactory and soft results can be secured. Imperial matt lantern plates were used for some with success.

It may be argued that if this plan of working destroys the dots it will also destroy the clearness of the outlines of the picture, and, also, that the grain of the matt emulsion is likely to interfere with the brilliancy of the high-lights as seen in the finished slide. In theory these arguments are against the process, but in practice they need not be considered, for the results are most pleasing.

I have made some very good copy negatives on the Imperial matt transparency or lantern plate. The grain of the latter is much finer and not so perceptible as that found on the Barnet plate; it is more opalescent or "milky," and capital for transparency work, it taking the pencil very well. Too brilliant spots of high-lights on these lantern plates may be pencilled down without the lead appearing grainy. Yours faithfully,

W. L. Mevnell-Thompson.

LUBRICATING ROLLER-BLIND SHUTTERS.

To the Editors.

Gentlemen,—Roller-blind shutters often stick at low speeds and with low spring tension, and it is necessary to apply some kind of lubricant. I find that powdered French chalk is an excellent substance to remedy this trouble, and if a little is applied to the bearing ends of the rollers and the shutter worked several times a great improvement will be observed. Any loose powder should be blown away, and the shutter will now be quite satisfactory.

Yours faithfully,

G. Garner.

BROMOIL AND BROMOIL TRANSFER.

To the Editors.

Gentlemen,—The article by Mr. C. J. Symes interested me, and no doubt hundreds of others, very much. I am an enthusiastic Bromoil worker and transferer. There are, however, one or two points in Mr. Symes' article that I must take exception to.

In my opinion, the strength of the fixing baths is immaterial, as also is time of fixing providing the print is thoroughly fixed. As regards temperature of solutions, this is not so important as most workers would have us believe; it is not essential that all solutions and the washing water should be at the same temperature. Quite a good Bromoil can be obtained from a bromide print that has been over-exposed and under-developed; in order to soften high lights I frequently over-expose to get a softer effect. Regarding the transfer process, I have used all the brands of papers mentioned by Mr. Symes, and the one I find most useful both for bromoil and transfer is Vitegas (20 B and 21B). Mr. Symes is quite in error in saying that Vitegas is not suitable for transfer. If either Mr. Symes or yourselves would care to see some transfers from Vitegas I shall be very glad to send some for your inspection, also transfer from an over-exposed under-developed Vitegas print. When inking up from transfer, I generally get as hard a print as possible, frequently intensifying the negative with uranium, as I find that the shadows transfer 50 per cent. of ink, and the high-lights some 90 per cent. or 95 per cent., which with a suitable Bromoil will give a flat transfer.

For transfers I invariably ink up with a roller. Now comes the only point I have against Vitegas: it will not stand very much work with a roller, as the base splits and comes up in blisters, which, if large, show in the transfer as a dark line; if small, they will not trouble you.

Still I prefer Vitegas, and my method of working is to get a hard print and use ink thinned down so that the suction caused by the roller is not sufficient to split the base. If Messrs. Kosmos, Ltd., would make a Bromoil paper on a base that did not split under the action of a gelatine roller, they would have an ideal Bromoil paper. A whole plate print that has been bleached and dried a month or more can be inked up after not more than ten minutes soaking in cold water. I prefer an amidol developer, very much diluted.

When requiring an unusually hard Bromoil for transfer I frequently fix in an acid hardening fixing bath, soak in very hot water for ten minutes, and finish soaking in cold water. I prefer

to dry prints both after fixing and after bleaching, etc. I find a one-solution copper sulphate bleacher quite the best.

When a very large print is to be inked, and trouble from drying is anticipated, the bleached print can be kept in working order by finishing up the final soaking by ten minutes in a 40 per cent. or 50 per cent. glycerine solution, which keeps the print damp for days. More care is required in blotting off after a glycerine bath.

I have frequently mounted a Bromoil on Vitegas less than four hours after inking up. I am not connected in any way with, nor have any interest in, the makers of Vitegas.—Yours faithfully,

H. KENWAY.

Hagley, Gt. Ormes Road. Llandudno, December 2.

THE P.P.A. CONGRESS.

To the Editors.

Gentlemen,—By report in "B.J." I see it is proposed to hold an "abbreviated" congress in March. If there are to be no demonstrations, lectures, or exhibition, it will attract very few, and then it will be said that the Spring Congress was a failure, as compared with the Autumn.

If a full programme cannot be arranged, it will be better to postpone it. The date should never have been altered, as the Spring Congress was always a success.—Yours faithfully,

"COUNTRY PRO."

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

DISHES.—The firm for large size, deep, enamelled steel dishes is Messrs. O. Sichel & Samuelson, 52, Bunhill Row, London, E.C.1.

W. B. C.—The firms for readings for lantern slides are Messrs. Newton and Co., 37, King Street, Covent Garden, London, W.C.2, and Messrs. York and Sons, 3, Emperor's Gate, South Kensington. London, S.W.7.

E. B.—Your arrangement as sketched should work very well, but it would, we think, be better to keep the three lamps more to one side of the sitter, as in your plan the lighting would be very flat. We prefer clear lamps with the thinnest possible nainsook for diffusion. Japanese silk, if thick enough, would answer well, but it has a tendency to turn yellow when washed.

F. B.—Two books which should suit you are:—"The Handbook of Cinematography, by Colin Bennett, published by Messrs. E. T. Heron and Co., 9, Tottenham Street, London, W.1., price 5s. 6d. post free, and "Practical Color Photography," by E. J. Wall, obtainable from our publishers, Messrs. Henry Greenwood and Co., Ltd., 24, Wellington Street, London, W.C.2, price 13s. 3d. post free.

P. S. S.—Ether, benzene (not benzole), or petrol would remove the linseed oil stains. The best method would be to place a piece of clean blotting paper over the stained spot and to pour a small quantity of the solvent upon this. Gentle pressure combined with warmth of the fingers will help the removal. Care should be taken that no open flame is near when the work is being done.

E. M. S.—"Commercial Photography" deals to the extent of 4 or 5 pages with engineering subjects, though it does not touch specifically upon the making of phantom views. These are usually done by coating the glass side of the negative with a matt varnish (which may be slightly tinted) and scraping away the parts which represent the foreground part of the subject. The background is thus caused to print faint.

S. W.—The copyright in the photographs is the property of the photographer who originally gave the complimentary sitting. You will be infringing that copyright by copying the prints to your customer's order. The fact that she has subsequently purchased and paid for portraits from the original negatives does not affect the matter. The owner of the copyright is naturally quite entitled to sell prints from the negatives to anyone he likes.

A. Y.—Unless you specifically undertook to make the negatives for delivery to your customer, or unless you have worded your invoices so that it might be reasonably supposed that you meant the negatives to be the customer's property, the customer has no right whatever to the negatives. This question has been decided on several occasions in the Law Courts, and is dealt with at length in the little manual which we publish, "Photographic Copyright." If you are going to charge for the negatives, a price which has been recommended by the P.P.A. is that of from 10s. 6d. to 15s. each.

S. F.—No trouble should be experienced in developing the plates which have been exposed 10 years if a pyro soda developer is used diluted with an equal volume of water and to which 10 per cent. potassium bromide solution is added in the proportion of 1 minim to each ounce of mixed developer. You will probably get dark edges in your negatives owing to the age of the plates, but if the exposures were correct, or nearly so, and the plates have been carefully stored, you should get quite good negatives. If the diluted developer is found to be working too slowly, remove the plates and place them in a correct strength developer.

J. R.—We are afraid that the regular apprenticeship system has gone by the board of late years, and the conditions under which the present day master photographers were apprenticed no longer apply. We do not think there is any usual custom as regards term of years or remuneration of the apprentices. Some people get £50 premium and pay the apprentice next to nothing, while others get little or no premium and pay the apprentice 10s. a week and upwards. We rather have the idea that the P.P.A., of which no doubt you are a member, has a model form of terms of apprenticeship which they supply for the information of their members.

E. M.—We should say it would be quite impossible to get good negatives of children in school at the present time of year using only daylight. Even with a lens at *f*/4.5 aperture and rapid plates and in an extremely well-lighted class room exposures of 10 to 20 seconds would be necessary, which would be far too long to arrest movement. We fail to see why you should not use flashlight. If after focussing you draw the blinds and stop down your lens to about *f*/11 you will be able to get results without any sign of movement. Also the present-day flash powders, such as Johnson's "Professional" powder, give little or no smoke, and children generally like the flash. We have in the past done a large amount of work of this kind, and have found the flashlight method very efficient. If you decide to work by flashlight we should recommend you to obtain a good class R.R. lens of fairly wide angle and work in half-plate size.

JOURNAL OF PHOTOGRAPHY.

No. 3267. Vol. LXIX. FRIDAY, DECEMBER 15, 1922. Price Fourpence.

Contents.

SUMMARY.

While flashlight for commercial portraiture is scarcely considered in this country, it obtains widespread use in the United States, largely as the outcome of the supply of complete apparatus which encloses the smoke of the flash and is of ample power. We refer to the design of such studio flash cabinets in a leading article on page 750.

The current talk by Mr. J. Effel on studio portraiture deals further with the posing of hands and feet in full-length figures and gives some good advice on the things to be looked for in avoiding the stiffness of many full-length masculine portraits. (P. 751.)

Messrs. Elliott & Fry have signalised the opening of their new premises in Baker Street by holding an exhibition of portraits of eminent Victorians chosen from the work done by them during the past sixty years. (P. 758.)

A rear attachment for conversion of an ordinary field camera into one allowing of the outdoor making of while you wait ferrotype portraits is described and illustrated in a contributed article by Mr. C. J. Sims. (P. 754.)

Variety in portraiture may often be obtained by taking advantage of places, e.g., the reception room, other than the studio. (P. 750.)

In an article in "American Photography" Mr. H. G. Cleveland gives a new formula for the phenosafranine desensitiser, which facilitates the illumination of residual stain of the dye, and also confers better keeping qualities upon the desensitising bath. (P. 753.)

Mr. A. C. Banfield has described the advantageous revolution of his own dark room by the adoption of desensitising as regular practice in dealing with the development of large numbers of plates. (P. 755.)

Mr. F. C. Tilney has discovered an "Old Master" in photography John Forbes White, and has brought together at the R.P.S. an exhibition of his work, which he reviews on page 757.

The wonderfully realistic architectural photography of Mr. Frederick H. Evans is also being shown at Russell Square, together with the colour pastel prints of Dr. D'Arcy Power, which were shown some time ago at the Croydon Camera Club. (P. 757.)

Improvising dark rooms and the photography of appliances fitted within the fuselage of aeroplanes are among the subjects of "Assistants' Notes." (P. 756.)

Slowness in inking and heavy "hopping" with a hard brush are two causes which lead to failure in obtaining good impressions in the Bromoil transfer process. (P. 750.)

A great deal can be done to keep the dark room floor dry and free from chemical dust by the design of working benches, even in circumstances where the use of sinks of ample size is not practicable. (P. 749.)

We refer once again to the reduction of retouching which follows from the use of panchromatic plates for freckled or fair sitters. (P. 749.)

One or two hints on the use of backgrounds are given in a paragraph on page 750.

EX CATHEDRA.

Panchromatic Portraiture. Now that tank development has become a commonplace of the studio, and the last difficulty in the way of using panchromatic plates has thus been removed, it may be worth while to point out the great advantage of using panchromatic plates in conjunction with half-watt lamps upon sitters who, from freckles or other unequal colouring of the skin, provide too much work for the retoucher. It is only by a careful test between an ordinary or even an orthochromatic plate and a panchromatic that the extent of the improvement can be realised. It has been found that under similar conditions the lighting appears softer in a panchromatic negative than in an ordinary one. With very deep yellow hair, especially if conjoined with blue drapery, a pale yellow filter may be used with advantage, but care must be taken not to overdo the correction, or the result will appear somewhat insipid. If too dark a filter be used, deep golden hair will appear as if flaxen, which is wrong. The multiplying factor of the filter, it should be noted, is much smaller with panchromatic than with orthochromatic plates.

* *

The Dark-room Floor. Visiting several dark rooms lately we have been struck by the apologies offered to us by their owners as to the wet state of the floor. The trouble usually occurs from the fact that benches are used for the various developing and washing operations, and any liquid which is spilled naturally runs to the floor. Apart from the general discomfort is the danger of these solutions drying and allowing the crystals of chemicals which they once contained to be blown about and ultimately deposit themselves upon everything in the room. If it is impossible to have a large enough sink to take all dishes and washing apparatus, it will be found of great use if the benches are covered with thin sheet lead. To do this effectively a rail of wood, one inch square, should be placed round the edge of the bench top to convert this into a kind of large dish, and the sheet lead hammered over this. The bench should be given a slight tilt to one end, so that all solutions spilt from the dishes will run towards one end. At this end a slot should be cut in the wooden rim and the lead bent down to form a spout. If the bench is over a drain the liquid may be made to run into this, but if the drain is some distance away, a funnel, to which is attached a sufficiently long piece of rubber tubing, may be utilised to carry the spillings to the proper place. The floor should be covered with lattice boards, made by nailing strips of rough battening about 2½ inches wide, to each other, crossing at right angles. It is also necessary to keep all utensils off the floor, and cupboards under benches should be avoided. It is then possible to keep the floor perfectly clean.

Unpremeditated Lightings. The portrait photographer who aims at variety of effect will do well to keep his eyes open for accidental poses and lightings. Very often an observant eye will discover quite a pleasing effect in the most unexpected quarters, and it is advisable if the picture cannot be secured at once, to make a careful note for future use. Elaborate efforts to secure a certain effect in the orthodox position in the studio often result in a more or less qualified failure, while the impromptu arrangement is successful because of its very naturalness. There are great possibilities in many well-lighted reception rooms, and although it is not often practicable to bring the studio camera to the sitter, a satisfactory negative could generally be obtained with a reflex. With nervous sitters and some classes of children such an informal way of working would go far to secure a natural and unstrained expression. In the studio itself the possibilities of every foot of floor space should be ascertained, so that the sitter could be photographed in the first seat she was allowed to occupy without any apparent formality.

* * *

The Background. In the modern studio the background is not so much in evidence as it was in by-gone days, but it is of no less consequence, and in its simplified form requires a considerable amount of skill to use it to the fullest advantage. As a minimum, a frame, say, eight feet by six, covered on one side with a light grey material, and on the other with a very dark, nearly black, one, may be made to answer for nearly all purposes. If sketch pictures must be made, the light side should be white, and the wall of the studio used as an intermediate tint. A very useful addition to the background frame is a couple of brackets upon which a rod to carry a plain curtain can be fixed. This should not be "draped" in the old-fashioned way, but allowed to hang in straight folds. It is not realised by all to what an extent the depth of tone of a background can be altered by turning the surface to or from the light. This also will be particularly noticed in studios where some form of spot light is used. The light from this type of lamp may be flooded over the background or softened down by the use of colour filters in front of the lamp, thereby permitting many changes in the depth of tone of the background. With quite a dark grey material it is possible in this way to make the ground appear lighter or darker than the shadow side of the sitter's face.

* * *

Bromoil Transfer. When making a Bromoil print for transferring, care should be taken that the surface is not allowed to become too dry, owing to prolonged inking. It should be borne in mind that the ink is gradually drying on the print, and if much time is allowed to elapse before transferring, trouble will be experienced. It should also be borne in mind that too heavy "hopping" with a hard brush is liable to render the gelatine somewhat soft, and it is often from this cause that during transferring the gelatine leaves the original bromide print and adheres in pieces to the transfer. Bromoil prints, which are for transferring, should be inked by the most gentle means, the soft pole-cat hair brush being used with a dabbing action in preference to the hard hog-hair brush, which should only be used to brighten up high-lights, and then as little as possible. All methods of control should be left, in this case, until after transfer, when ink may be added or removed as the worker desires. It often happens that extra depth is required in the shadow portion of a transfer, the high-light and half-tone being satisfactory. This is obtained by re-inking the shadows of the Bromoil only and transferring again. Care should therefore be taken that the print and transfer paper are attached in some manner, so that the transfer may be put back into perfect register. We have found that four pinholes made along the top of the transfer and print when first put into contact serve as an excellent guide when re-transferring.

FLASHLIGHT IN TWO HEMISPHERES.

After a careful study of American photographic literature dealing with flashlight photography, both of single figures and of groups, one cannot fail to be struck by the very different ways in which this class of work is regarded upon the two sides of the Atlantic.

In this country the flashlamp is regarded by most professionals as a necessary evil which is to be employed under protest when there is no other way of securing a negative. The majority of photographers do not seek flashlight work, and as a rule do not show specimens of it. Consequently, few professional workers have given serious attention to the matter, and, there being no demand for efficient flashlight apparatus, little in this way is offered by our manufacturers or dealers.

In America we find a totally different feeling, as a perusal of the photographic magazines will show. Here, in a single number, we may find as many as four different arrangements for making the flash, and these are not the tiny hand lamps which are so generally sold to amateurs, but substantial, yet not ponderous, bags or lanterns, in which the powder can be ignited without allowing the resulting smoke to escape. Herein is the great secret of the American worker's success in this class of work. He is not regarded as a nuisance wherever he goes, and consequently is welcomed where his English confrere is barely tolerated.

It should not be difficult to remove this disparity in practice, either by importing the necessary apparatus or by constructing something which will answer the purpose. There are two distinct types of ignition chamber in general use. One is an entirely flexible bag supported upon a collapsible frame; the other, a folding cabinet which may be compared to a large portfolio, of which one side is opaque and the other is a light frame covered with calico or similar material; side flaps serve to separate the two sides, so as to form a wedge-shaped box and to confine the fumes. A stand is needed to support the whole at a convenient height, and this should be adjustable for standing or sitting figures. The actual lamp may be any of the many patterns on the market, but if electric ignition be possible it is the most convenient in use; it may either take the form of a wire fuse which requires a fairly high voltage to "blow" it, or the special fuses made by Boots, and which are ignitable by an ordinary torch battery. The latter are perfectly efficient when fresh, but are not to be relied upon after a month or two. The wheel and flint, as used in many gas lighters, also work well, and apparatus of this type is very suitable for use in a bag. Ignition by means of a cap, as in the Charles lamp, is also good, if the proper caps are used; toy caps cannot be trusted to give a good spark.

An efficient flash bag of the first type can be constructed by taking an ordinary umbrella frame, which should be strongly made and in good condition, as a basis. The handle of this should be socketed in a strong bamboo or other stick, so that the top of the frame is about eight feet from the floor. This stick may be clamped to a chair or the lower part of the support may be made of a metal

music-stand. The cover consists of fine, rather thin calico, the upper part being made in the same way as an ordinary umbrella cover, but not attached to the ribs. Round the lower edge of this is sewn a curtain or "skirt" about five feet long, with a hem and draw-string at the bottom. At about three feet from the hem a square opening, about fifteen inches by twelve, is cut, and covered with a flap about twenty by sixteen inches, with two or three buttons or other fastening. This is to allow of the manipulation of the lamp, re-charging, etc. The string actuating the ignition release may be brought through the bottom, or a small opening made in any convenient place. If desired, a black curtain may be fixed over the side of the bag which is nearest the camera. This will allow of the lamp being placed nearer the sitter without risk of fogging the plate. The bottom of the "skirt" should be kept closed, as the smoke has a tendency to descend. If care be taken to allow the smoke to settle inside the back, several flashes may be made without taking the apparatus outside. It is, of course, absolutely necessary that the calico be fire-proofed, which is best done by treating with the following solution. The fabric must be treated anew each time it is washed, as washing removes the chemicals.

The solution is made of common salt, 1 oz.; borax, 2 ozs.; and sal ammoniac, 5 ozs.; dissolved in one quart of boiling water.

The dry fabric should be immersed for at least five minutes, and then hung up to dry, without wringing. It is advisable to hang the fabric with the closed top downwards, so that the solution, as it is concentrated by drying, is retained in the part which will be nearest the flash.

It may be necessary that those whose experience has been confined to the unscreened flash, should be made to realise that with a properly-controlled light it is possible, even easy, to produce portraits which can be compared with the best daylight work. In America there are many photographers who prefer the flash to all other lights for child portraiture, the rapid flash securing expressions which are too evanescent for the shortest daylight exposure. An important point is not to over-light. Many of the best single-figure negatives have been made with from seven to ten grains of powder.

WITH A PORTRAITIST IN THE STUDIO.

[In the concluding portion of his paper dealing with the posing of hands and feet in the full-length figure, Mr. J. Effel points out the necessity of getting the sitter into a comfortable position. The correct balance of curved and straight lines is of great importance in full-length, three-quarter length and small groups, and Mr. Effel describes some methods, along these lines, for posing the single full-length figure. The lighting of such a subject is also considered in detail, while some homely advice is given in reference to handling the sitter.]

X. (*continued*)—HANDS AND FEET: THE FULL LENGTH.

As I have said so often before, George, the first thing we have to consider about a full length is the placing of the feet. It is really a very simple matter. Always bearing in mind the rule about the model standing with the weight thrown on one leg, you can scarcely go wrong. The feet are much more amenable than the hands, and an easy "stance" is not difficult to get. I have given you a few illustrations of ladies' feet in easy attitudes, which you ought to put in your scrap book, but if you want a wide range for study, and wish to have at your command all the little tricks of posing cultivated by artists and photographers who have specialised in fashionable portraiture, you cannot do better than study the high class magazines and ladies' fashion journals.

You remember that 15 by 12 group we took at the barracks last month. Well, the sergeant who brought me the orders and collected all the cash is coming in this morning, and I have told Miss Richards to show him up whenever he arrives. We'll take him one or two full lengths, and give him some nice pictures for his trouble, and at the same time we'll have a good model. There's the 'phone, George, from the reception room, see what it is, my lad. What? Sergeant Wilson in? That's lucky; get them to send him up at once.

Good morning, sergeant, I'm glad you got such a tidy little order for the groups, and that all the boys were delighted with them. I hope you have half-an-hour to spare this morning? Good, we want to experiment with your manly figure. It was awfully decent of you to take all the trouble you did in distributing those pictures, to say nothing of looking after the filthy lucre, so I think the least the firm can do is to award you some portraits of yourself. At the same time you won't mind going through a bit of drill for the benefit of my young recruit here. It will be rather a novel experience for you.

Portraits of soldiers, George, have to conform to certain standards, and it is difficult, indeed, almost impossible, to break away from the conventional. A soldier cannot dig his hands in his pockets, or adopt many of the attitudes which might be quite suitable for a mere civilian. I think you would be hard put to it to produce anything startlingly original of a Tommy, but at the same time there are faults innumerable in military portraits, so, as usual, we will pay considerable attention to what you must *not* do. At the war time we were asked so often for full lengths "with nothing at the back" that we had to do quite a lot of soldier pictures with white backgrounds, but for my own taste I never liked "sketches" of khaki-clad figures. I think the sergeant will bear me out when I say that the uniform and boots of the ordinary foot slogger were designed for utility rather than beauty, and that the cut and general effect of the habiliments did not suggest pleasing outlines to the artistic eye. So I would say, use a background that will not show up the outlines too much. That dark exterior, with the nicely-balanced light patches on the shadow side, seems to me ideal for soldiers. See that the foreground is put down with meticulous care, George. If you *do* use scenery, for goodness' sake avoid wrinkles and joins, which shatter the illusion and completely destroy your work in lighting and posing.

Now, just come down here, Sergeant, into the firing line. Stand quite easy, facing me. Will you please note, George that when I am getting a client to pose himself, it is my method to trap him into the position I think suitable, or to get him approximately right without any "handling." Nothing, to my mind, in the work of a portraitist in the studio gives such a bad impression as uncertainty. You need not necessarily start with a preconceived plan indeed, it is usually by talking to a client while moving about that the best poses are got but never build up a composition or part of one and then abandon the original idea. Occasionally I make a mistake with a position and realise it in time, but I never let the client know it. I just snap away without drawing the slide, and then proceed to the better pose. Make everything seem simple. When I asked our warrior friend to stand there and face me, there was no accident in the fact

that I was standing a good bit to the side of the studio. Most persons dislike being pushed about, or "handled," and I cannot insist too much that you avoid all unnecessary pawing. At the same time, don't spoil your chance of a good negative because you did not alter some little detail. Always show that you are masterful. If you go to stroke a timid animal, you may run the risk of being bitten if you approach it in a hesitating manner; and a sitter may also feel like biting you. Good clients who want artistic work will, however, invariably be found to be very patient and gracious. When I was a mere boy I had one day to photograph a countess and her two little children. No appointment had been made, and it was explained to the lady that only a junior assistant was available. She decided to risk it, and I was let loose. For a shy boy to be suddenly called upon to photograph a noted beauty with her children was enough to put me into a state of blue funk. I fumbled about, dropped stops, fell over my feet, and was generally uncomfortable, until, with great kindness, the countess told me in a laughing way to "just pull me about any way you like; I'm sure you'll manage beautifully." I will say nothing of the results, except that one of them was subsequently reproduced. What I am endeavouring to show is that had I been treated in a haughty manner, nothing but double exposures and other blunders would have resulted. Give the clients confidence in you, George, and you may safely "handle" them sufficiently to get good pictures.

Now, just as our model is standing there (he is quite comfortable on his feet), I wish to draw your attention to a point of great importance in all full length, three-quarter length, and small groups, the correct balance of curved and straight lines, and the underlying rule that will guide us in this particular is very simple, and I want you to always have it in your mind, particularly when dealing with standing figures. The bold sergeant stands there, his cane under one arm and the other hanging loosely by his side, his pipe held in this hand. Is the position right? Will that look well in a photograph? If it isn't right, then what is wrong, and why is it wrong? I can see you are not quite satisfied, George, but I don't want you guessing, so we will start all over again with our composition, and that will put you on sure ground.

A man stands on one foot at a time, and the weight is thrown on one leg. That leg is rigid and straight, the other is more or less bent. I am merely recapitulating briefly what we have gone over before. Now look at the sergeant. He is standing on his left leg, but his left arm is also straight, and what is wrong with the composition is that the straight lines are all on one side of the picture and the curves on the other. In standing figures, think of the figure 8 as you draw it. The top right-hand curve flows into the lower left curve, and *vice versâ*. The result is a well-balanced figure. Well, just draw the figure 8 with your subjects. Assume that one arm will invariably be bent more than the other. Take this, then, for a good working rule; place a straight leg and a curved arm together, *never two straight limbs or two bent ones on the same side of the picture*. Think constantly of this rule, George; look through scores of old full-lengths and see if the artists worked on my method, or just left the harmony to chance.

Poor old Sergeant Wilson! You've let yourself in for something this morning. You're quite enjoying it? Well, it's good of you to say so. We'll just proceed to put you through it thoroughly. Of course, you must promise not to give the game away. Well, then, change the pipe to the other hand, and put the cane under the opposite arm. There, George, there's the position reconstructed in the fundamentals. You see the body is turned considerably away from the light. The figure is good, and I want to show that. Just a trifle too much ong-bong-pong. Ah! that's better. It is common practice, George, to get stout figures to lean forward. It isn't so easy with the ordinary male subject, but a soldier who is too fat can be taken quite successfully to hide the unpleasing feature. We'll just illustrate the point. Bring both your hands in front, Sergeant, and hold your cane. No, not like that, with the hands wide apart; that might do all right with a slim sort of chap if we wanted to show his waistline, but it is camouflage we are aiming at here. Clasp your hands together. Now let me manipulate them for the benefit of my pupil. Fetch me down a walking-stick, George; this little swagger article is too short for what I am endeavouring to do. Put both hands on the stick, Sergeant, and hide one with the other. Now throw the body well forward, and press the hands down; quite a good way of steadying up an irascible and fidgetty old major, who would wither us up, George, if a head-rest was mentioned. See now, the upper arms of our model are straight by his sides, and from the elbows converging downwards to the hands, the fore-arms make a V shape across the equator of "little Mary." We'll take one like this, and then, before we do another position, George, I suggest that you take a right bad one, conserving all the width of the figure; the two will then be good examples for your scrap-book.

We have not yet considered the view of the face or the scheme of lighting. In posing, I start from the feet, and in lighting I commence in comparative darkness. I assure you, George, you cannot improve on those sound methods. Well, what think you of Sergeant Wilson's face? A fine type of the "roast beef of old England" countenance with very slight projections, so we must keep the lighting narrow. The body is turned a good bit away from the light, so we will turn the head back again a little, but not too much, as that would shorten the neck, which, as you see, is short enough. The face, at what we speak of as three-quarter, will about do—keep the second ear out, George—and the eyes slightly in advance of the turn ought to look straight at the camera. I have noticed that many splendid camera artists are very careful with the lighting of busts and half-lengths, but when they get up to full lengths the studio is invariably flooded with light. This tendency is due, I am sure, to adherence to the old "axiom" about the light coming from one unbroken source—an axiom, by the way, the breaking of which did a great deal to build up the reputation of Reutlinger as a fashion-plate photographer. Thanks largely to manufacturers who have magic lanterns to sell, we are now breaking all unbreakable rules. A khaki uniform requires a good flood of light, which for the face we have here would be too broad. Obviously, in the old-fashioned "all-one-piece" style of lighting both the face and the clothing could not have been treated as they would have been, had they been separate studies. As in a full length one works for the general effect, it is easy to see why full lengths are so frequently over lighted. Of course, there must be a little give and take between what is right for the head and what is best for the whole figure in the way of lighting, but with modern methods much better general effects can be obtained. In the present case I light the figure with a comparatively far-away front light, and then finish off, as it were, with a little bit of good direct severely side light. With all faces of low projections, work for relief; it has long been a practice with me to get a touch of light behind such sitters. I leave a fairly good bit of shadow on the face here. With a fat face, resist the temptation to use the reflector much. Well, then, there is the lighting and the position. Is there anything wrong, or may we just snap away? Yes, there is the matter of the hands again. Turn them outward, so that if the subject looked down he would be regarding the backs. You will see now that only the edge of one hand is really seen by the camera. In this or similar positions a glove—not a pair—may be used, but remember that it looks like a glove and not an old rag. Well, then, go ahead, George, and then build up another full-length as different as you choose. You have a fine chance here with a very docile model, so take full advantage of it. There was a neat little revolving platform of about 3 ft. in diameter

which I saw in the studio of a clever Italian worker. This photographer maintained that a properly-posed figure should be like a statue—that is, to look right all round. Certainly it was a clever adjunct to the student. Well, just make your victim turn about for you as you want, and select the best you can. I would say after that, take a three-quarter length and a bust without cap.

Well, Sergeant, I leave you at George's mercy. Call round this day week and we will have proofs ready for you. Cheerio!

J. Effel.

PHENOSAFRANINE DESENSITISING WITHOUT STAIN.

[In the current issue of "American Photography," that of December, 1922, pp. 756-762, Mr. H. G. Cleveland describes a modification which he has worked out of the original phenosafranine desensitising process whereby the drawback of the residual stain in the negatives is largely obviated. He adds formaline and soda sulphate to the desensitising bath and finds that the dye stain is then rapidly removed in the ordinary washing of the negatives and that the desensitising bath also keeps better.]

It has been but a short time since phenosafranine solution has been recommended for desensitising plates and films, and much has been said regarding this operation. Already other dyes have been discovered having similar properties and which may be superior to phenosafranine for the purpose. The one which seems to have the greatest promise for this purpose is pinakryptol green, the others have not proved as satisfactory generally as the phenosafranine.

The main objection to the phenosafranine bath has been its tendency to stain the plates or films severely, and this stain has been difficult of removal. Many attempts have been made to overcome this fault. These attempts seem to have taken the form of either finding other desensitising solutions with less staining tendency, or discovering some bath which would readily remove the stain, rather than the addition of some other substance to the phenosafranine bath to remedy this condition.

In reference to the method of putting the plates or films through another solution to eliminate the stain, this adds one extra operation, which should be avoided, if possible, and also the chemicals suggested usually have a tendency to soften the film, which, to say the least, is apt to be very annoying in hot weather.

The following method of preparing the phenosafranine bath eliminates practically all of the stain; what little stain is present is removed in the wash water or remains in such small quantity as to make no difference in printing from the negatives. Anyone who has tried the phenosafranine bath as usually recommended or sold commercially will immediately discover the slight amount of stain obtained with the bath as here recommended, which is made as follows

Stock Solutions.

A.	Phenosafranine (water soluble)	20 grs.
	Water	8 ozs.
B	Formaline, 37 per cent.	½ oz.
	Sodium sulphate, dry (Glauber's salt) ..	1 oz.
	Water to make	9 ozs.

To 9 ozs. of B add 1 oz. of A, to form the working solution *

This working solution should be used as a separate bath, and the plates or films placed in it one or two minutes before starting development. They may then be given a short rinse, and development and fixing proceeded with as usual. As this bath also has a tendency to harden the plates or films they should be removed in two or three minutes in order that they may not become too greatly hardened. On the other hand, this property is of great advantage in the summer time, as the films are conveniently hardened while being desensitised, and therefore do not soften in the developer, in the hypo, or in the wash water. For this reason no hardener is required in the fixing bath. The hardening in two or three minutes, due to the formaline, is not excessive, and films put through this bath over a year ago show no signs of deterioration.

When working as above indicated, the development is slowed somewhat, but the correct time of development may be readily determined by one or two trials, and to make certain of the developer acting with uniform speed the time that the plates or films remain in the desensitiser should be kept as uniform as possible. To avoid streaks which might occur, it is recommended that after the plate or film is removed from the desensitiser it be well rinsed for a couple of seconds, placed in the developer, and the developer immediately rocked or the film kept in motion for about half a minute in order to be sure that the developer is acting uniformly. This same procedure should be followed when placing the negative in the fixing bath.

When using orthochromatic emulsions, the plate or film may be developed within two or three feet of a W. & W. OO safelight, which is the safelight used for bromide paper. Panchromatic emulsions, such as W. & W. Panchromatic plates or Eastman Panchromatic film may be developed within the same distance of the same light provided a sheet of cardboard is interposed between the light and the plate, and the plate is kept in the shadow of the cardboard. While the plates and films may be developed in the light as indicated, some care should be exercised to avoid unnecessarily exposing them to the light. For this reason it is advisable to keep the tray covered part of the time. This is especially so in the case of the panchromatic emulsions, which are so extremely sensitive that a little extra care should be taken in handling them.

Another advantage of the desensitising bath is the fact that it eliminates to a great extent chemical fog due to the developer and also fog due to an unsafe light or unsafe dark room, as the desensitising starts as soon as the plate or film is placed in the phenosafranine bath. Because of this elimination of chemical fog and fog from an unsafe safelight, the negatives are much cleaner than is usually the case, and this is especially noticeable in the development of the panchromatic emulsions. For this reason alone, it is advantageous to use the desensitising bath with the panchromatic emulsions, even with the regular green safelight which is recommended for use with them. In my own experience I may mention that in developing panchromatic plates and films by tray, using the green safelight provided for the purpose, I not infrequently obtained fogged negatives, which I attributed to various causes, old emulsions, leaving the films too long in the plate holders, etc., but not once did I doubt the safety of the dim green light. In contrast to this state of affairs, I may say that since using the desensitising bath mentioned above I have obtained clean negatives free of fog, notwithstanding the fact that I have been developing the panchromatic emulsions with the tray close up to the dim green light provided for the purpose, and without covering the tray at all during the full time of development, lasting from three to seven or eight minutes.

Of course, the plates or films must be placed in the desensi-

* This solution is considerably stronger than that usually recommended. From the above quantities one pint of desensitising solution contains 5 grains of phenosafranine, while the usual strength is 1 grain per pint, or approximately 1 in 10,000.—Eds. "B.J."

tising bath in the dark or in a light safe for the plate in use, the brighter light being turned on after they have been in the solution for a minute or two. If the dark room is equipped with electric light a convenient method of working is to attach the safelight and the brighter light to a double socket, starting desensitising in the safelight and then turning on the brighter light. The objection may be raised that the plates or films must be started in the dark or by a weak light, and that being the case, they might just as well be developed in such light; but this objection is not well founded, as but little light is necessary for placing the plates or films in the dye bath, and the light is considerably brighter during the development of the image. Therefore the eye strain is considerably less in the inspection of the image, and the image may be more carefully inspected.

In order to avoid staining the fingers in the operation, it is advisable to handle the plates or films in clips or hangers and keep the fingers out of the desensitising solution. In practice this should present no difficulty.

Because of the hardening properties of the desensitising bath, the emulsion becomes tough and strong, permitting rough handling, eliminating hot weather troubles as already mentioned, decreasing the possibility of damage to the film, permitting the use of warm developers and developers with caustic or other strong alkali, and allowing the possibility of rapid drying.

Another objection to the regular phenosafranine bath as usually recommended is the fact that its keeping quality after once being used is not very good, as considerable mould often forms on it, necessitating filtering before further use; but with the formaline bath recommended above, the keeping quality is very good, and this may be used over and over again and kept indefinitely, simply adding more solution from time to time to bring the quantity up to the amount desired.

The advantages of the above desensitising bath may be summed up as follows:—

Desensitises plates or films, permitting development of panchromatic or orthochromatic emulsions in bright orange light.

Does not stain plates or films unnecessarily. No after treatment necessary.

Enables more accurate determination of time of appearance in factorial development.

Relieves eyes from severe strain of developing by weak light.

Enables better judgment as to whether negatives are over- or under-exposed, and amount of development necessary in each case.

Prevents fog from an unsafe light or unsafe dark room.

Contributes to prevention of chemical fog. Prevents hot weather troubles.

Enables use of warm or strongly alkaline solutions.

Toughens films, enabling rough handling with less possibility of damage.

Permits rapid drying of negatives. Keeping quality of solution is excellent.

A trial or two with the above method of procedure will readily demonstrate its merits and will probably result in its adoption.

H. G. Cleveland.

FERROTYPE WITH A FIELD CAMERA.

To convert the usual type of field camera into an efficient piece of apparatus for "while you wait" photography requires but a minimum of mechanical skill. With the aid of a few simple tools, and the help of a tinsmith for the metal parts of the apparatus, quite a capable job may be made. Such a camera made by the writer has been in use for the past two seasons, and has fully justified the amount of trouble expended upon its manufacture. The camera itself may be of either ¼-plate or ½-plate size; the writer's camera is ½-plate. The measurements given are intended for that size, but a ¼-plate camera may be easily adjusted for the work in a similar manner. The camera, however, must possess a wide angle movement, allowing the back to be pushed forward towards the lens, and clamped in this position. The baseboard therefore forms a platform upon which the box constructed for development, etc., rests. A short focus lens must be used, and one which is capable of giving good sharp definition over the small size of plate.

The box is the first portion to be made, and this is constructed of stout 3-ply wood. The base of this box is 8 ins. by 7½ ins., the narrower side being altered, if necessary, to fit into the back of the ½-plate camera. In my particular instance the camera back is 7½ ins. square The rear portion of this box B is of fairly stout wood. ⅜ in. thick, and has a U-shaped section cut out to allow the hand to be easily inserted into the box.

The top of the box is open along the sloping sides, as in fig. 2, with the exception of a strip C which extends across the top for the attachment of the twill covering. In the front of this box a circular opening is cut of 5 ins. diameter and a piece of 3-ply wood cut to fit exactly. Two other circular discs are cut, one 6 ins. diameter and the other 5½ ins diameter. In the centre of each of the discs a rectangular opening is cut corresponding to the size of the plate used and allowing a small rebate all round. In the present case the opening measures 2¼ ins. by 1⅝ ins.

The three discs are now fixed to the front of the box by screwing them together, but the smallest disc which fits in the circular opening is first covered with a thin piece of cardboard to make it slightly thicker than the box front. This allows a little play between the discs and the front of the box, and permits the discs to turn easily when in position. These discs are shown in section in fig. 2. The 6-in. disc which is inside the box has a notch cut out for a quarter of its circumference, and stops are affixed to the front board to allow the disc being turned over a right angle and so reversing the position of the plate.

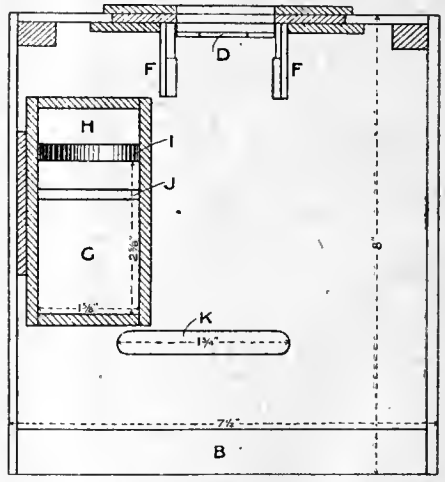

Fig. 1.—Plan. B, back of attachment with U-shaped portion cut away in centre. D, focussing screen and plate holder. F, metal plates holding focussing screen when folded back. G, magazine for plates. H, space for finger when removing plates. I, division with U section cut out. J, small strip of wood, to keep plates off bottom of magazine. K, opening to tank.

A focussing screen is attached to the rectangular opening by means of a metal frame to which a hinge is soldered. To allow the focussing screen to fit exactly into position one leaf of the hinge

is reversed, by removing the pin and turning the leaf round. The screen is shown at D. This screen is held by a clip E, and accommodates the ferrotype plate during exposure. On either side of the focussing screen triangular metal plates F are fixed. These

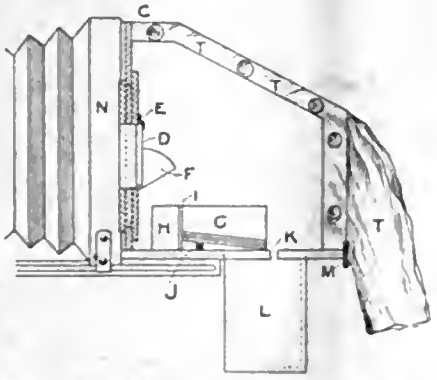

Fig. 2.—Side elevation. C, flat strip on top of box. D, focussing screen. E, clip for holding screen and plates in focal plane. F, metal plates for holding D when folded back. G, magazine. H, space for finger I, dividing strip. J, small strip of wood. K, opening to tank. L, tank. M, stop for tank. N, camera back. T, twill covering.

plates have rebates on the inner sides which hold the focussing screen when it is folded back to allow a plate to be inserted.

On the base of the box a small magazine is constructed to hold fifty plates. This is shown at G, and is made of 3-ply wood lapped at the joints to make a light-tight job. This box is 3¾ ins. by 1¾ ins. internal measurements, as shown in fig. 1, and the front portion H is left clear to allow the finger to be inserted when it is desired to lift out a plate. The dividing strip I has a U-shaped portion cut out from the top, reaching nearly to the bottom, thus allowing the edges of the plates to be exposed and easily lifted by the finger.

A small strip of wood J, ¼-in. square, is glued across the box to keep the plates off the bottom. A light-tight lid is made (with a hinge of thin leather or linen) to cover this plate magazine entirely. The lid is made fairly heavy, so that it will close automatically after a plate has been taken out. Slightly behind the plate box and in the centre of the apparatus is the slot K, which is 1¾ ins. long and ¾ in. broad. This communicates with the developing tank L. The tank consists of a 1-lb. glass jam jar, which is entirely encased in a tin lining, the flat top of this tin being extended ¼ in. on either side, with a slide of 3 ins. in front and 1 in. behind the tank. This is shown by the dotted lines in fig. 2 above the tank.

The glass jar is held in position by a rubber band round the upper portion which fits tightly in the tin case and so prevents movement. At right angles to the extension at the rear of the metal casing of the tank a stop M is fixed. This prevents the tank from being pushed too far in front of the slot K. The overlapping metal portion of this tank fits into a wooden groove screwed to the base of the box, and is securely housed to prevent entrance of light.

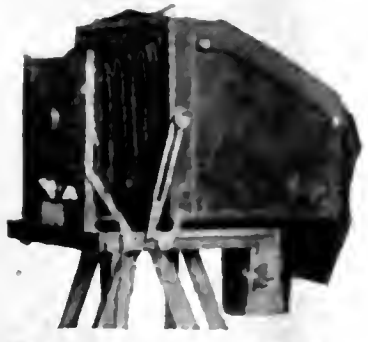

Fig 3.—Camera with attachment fitted.

The whole of the top portion of the box is now covered with a double thickness of black twill, as shown at T, fig. 2, an opening being made at the rear to allow the hand being inserted when putting the ferrotype plate into position. Drawing pins are shown along the top and side of fig. 2; these hold the twill in position and allow easy removal of the covering if necessary.

Focussing takes place by observing the screen through the opening at the back of the box, the platea being covered by the lid of the magazine during this operation. It may be necessary when converting one's own apparatus to alter the measurements slightly, but once the general idea of the attachment is understood, the actual making of the fitting will become quite simple. A photograph of the complete apparatus is reproduced in fig. 3, from which it will be noted that it is quite neat in appearance, while in actual use it is as simple as it is efficient.

C. J. Sims.

DESENSITISING IN ITS COMMERCIAL ASPECT.

(A note in the current issue of the "Photographic Journal.")

In a short paper which I read before the Pictorial Group a few months ago, I lamented the fact that photographers, generally speaking, lacked the experimental sense. Science progresses continually, but it is always a matter of some considerable time before the teachings of science are applied in actual practice. As an instance of this there is no better example than the thiocarbamide process in the development of lantern slides, long so ably advocated by Mr. Dudley Johnston, though the process was worked out many years ago by Dr. C. E. K. Mees.

Much the same thing is apparently taking place in the matter of desensitising prior to development. Careful inquiry among many of my friends leads me to suppose that, in spite of the publicity given to it in the Press, it forms a *terra incognita* to amateur and professional alike. This is not as it should be, for to the photographic worker nothing is calculated better to serve him than desensitisation applied as an essential part of his photographic routine.

When Mr. Storr, some two years ago, first demonstrated before an audience at the Royal the desensitising properties of phenosafranine, I realised that this gave the professional photographer in particular quite a new power in his operations, not only providing extraordinary convenience in working, but also serving to shorten very materially the time occupied in the development of large batches of negatives. I immediately tried the dye, and though the desensitising from the practical point of view is perfect, yet this particular dye has unfortunate staining properties which render its use inadvisable and, in my opinion, from the commercial point of view, impossible.

When a dye possessing such revolutionary properties as phenosafranine is discovered, it is hardly necessary to remark that science immediately sets to work to find other dyes having the same property, and in view of the enormous number of dyes at present known, it was only a matter of time before several others were found. One such dye formed the subject of an able article in the "British Journal of Photography," by Mr. R. E. Crowther, last July.

Mr. Crowther, in his article, dealt with the properties of three different dyes; and as from his remarks the third (Pinacryptol Green) appeared to be the best, with some difficulty I laid in a supply for a practical trial, the trial proving such a success that it caused me to institute quite a new dark-room routine from which now I should be sorry to depart.

The dye, as bought, is a metallic-looking powder, having something of the characteristic appearance of iodine. It is very readily soluble in water. Both the original instructions and Mr. Crowther in his article recommend a solution of 1 in 5,000 for use. Here let me remark that, through an oversight, I made up my first solution of just half this strength, and as I did not get the least sign of fog on the negatives, I have used it at this strength ever since.

Turning now to the practical side, I must refer at short length to the ancient method of development as practised in my everyday business. In this the 12 by 10 plate is the standard size, and they are used in very large numbers; it is quite an ordinary matter to find anything from nine dozen to a gross awaiting development in the afternoon. These were developed in a wooden dish four at a time, and development under these conditions is inclined to become intolerably tedious. Tanking them I found unworkable, though I tried hard to make it a success.

Pinacryptol Green, however, has changed all this. The dark-room sink now carries three tanks. No. 1 is the desensitising tank, Nos. 2 and 3 contain developer. These, with a dozen racks made to hold twelve 12 by 10 plates (which are spaced half an

inch apart), constitute the complete equipment, which, from the area point of view, occupies far less space on the sink than the old wooden dish.

Confronted with a batch of exposed plates, a rack is taken and filled with a dozen plates in a red light, and it is immediately placed in the desensitising bath for a minute. Bubbles adhering to the film in this bath were at first a nuisance, as this left small circles of film that were not desensitised. In this connection I found that dropping the cage of plates for an inch or so on to the bottom of the tank dislodged the lot, and the negative developed up free from the little circles of fog where a bubble had persisted.

After a minute in this bath a strong yellow light may safely be turned up, and the rack of plates is placed in the developing tank, and a second rack of plates can, if necessary, be desensitised in a similar manner. A third tank could of course be run, but personally I find that two developing tanks with 24 plates is as much as one can look after properly without slowing down the developer.

The light used for developing is a very strong yellow, using one thickness of the commercial yellow fabric only. The whole dark-room is flooded with light, so much so that it is easily possible to read small print in any part. The gain in comfort is incalculable, and as the negative can be watched most critically in all stages, it is possible easily to keep them very level in grade.

The negatives are absolutely free from fog, though the desensitising solution is only half the recommended strength. Panchromats, films and the usual run of studio negatives all go through the dye, and all respond just as readily.

I have not yet observed the least staining propensity of this dye; both the plate and the fingers are quite unaffected.

It may be asked after all this, "Where is the gain?" There is first the enormous saving of time; in my case the saving is in the proportion of one to five, *i.e.*, I find I can get through five times the number of negatives that I could under the old conditions. Then the brighter illumination of the dark-room is a boon only to be experienced once to realise what a comfortable place a dark-room may be under modern conditions; it is a boon worth almost as much as the incredible saving in time. Then again, as it is possible accurately to judge the density of a negative, it is easily possible to keep them of a very level quality—always a matter of considerable difficulty in the old days of shrouded gloom.

I am not claiming that desensitising is much of a help in cases where an occasional plate only is developed, but for anyone who is accustomed to develop plates in bulk it will be found to deprive photography of one of its worst horrors—the uncertainty and gloom of the dark-room.

A. C. Banfield, F.R.P.S.

Assistants' Notes.

Notes by and for assistants will be considered for this column. Payment for accepted contributions is made on the first of the month following publication.

Improvised Darkrooms.

It is in practice surprisingly easy to dispense with the formalities of the darkroom when the exigencies of circumstances make it necessary. The precautions which are quite rightly insisted upon at home may be ignored, when one is travelling and has to produce urgently wanted work at once, without appreciable harm.

In the course of the writer's experience he has frequently had to convert into temporary darkrooms rooms primarily intended for other purposes altogether. Bedrooms are usually the most easily converted, and here one is assured of almost unlimited privacy; but bathrooms and outhouses have also been utilised quite satisfactorily, subject to the permission of an amenable host. The arrival of darkness makes things easier, of course, but the exclusion of light from an ordinary room, sufficient for practical purposes, while the sun is shining brightly outside, has also been satisfactorily accomplished.

When it is remembered that the damage to a plate comes, not from reflected light, but from the rays that fall directly upon it, the problem is simplified. One may occupy a room outside of which is a street lamp, the light from which filters in even when the blind is drawn and the additional shield of a thick curtain or blanket provided. The risk of fog is in this case negligible, if development is carried out in the corner farthest from the window and the body interposed between the dish and the source of light. The developing dish must, of course, be covered throughout the operation, except for a few brief moments for inspection, and unnecessary exposure of the plate in any way avoided. Within these limits there are few buildings—even, as falls within the writer's experience, an old barn, which cannot be made light-proof after sunset.

Fortunately it is of rare occurence, but it sometimes happens that time presses to such an extent that to wait for nightfall is out of the question. The writer is thinking more particularly of newspaper work, where his experience has in the main been garnered. Many are the expedients to which resort is made in this case. It is often possible to discover a room—perhaps a cupboard—into which light has but one way of entrance, through the crack at the bottom of the closed door; or a room which can be rendered totally dark but for the window, which, however carefully sealed, admits a stray beam. A box should be obtained, and stood on end with the base towards the window. It will be found that development can safely be conducted in the interior of the box, the sides and one's own body sufficing to make it light-proof, the dish being covered as an additional precaution.

A mastery of the technique of time development is invaluable in the circumstances I have described. A watch with an illuminated dial should be a part of the equipment of every photographer. If it is lacking, the passage of time may be observed by retiring at intervals into a corner of the room and inspecting the face by the light of a carefully shielded match.

The devoted adherent to the inflexible rules of the comfortable, well-fitted darkroom will regard some of these details as little less than heresy. But they have to be practised on occasions, particularly by the pressman, and, granted reasonable care, they impair but little the quality of the resulting negatives.—G. F. W.

Photography inside Aeroplanes.

Having had occasion to photograph apparatus fitted inside aeroplanes of many kinds, some notes may be of service to anyone called upon to do the same. Owing to the inflammable nature of the machines, flashlight is ruled out entirely, however dark an interior may be, and it is an advantage to slip a piece of mirror into the camera-bag, to be used in reflecting a beam of light into dim corners.

The camera I prefer is of a light folding type, not larger than half-plate, as one requires depth of focus, but exposures are liable to be lengthy so that it is best to rely on enlarging from a fairly small plate.

Although not fond of the tubular tripod, for this work it has advantages, provided it is firm enough for the camera to be used. Its blunt points will not damage the canvas, of which there is a great deal, and the legs can be adjusted with little fear of slipping about as a wooden tripod does when the points are not pushed into something. Seldom can one obtain a level surface to stand the tripod upon, so that each leg may be on an entirely different plane if the camera is to be upright. Frequently it has been found necessary to tie the legs to any convenient projections, or even to do away with the stand and to lash the camera to some wires and cross bars with a large number of strings.

The attachments sold for clamping cameras to improvised stands are not much use, as there is so seldom anything just where one wants the camera, to attach it to. Individual ingenuity is a great asset in this work, as one can spend half an hour in tying strings, but the camera may be either still wobbling or perhaps be quite firmly pointing a little off the subject.

Focussing often is all but impossible. The method I used was as follows: Having measured the longest diameter of the subject it did not take much time to calculate what lens to use to get it well on the plate at the greatest available distance (this is always short) allowing room for the camera itself but not for the operator. One could usually allow an inch between the back of the camera and the wall, etc., or else arrange to have that inch temporarily and to push the camera right back after putting in the slide.

The camera was rigged up as well as the conditions allowed opposite the middle of the subject, and a pocket flash-lamp was laid on some outside bit of it. The image of the filament could be seen by placing a bit of mirror just behind the ground glass against the back wall. After a few jobs of this kind I purchased a dental mirror, *i.e.*, a tiny concave mirror fitted at an angle with a long metal handle, and this was found an acquisition not only for this particular work, but for many other cases of difficult

interiors in cramped quarters. This method enables the operator to stand beside the camera and still ensure getting his subject correctly "filled" on the plate. An outside spirit-level is sometimes necessary if the subject includes vertical lines. In cases where even the method of focussing described was not possible, one could measure with a piece of string the approximate distance from lens to subject and focus on a similar distance before placing the camera in position.

The "dope" and the general character of the subject render panchromatics essential, but the use of a filter is seldom practicable owing to the long exposures.

For photographing exterior details of planes one can usually get the use of ladders and portable platforms used in the hangers and occasionally a telephoto lens of the adjustable type is an asset for detail work. In any case it is advisable to arrange matters so that one does not stand, when exposing, on the same support as the camera.

The slightest movement will often start the plane or the platform swaying, though the wise photographer will have seen that the "bus" is jacked up before starting operations.

If there is included in the subject one of the small "propellors" used for generating current for the wireless set, it is a very good plan to insert a pointed match somewhere round the axle when no one is looking. These propellers have an annoying habit of giving a half-turn every now and then when one's back is turned. The wedge can be easily removed after exposure (surreptitiously if thought advisable).

D. Charles.

Exhibitions.

ROYAL PHOTOGRAPHIC SOCIETY.

A series of house exhibitions have been arranged by the Royal Photographic Society, and it is proposed to place upon the walls at 35, Russell Square, W.C., a continuous display of prints by prominent workers. The visitor will thus be assured of an interesting exhibit whenever he is able to visit the rooms, a point which will help, not only by giving prominence to the work exhibited, but by popularising the society itself. On Tuesday last the work of three prominent photographers was placed upon the walls. In the lower exhibition room some prints, "An Old Master of Photography," John Forbes White, taken somewhere about 1855, are on view. This collection was suggested by Mr. P. C. Tilney, who himself opened the exhibition. Together with these are hung a series of enlargements, coloured in pastel by Dr. D'Arcy Power. This latter process was described recently in our columns ("B.J.," September 22, 1922, p. 583), when Dr. D'Arcy Power demonstrated the process at Croydon.

In the upper exhibition room Mr. Frederick H. Evans has placed a number of his beautiful prints of Westminster Abbey on the walls. These are all platinotypes, a process which suits this type of work admirably, and allows the quality of the negative to record its beautiful gradation to the full. Mr. F. C. Tilney has reviewed the exhibits and his remarks will, we are sure, be appreciated by all who visit the exhibition.

* * *

An Old Master of Photography.

In the succession of exhibitions with which the R.P.S. animates its members there are occasionally collections of work which stand out as of supreme importance. Nothing less could be said of a show of prints made 67 years ago by a man of great reputation among scholars, an intimate friend of eminent painters, and an authority upon ancient and modern painting.

John Forbes White was a contemporary of D. O. Hill, whom he knew well. At the age of 24 he took up photography, the brilliant pictorial possibilities of which doubtless proved an irresistible lure to one whose life was a matter of art-impulses. For two years he worked, producing prints by the "waxed paper" method, a development of the calotype used by Hill. His subjects were chiefly architecture and outdoor views. A few of his negatives are on view, shown as transparencies. In its class his work is as strong and fine as Hill's.

Yet although everybody has heard of Hill, no one, photographically speaking, had ever heard of White before the good fortune that befell me of discovering this buried treasure. White's name does not occur in any book on photography, nor in any historical catalogue. The Crystal Palace Exhibition knew him not, although some prints appeared in the great Glasgow Exhibition. "But the whirligig of Time brings in his revenges." Making a call upon a neighbour in my village two or three years ago I was surprised to see a number of architectural photographs hung upon a staircase. "What are these; D. O. Hill's?" I asked. "No, they were done by Dr. White, of Aberdeen, in the old days." Such a find could not be permitted to go unrecorded in photographic annals, and I put the suggestion to Mr. Harrower, the photographer's son-in-law, that they should be exhibited. In due time this has been brought about, and I am not a little proud of having been the humble cause.

Judged by modern standards these works would be deemed poor photographs. They have no skies; they are not rich in half-tones; they are generalised into lights and darks, and what half-tone there is comes of fine admixture of the black-and-white elements, with a consequent granulation of texture. But those early methods, laborious, fortuitous, evil-smelling as they must have been, did produce pictures when the right man was behind the camera. And are modern camera pictures any better, for all their infinite subtlety of tone-differentiation which science has coaxed out of material by chemical research? What we have always admired in Hill—the downright light and shade aspect, such as a strong etching gives, in good hands—is seen equally in these other old works that are new to us. Their characteristic is virility, which embraces nevertheless a perfect delicacy. The interesting fact about the negatives is that they reveal much more detail and nuance than the prints show. The printing paper seems to have been responsive up to a point only; all below this degree of tone the paper seems unable to register, but all above it is precise enough. But this, as it happens, is exactly the method of the painter. So Velasquez looked upon his subjects. This is, in fact, the secret of the charm which lurks in the fine broad, impressive sheets of shade, that give such masculine design and effect to the works of this period, and possibly it was this fascinating "treatment," this truth to actual human vision, that appealed to Hill, the painter, and to White, the Encyclopædia Britannica authority upon Velasquez and Rembrandt.

That White felt and revelled in the richness of these generous shadows is obvious from the masterly effectiveness with which he built them into his compositions, as well as from the selection of the day and the hour when they should be most eloquent in sharp relief of sculptured detail and mere mural inequalities. Indeed, the quality of textures is one of the notable characteristics of the prints.

Apart from the fact of their antiquarian interest, the artistic fascinations they exert will make a strong appeal to those who aim at exploring the resources of photography as a pictorial medium.

Photographs by Frederick H. Evans.

After an absence of at least a decade from exhibitions, Mr. Evans's admirable work may come as a surprise to all but those who remember his triumphs in the past and have seen his output in the interim. The long series of views of the interior of Westminster Abbey are certainly a wonderful achievement. One can imagine nothing finer or more complete as a set of illustrations of the architectural, historical, and archæological aspects of the great cathedral. As records of structure and ornamentation, and even of the shafts of light which, in piercing the gloom century by century, may be regarded as permanent features of the vistas, these photographs are unsurpassed. There is scarcely an inch of carving or sculpture of any note that Mr. Evans does not attack, however remote or obscure it may be. Groining, "pendentives," lost in a lofty twilight to the normal eye, he illuminates and brings into view. Tombs that are hidden in murk and mystery start, blushing, into the adventitious limelight of his long exposures. We see all by the management of his magic, which is both telescopic and microscopic.

Over all he sheds the fascinations of his photographic quality, in making every shadow alive with detail and his thousand and one tones in infinite gradation—superb!

Mr. Evans, himself, speaks of these works as pictures. And in the sense that anything which depicts is a picture, they certainly are. But the elements of pictorialism do not lie very much on the road Mr. Evans chooses in these views; for they are in the nature of radiographs of the hidden anatomy of the fane. A discussion between a few friends on the opening night of the show, when Mr. Evans exhibited lantern slides of the views, raised these

points: What is the pictorial charm of the Abbey? Does it not lie in the very gloom which Mr. Evans dissipates? Does the eye, as it revels in the poetry and mystery of towering piers, see anything but a thrilling play of darkness and lightness? As soon as the enchanted beholder adjusts his vision from the broad responsiveness to the acuter searching of detail, he has finished with the picture, and become the antiquarian enthusiast or the connoisseur of carving.

But, said one gentleman, a man could see all the detail when his irides were sufficiently opened. Another observed that a camera in a coal-cellar would give every detail if the exposure were long enough, and if there happened to be the faintest modicum of light; but a man would first starve, and then rave, and finally die before he saw as much, and then it would matter little how much he had seen.

It seems to me to be a point of photographic ethics—this "exposing of the shadows" fetish—that is, if the *picture* is the thing, and not the *record*. Mr. Evans admitted that one tomb was in darkness; but he showed it as though transfigured by a lightening flash.

In a few of the exteriors, particularly of Durham, the pictorial aspect is easily established, because the exposure coincides more nearly with the normal eye receptiveness. These have the pictorial charm which, when the fortuitous concourse of circumstances exists which pure photography requires, no one can render more delightfully than F. H. E.

PHOTOGRAPHIC PASTELS.

A third exhibition consists of examples by Dr. D'Arcy Power of his method of treating the photographic basis of a print in such a way as to admit of the application of pastel work for a coloured effect His method has already been commented upon in these pages on the occasion of his lecture at Croydon. I very much liked the feeling and colour of a seascape, wherein the basis had certainly disappeared altogether. These house exhibitions remain open till the end of the month..

F. C. TILNEY.

PORTRAITS OF THE VICTORIAN AGE.

IT was a happy idea of Messrs. Elliott & Fry to mark the opening of their new premises at 63, Baker Street, by arranging there an exhibition of photographic portraits of notable people of the Victorian age taken at the "Talbotype Galleries," which were established in 1863. The exhibition, which includes 151 portraits, is a pageant of Victorian genius and fame. One lingers with exceptional interest before the many striking likenesses of men and women who played a leading part in the politics, art, science, literature, commerce and society of the last century, to name only some of the spheres of human endeavour which are here represented. The catalogue usefully states the year in which the portrait was taken, and it is interesting to look upon the boyish exuberance of the late Lord Northcliffe (104) of 1896, and mentally to contrast the present features of Mr. Lloyd George (131) with those which were less familiar to the public in what are commonly termed the "Limehouse days" of the ex-Premier. In one instance two portraits, taken at an interval of twenty years, are shown of the same personage, Dr. Joseph Parker, the former minister of the City Temple, who, in 1871, wore Kruger-like whiskers, which gave a grotesque appearance to his solemn features. But almost every portrait is of a man or woman who was a leading personality in one sphere or another. Together on the walls are Huxley, Tyndall and Herbert Spencer; Longfellow and R. W. Emerson near to them; Millais and Leighton; Walter Besant, Matthew Arnold, Mark Twain and Spurgeon. The politicians are here in great force —Gladstone, Cobden, Lord Salisbury, Labouchere, Joseph Chamberlain, John Bright and Lord Randolph Churchill. The portraits of Gilbert and Sullivan hang alongside those of Sims Reeves, Grieg, Liszt and Pachman; and the Royalties form a considerable part of the exhibition and include Queen Victoria and the present King and Queen when, respectively, Duke of York and Princess Mary. The student of costume will derive as much pleasure from the exhibition as will those who visit it for its portraits of the great ones of the past The fashions of the late Victorian period are evidenced in the many portraits of society women, and a few additional prints are shown illustrating the styles of dress which characterised the 'seventies of the last century. There must be very few people indeed who cannot find an hour's genuine enjoyment in visiting this exhibition, which is open free from 10 a.m. to 5 p.m. daily for some time to come.

We were particularly interested in inspecting privately an autograph album, kept by the late Mr. J. J. Elliott, in which had been inscribed the signatures of his innumerable sitters of note, accompanied in many instances with passages from their writings or some words of friendly greeting, also in the sitter's own hand. The volume forms a priceless souvenir of the history of the business, and must be a possession which is unique in the experience of photographers. But then it must be remembered that in the 'sixties and 'seventies of the last century Messrs. Elliott & Fry's premises were the rendezvous of many artistic and literary celebrities, and it was here that Charles Keene drew many of his "Punch" cartoons

Of Messrs. Elliott & Fry's new premises we hope to have an opportunity of writing at greater length at an early date, when photographs are available. No. 63, Baker Street, is next door to the house in which for sixty years the business of Elliott & Fry has been carried on. In fact, for the purpose of facilitating removal, a breach was made in the dividing wall, and much of the apparatus and stock conveyed by this route. The premises are unique among London photographic studios by their large dimensions and by the fact that all the apartments which the public enter are upon the ground floor. There are three large studios, numerous dressing rooms and business offices, in addition to three spacious exhibition galleries. It is the intention of Mr. Beaufort, the present head of the business, to set aside one of these for periodical exhibitions of the work of painters, etchers, or draughtsmen. The basement portion of the premises accommodates the numerous workrooms and the firm's stock of negatives, numbering upwards of two million. In addition, the basement accommodates the installation of the Photogravure Company, of which Messrs. Elliott & Fry are proprietors, and which is engaged in the production of photogravure reproduction of portraits. Even these claims upon the space of the lower part of the premises leave much room still vacant for the expansion of the business and for the addition of other branches, to which we will refer more particularly when writing of the premises from the photographer's standpoint. Here we must content ourselves with paying a tribute to the success with which Mr. J. W. Beaufort has advanced a business which has always been an institution in photography and which, under his continued direction, promises to eclipse its previous history.

FORTHCOMING EXHIBITIONS.

December 9 to 31.—Rochdale Amateur Photographic Society. Particulars from the Hon. Secretary, W. Lord, 10, Derwent Street, Rochdale.

1923.

February 5 to March 3.—Northern Photographic Exhibition, City Art Gallery, Manchester. Latest date for entries, January 12. Particulars from the Hon. Exhibition Secretary, Walter Johnson, 30, Hartington Road, Chorlton-cum-Hardy, Manchester.

February 10 to 24.—Scottish Photographic Salon. Particulars from the Secretary, George A. Ross, Northfield Cottage, Brechin.

March 1 to 8.—Birmingham Photographic Society. Latest date for entries, February 15. Particulars from the Hon. Secretary, J. E. Breeze, 178, Broad Street, Birmingham.

March 2 to 31.—Pittsburgh Salon of Photography. Latest date, February 5. Secretary, Charles K. Archer, 1,412 Carnegie Building, Pittsburgh, Pa., U.S.A.

March 13 to 16.—Exeter and West of England Photographic Exhibition. Particulars from the Hon. Secretary, R. W. J. Norton, 4, Buddle Park, St. Thomas, Exeter.

March 15 to 24.—Photographic Fair, Holland Park Hall. Secretary, Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

AIRMAN KILLED WHILE PHOTOGRAPHING.—An attempt to "shoot down" another aeroplane in mock combat was said at the inquest last week to have caused the death of Flight-Officer William James Gayes while flying at Warden, Kent. Gayes was using a "camera-gun," which, when the trigger is pressed, instead of firing a bullet, photographs the object at which it is aimed, and shows if the shot would have struck. The theory was advanced that, after diving 2,000 ft., he kept the nose of his machine depressed too long, and struck the tail of the other aeroplane. A verdict of accidental death was returned.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications November 27 to December 2 :—

NEGATIVES.—No. 32,988. Production of photographic negatives. A. G. Clark.

CAMERAS.—No. 32,937. Photographic cameras. J. A. Leemann.

APPARATUS.—No. 32,884. Gyroscopic stabilisation of cameras, etc. Sir J. B. Henderson.

APPARATUS.—No. 32,820. Photographic apparatus for use with roll-films. A. Huber and W. Simons

APPARATUS.—No. 32,938. Apparatus for projecting and viewing colour photographs. J. A. Leemann.

X-RAY PHOTOGRAPHS.—No. 32,850. Taking Röntgen pictures for medical, etc., purposes. J. F. Freund

CINEMATOGRAPHY.—No. 32,599. Treatment of cinematograph, etc., films. W. C. Jeapes.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

SINGLE PICTURE STEREOSCOPIC CAMERAS.—No. 188,093. (August 13, 1921.)—The invention provides two pairs of prisms for each lens, the separate prisms of each pair being mounted on axes arranged at right angles to the path of the rays of light whilst each of the prisms is capable of being turned separately and independently on its axis. An anastigmatic lens is arranged in front of the film, this lens being adjusted independently of the prisms. The prism, which is disposed between the lens and the pairs of prisms for conducting the rays of light along convergent lines to a focus on the film, is adjustable for focussing the camera. The camera casing of the improved construction is shown at 1 having projecting mountings 2 for lenses 3. The irises 4 are arranged for dependent opening and closing by connecting their operating arms 5 to a rod 6.

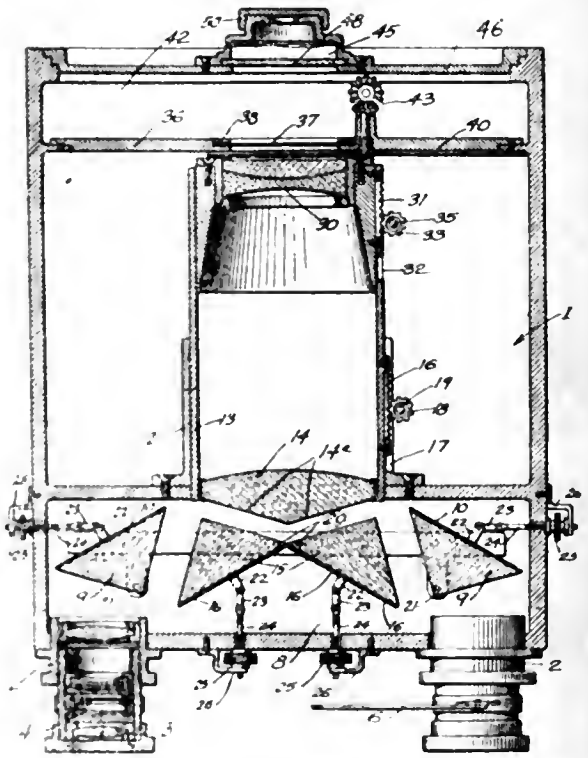
The lenses are in the same horizontal plane and are transversely spaced and arranged to focus upon a common object. The light passing through the lens structures enters a transverse chamber 8 within the camera casing, and prisms 9 are arranged within chamber 8 in alignment with the respective lens structures. The prisms are provided with reflecting backings 10 and bend the rays of light projected through the respective lens structures toward one another.

A guideway 12 extends from chamber 8 midway between prisms 9, and a mounting 13 carrying a prism 14, slides in this guideway. Prisms 15 are arranged in chamber 8 between each of the prisms 9 and the prism 14, and are formed with reflecting backings 16 and so arranged that the rays of light from the respective prisms 9 will be bent toward the prism 14. The prism 14 is provided with angular surfaces 14a at the side toward chamber 8, and against which the rays of light from the respective prisms 15 are received. The prism 14 is so arranged as to bend the respective sets of rays of light, and these, projected along convergent lines beyond prism 14 and through the mounting 13, come to a focus on a film 37 after passing through a lens 30.

The prism mounting 13 is adjustable in guideway 12 in order to position prism 14 properly. This adjustment may be accomplished by means of a rack 16 upon the mounting 13, and projecting through a slot 17 in the guideway 12. The rack is engaged by a gear 18 upon an actuating shaft 19, which may be provided with a suitable head. The prisms 9 and 15 are pivotally mounted upon rods 20, through bearings 21 in chamber 8, and the pivotal mountings for the prisms are so arranged that the latter may be relatively adjusted in order to bend the rays of light from the lens structures through prisms 9, and thence through prisms 15, so as to be finally projected against the respective surfaces 14a of the prism 14.

Hand operated means are provided for independently adjusting prisms 9 and 15, and for this purpose arms 22 extend beyond the reflecting backings of the prisms and are connected by links 23 to screw rods 24, through openings in the camera casing and provided with nuts 25, which are held in position by means of brackets 26. At the rear end of mounting 13 through which the two sets of rays of light are projected along common lines, an anastigmatic lens 30 is provided, the lens structure being slidable within mounting 13. This lens structure may be adjusted by means of a rack 31 extending through a slot 32 in the mounting 13, and having a gear 33 engaging the rack. The gear is mounted upon a shaft 35, which is provided with a head.

Beyond the lens structure a transverse partition 36 is arranged, and a film strip 37 is adapted to move past an opening 38, which is in alignment with the lens structure 30 in order that the rays of light projected through the latter will be received against the film strip. When the camera is employed for motion pictures,



the film strip is moved by the usual mechanism, and the shutter 40 is mounted in partition 36, so that in rotation it will pass between the lens structure 30 and the film strip 37. When such a shutter is mounted in the camera, a space 42 is provided in the camera casing in rear of partition 36, and the usual driving connection 43 is arranged in this space and extends beyond the camera casing.

A sight opening 45 is provided in the camera casing in the rear wall 46, beyond the film strip 37. The sight opening carries a ground glass 48 so that before the film is in the camera, or when the same is drawn aside from opening 38, an image will be formed upon the ground glass which may be observed through the sight opening for the purpose of setting the camera in the required direction for photographing the object. The sight opening may be closed by a cap 50, when the camera is in use.—Dr John Carl Wichmann, 115, Frazer Avenue, Ocean Park, Los Angeles, California, U.S.A.

The following complete specifications are open to public inspection before acceptance :—

LIGHT SENSITIVE COATING.—No. 189,433. Light sensitive coating. Wadsworth Watch Case Co.

CAMERAS. Nos. 189,438 and 189,439. Folding photographic cameras. Baille Lemaire et Fils.

FOCUSSING DEVICES. No. 189,440. Focussing devices for photographic cameras. Baille Lemaire et Fils.

FILMS.—No. 189,444. Treatment of photographic films and apparatus therefor. Counsell Film Process & Chemical Co., Ltd.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

SEPTON.—No. 430,290. Photographic chemicals, photographic plates and photographic films (sensitised). Johnson & Sons, Manufacturing Chemists, Ltd., 23, Cross Street, Finsbury, London, E.C.2, chemical manufacturers. October 7, 1922.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register :—

THE KEY TO SUCCESS (BULLDOG-WORLD DESIGN).—No. B425,574. Photographic papers. Kappa Works, Ltd., Mogden Lane, Isleworth, Middlesex, baryters and manufacturers of photographic papers.

VELOPHOT.—No. 427,299 Photographic apparatus included in class 8. "Velophot" Erzeugung und Vertrieb Photographischer Neuheiten Gesellschaft mit Beschränkter Haftung, Concordiaplatz 4, Vienna 1, Austria.

New Books.

Discoveries and Inventions of the Twentieth Century. By Edward Cressy. London: Routledge. 12s. 6d. net.

MOST of the chapter headings of this handsome book of 460 pages mark the development of invention in the last century. Steam power, electric lighting and furnaces, railways, steamships, coal gas, motors, cold storage—these are among the triumphs of the inventor which revolutionised the habits of the civilised world during the Victorian age. Nevertheless Mr. Cressy justifies his title, for he has seldom had to cross his frontier line of 1900 for the rich material which forms his story of what the engineer, the chemist and the electrician have done during recent years. His crowded and well-written pages show the immense activity in the great branches of industry during the past twenty years, and not industrial inventions only, but scientific discoveries such as those of the physical chemist, which are changing our view of matter. For the most part his subject lies in the commercial sphere, manufacture, engineering, aerial transport and wireless telegraphy, modern agriculture and the revival of water-power, in addition to the subjects we have already named. His chapter on photography briefly glances over colour processes (where he goes astray on a minor point by including the Warner-Powrie among "commercial" colour plates), cinematography, and the use of cinematographic and other photographic methods in the analysis of the travel of projectiles Photographers, perhaps, will find more of fresh interest to them in the very excellent descriptions of the most modern patterns of electric lamps, arc, incandescent, and mercury-vapour. The book is indeed an admirable non-technical account of the chief industrial developments of the present century, described in a way to make it of value to adult students and also of interest to boys, for whom it makes a most commendable gift.

The American Annual of Photography, 1923. Edited by Percy Y. How. New York: George Murphy. 1.75 dollars.

THE 1923 volume of the "American Annual" leads off with a new feature, and a very good one, in the shape of a review of photographic progress during 1922. This is written by Carroll B. Neblette, who, within strict limits of space, provides an exceedingly useful résumé of the original work which has been done in sensitometry, colour sensitising and desensitising, emulsion grain, developers and development and printing processes. Mr. Neblette commendably gives references to the original places of publication of the papers and articles which he summarises. His contribution thus gives a more permanent value to the "Annual," the literary contents of which has usually been of a somewhat ephemeral kind, if we may use that description without offence to those who have made its pages the vehicle for their various experiences in photographic processes. Their articles are not by any means to be despised, yet the publication needed some more extensive survey, and it is precisely this which Mr. Neblette has provided. Notable among the practical articles are several on Carbro, including one by A. C. Braham. Bromoil difficulties occupy one contributor; H. F. Raes gives formulæ for extra-rapid fixing baths, by use of ammonium chloride; Dr. M. G. Lovelace describes his practical experience of desensitising with phenosafranine; A. Krug recommends addition of alcohol to the sepia toning bleach, and amateurs with little accommodation for their work will be interested in the photographs and specification of a kitchen cabinet for holding photographic requisities and convertible into a work bench for developing and printing. A selection of the formulæ for developers, toning solutions, etc., current in American practice, occupies the final pages of the book, together with tables of weights and measures, diaphragm numbers, and a directory of photographic societies in the United States. The text is lightened by a great many reproductions of photographs aiming at pictorial quality. Many of these no doubt provide incentives to the beginner, but we cannot help thinking that, in the selection of works for reproduction, better use could be made of the excellent paper and printing which characterise the volume as a whole. The book is issued also in a cloth edition, price 2 dollars 50, and is obtainable from Messrs. George Murphy, 57, East Ninth Street, New York.

New Materials.

Septon Sepia Toner. Made by Johnson & Sons, Cross Street, London, E.C.2.

THIS new sepia toning solution, which has just been put upon the market by Messrs. Johnson, provides an alternative to the old methods of toning bromide and gaslight papers, while very much simplifying the process. By one simple operation the black silver image is changed to a rich brown or cool sepia, the colour depending upon the make of bromide or gaslight paper. It is found in practice that gaslight papers tone to a richer colour than bromides. The solution, which is sold in 1-oz. bottles, is very concentrated, each bottle making 1½ gallons of toning solution. For use, 10 minims of the concentrated solution are added to 5 ozs. of water, which should be at about 75 deg. F. The dry print is immersed in the solution at this temperature. Toning takes place at a moderate speed; we find that a good cool sepia tone is produced in about 10 minutes.

The solution deposits a very fine yellowish-white precipitate, but this does not seem to affect the toning properties of the solution. No appreciable reduction of depth in the printed image is noticed beyond the fact that the colour is changed from black to a slightly warmer one, and photographers who are in the habit of using a hypo-alum bath which has been correctly ripened, need make no difference in the depth of their bromide or gaslight prints. The solution appears to be some sulphur compound, as it has a slight odour of sulphuretted hydrogen, but this is in no way objectionable and does not at any time during its use approximate the usual intensity of a solution of sodium sulphide.

It is suggested by the makers that toning should be carried to completion in the solution, since if the prints are removed before this stage is reached, toning proceeds in washing and drying until the final result is complete reduction of the black silver to the warmer-toned product. But as different makes of paper tone to different degrees of sepia, it may be easily found by experiment which paper gives the tone desired. One make of bromide paper which we have used in this toning bath gave a fine cool sepia colour in 10 minutes at 75 deg. F., while another make of paper gave, under the same conditions, a very pleasing warm black tone. We feel certain that the "Septon" toner will be welcomed by photographers, as it at once does away with the usual messy and strongly-smelling processes, while giving tones equally as pleasing and in every way as permanent. The solution is put up in 1-oz. bottles, neatly packed in cartons, together with full directions for use, price 1s. 4d. net, or in half-pint bottles 6s. net.

SEEING BY WIRE.—A Reuter telegram from Paris says that M. Edouard Belin, the inventor of phototelegraphy, introduced on December 6 a process of seeing by wire, a process in which there may be photographic opportunities. He demonstrated the possibilities of seeing at long distance by means of a telephone wire. His invention, he explained, is based on the unique property of selenium of varying its resistance to electric current according to the degree of light to which it is exposed.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Monday, December 18.

Birmingham Phot. Art Club. "A Cycle Tour in the Wye Valley." J. O. Wilkes.
Bradford P.S. Members' Demonstration and Lecturette Night.
Derby P.S. "How I Make My Lantern Slides." J. Shaw.
Dewsbury P.S. "Amateur Photographer and Photography" Prize Slides.
Forest Hill and Sydenham P.S. "Ramble Round Dorking" A. H. Redman.
Glasgow and West of Scotland Amateur Photographic Association. "A Bird Lover with a Camera." G. W. McAllister.
Kidderminster and District P.S. "A Trip to Paris." A. Brooker
Southampton C.C. Judging the "Skyscape" and "Grey's Elegy" Competitions.

ROYAL PHOTOGRAPHIC SOCIETY

Meeting held Tuesday, December 12. Mr. E. W. Mellor in the chair.

The meeting was under the control of the scientific and technical group, and two papers were read. The first, by Mr. A. S. Newman, described the N.S. Cinematograph Camera and an electric drive. Mr. Newman said he had long made a study of the theories of inertia and momentum, and he decided, when constructing his camera for cinematography, to put these studies to practical use. In cameras of this kind it was well known that a film had to be moved from a still position and stopped again so that a picture could be taken. The two effects had thus to take place in a very short space of time; for instance, in the camera in 1/30th of a second, and in the projector in 1/100th of a second. The earliest cinematograph cameras were made to take only 75 feet of film, while the present-day type would take 400 feet. The difficulties of the camera man were very great, and the lecturer felt that anything that could be done to lessen the number of items that each operator had to think about, and probably do, would be a move in the right direction, and would lead to the making of better pictures. Pictures often had to be taken against time and with a fussy producer, nervous actors and indifferent electricians. Cinematograph camera operating was a nerve-racking job.

The essentials of a perfect camera are that it should be practical, reliable and automatic. It should be light in weight, small in size, and particularly not liable to warp or change under varying conditions of heat or cold. The camera should also be easy to drive, focus and adjust, while freedom from vibration was of great importance. Indicator scales should be in a convenient position and easily read, while it should also be possible to change from one lens to another in the shortest possible time.

All these points had been embodied in the "N.S." Cinematograph Camera, and the fact that this apparatus had been used upon the Mount Everest expedition, under the most trying of conditions, spoke volumes for its efficacy. The body and all the non-wearing parts of the camera were made of Duralumin, a combination of aluminium and zinc, which was not affected by sea air. All parts were machined from the wrought, no castings being used. A special feature of the fitments of the camera was the indicators for iris of lens, focus and film measurement, all of which were located on the back wall of the box. It was quite possible to tell from the film indicator exactly which picture area of film was actually being exposed, and this out of a length of 400 feet. The fade mechanism of this apparatus, so important nowadays, was made to work in either 5 feet or 10 feet, while fading in or fading out could be obtained.

For focussing a reflex mirror with tubular eyepiece was provided. This fitting was attached by means of a slotted groove to the side of the camera, and when the mirror was in position the film-changing gear was locked. This prevented many feet of film being wasted. The mirror was of speculum metal, reflecting approximately 85 per cent. of the incident light, and was found of great durability. Different eyepieces were provided, one reaching to the back of the camera, and using a double reflex system allowed the camera to be placed in any position and focussing to be effected with considerable ease.

An interesting feature of the camera was the cam adjustment of focussing and stopping down the lens. Two gears were provided for lenses of different focus, yet the scales engraved on the camera back would suit each lens. The film was moved forward by a claw movement, an improvement upon a system invented by the lecturer in his school days. This movement was particularly clean and reliable, and one claw only was used. The gate pressure, used in most cameras to stop the film, was in this case particularly light, it only being necessary for this fitting to flatten the film while the exposure was being made. The threading-up of the film, always a difficult job, had been much simplified in the "N.S." camera, a special hardened brass carrier of intricate design being used.

The motor drive for the camera, described by the lecturer as the operator's third hand, consisted of a small specially designed 8-volt motor, which was attached by simply sliding it into a slot. The gear of the motor then engaged the gear of the camera, and upon connecting up with the source of electricity the camera could be worked at any desired speed. A control box, which allowed the operator to be some distance from the camera and to know, by means of a delicate galvanometer, if the motor was working correctly, was shown, and the camera was driven from some 60 feet distance by simply pressing a button. This was of great use to travellers and explorers, who would probably have to place the camera in a dangerous position while themselves seeking protection in a neighbouring tree. Upon the proposition of the Chairman a very hearty vote of thanks was accorded to Mr. Newman for his able lecture and demonstration.

The second paper, "The Factors Which Govern Gamma Infinity," by Messrs. G. I. Higson and F. C. Toy, was then read by Mr. Toy. Much experimental work had been done, and was still progressing upon this elusive property. The points which effect the maximum density of a plate were fully discussed. The larger grain of silver halide was more sensitive than the small, while it gave greater

density upon development. Developers themeslves changed the figures obtained, hydroquinone giving a higher gamma than metol.

The gamma figure of a plate could be roughly determined by microscopic examination of the unexposed silver emulsion. Small grains, very uniform, were found to give a high gamma of 3.5 to 4, and even upwards; large grains, uneven in size, a gamma of from zero to 1.5, while two intermediate cases of large uniform grains and small uneven grains gave a figure of 1.5 to 3.5.

In the discussion which followed, Mr. Olaf Bloch exhibited micro-photographs of an emulsion he had prepared and which had afterwards been physically effected. The grain of silver halide was of equal size in both emulsions, yet one had an H. & D. figure of 9 while the physically treated emulsion had a figure of H. & D. 178.

A vote of thanks to the authors of the paper, and also to Mr. Toy for his reading, was proposed by Mr. Olaf Bloch and heartily approved by the audience.

CROYDON CAMERA CLUB.

A lantern-lecture on the "Passion Play" at Oberammergau was given by Mr. F. Ackroyd, who dealt with his subject in very tactful way. For once the ever-prevailing spirit of levity in the club was stilled, and all listened with attention and interest to his graphic account of this wonderful representation of the great sacred drama. Very clearly he conveyed the traditional earnestness and high ideals that inspire the performers, who are mostly peasants and wood-carvers.

The absence of any commercial spirit, he continued, was notable. A huge sum was offered for the right to film the play, and a tempting bid was made for the transfer of the company to give performances in the U.S.A., but both offers were declined.

The "Passion Play," he said, originated in the middle of the 17th century, and is given every ten years from May till September. It suffered interdict at times, and interruption during the Great War. A hearty vote of thanks was accorded Mr. Ackroyd.

EDINBURGH SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.

Meeting held December 4. Present:—Mrs. Mackay, Miss Bertram, Miss Grace D'Arcy, Mr. J. Campbell Harper, Mr. J. B. Johnston, Mr. George Balmain, Mr. George Aikman, Mr. William Fergusson, Mr. Norman Thomson, Mr. E. D. Young, Mr. John Thomson, Mr. A. J. Hughes, Mr. Swan Watson, Mr. Yerbury, Mr. George Ayton, Mr. John C. Bambrick, and Mr. W. J. Hutcheson. Mr. J. Campbell Harper, president, in the chair.

The meeting discussed the desirability of holding an exhibition of photography in Edinburgh. It was felt that an exhibition would be sure to give a great stimulus to photographers in Scotland, and lead to a revival of business. Mr. Young, seconded by Mr. Yerbury, accordingly moved that an exhibition be held for two weeks, from March 19, 1923, in the Hall of the Society of Eight, Shandwick Place, and this was unanimously agreed to. The secretary was instructed to secure the hall at a rent of £15 per week, which sum would include the cost of lighting, heating and attendance of the caretaker. The following committee were chosen to carry out the arrangements:—Mr. J. B. Johnston, Mr. E. D. Young, Mr. Yerbury, Mr. George Ayton, and the president. The meeting, after considering the subject, made the following specific recommendations:—That all spaces are to be balloted for; that the spaces should be of equal size, and no exhibitor have more than one space; that the floor line be restricted to 2 ft. 6 in. and the height to 5 ft. 6 in.; that the exhibits be glazed, and that passe-partout or wooden frames, not exceeding ½ in. in breadth, be used. With these recommendations, the committee were given full powers to carry through the arrangements. It was agreed that notification should be sent to each exhibitor of the space allotted to him, and a request for payment of £3 3s. towards the expenses in connection with the exhibition.

The meeting agreed to hold an assistants' social evening, with whist drive and dance, on Monday, February 5, 1923, and afterwards considered the estimates submitted by the committee. Mr. George Balmain, Mr. Norman Thomson and Mr. Fergusson were appointed a committee for carrying out the arrangements, and Mr. Bambrick was co-opted as a member of this committee to arrange a musical programme for the evening. It was agreed that the masters should pay for each assistant, the other expenditure to be paid out of the Society's funds. It was arranged that each member should communicate with the secretary the names and addresses of each assistant in his employment, so that formal invitations could be sent to them direct.

Commercial & Legal Intelligence.

NEW COMPANIES.

JONES (BECKENHAM), LTD.—This private company was registered on December 6 with a capital of £500, in £1 shares. Objects: To acquire the business carried on at 5, Rectory Road, Beckenham, and to carry on the business of opticians, dealers in photographic supplies, etc. The first directors are: W. Ault, 58, Glenalmond Road, Sheffield; S. E. White, Peasedown St. John, near Bath. Qualification: 1 share. Registered office: 5, Rectory Road, Beckenham.

CRANE, PAGET & CO., LTD.—This private company was registered on December 6 with a capital of £3,000, in £1 shares (500 "A" preference, 2,000 "B" preference, and 500 ordinary). Objects: To carry on the business of photographers, etc. The permanent directors are: L. Teller, 161, West End Lane, Hampstead, N.W.: M. E. Balcon, 15, Sutherland Avenue, W.9. Qualification: £10. Remuneration: £300 per annum, divided between them. Secretary: J. Freedman. Registered office: 17, Cork Street, Burlington Gardens, W.

GEORGE ODELL, LTD.—This private company was registered on December 5 with a capital of £3,000, in £1 shares. Objects: To acquire the business of an optician carried on by G. Odell, of 31, King Street, St. James's, S.W., and to carry on the same and the business of dealers in photographic and mathematical instruments, etc. The first directors are: G. H. Odell, The Primrose Club, Park Place, St. James' Street, S.W., ophthalmic optician; A. H. Odell, 15, Dames Road, Forest Gate, E., ophthalmic optician's assistant Qualification: 1 share. Registered office: 31, King Street, St. James's, S.W.

News and Notes.

PATENTEES' COURT OF ARBITRATION.—The Institute of Patentees have set up a Court of Arbitration, to which disputes between inventors, patentees and manufacturers may be referred.

NORTHERN PHOTOGRAPHIC FEDERATION.—The twenty-first annual meeting was held in Newcastle on December 6. There was a large attendance of delegates. The annual reports showed that the Federation was in a strong position. Six new societies had joined during the past year, the number of societies now federated being 23. The list of lecturers and demonstrators showed a considerable increase. The present list contained 30 lecturers and 47 subjects. It was decided to re-issue the Federation year book, which will provide a valuable guide to camera users in the North. Mr. T. Spark, of Bishop Auckland, was appointed editor. It was also decided to hold an outdoor meeting in Durham during next summer.

On the election of officers, a letter was read from Mr. Wm. Milburn, of Sunderland, resigning the position of President, which he had held for the last 12 years, and thanking all for the support which they had given him during his term of office. On a motion from Mr. B. Redford, it was unanimously agreed that Mr. Robert Chalmers, honorary secretary for the past ten years, be elected to the position of President. Mr. J. W. Addison, another prominent Sunderland worker, was elected honorary secretary. The following officers were also elected:—Chairman, Mr. T. Spark (Bishop Auckland); Treasurer, Mr. Robert Simpson (Stanley); Competitions Secretary, Miss A. C. Flagg (South Shields); Travelling Exhibition Secretary, Mr. H. Burgess (South Shields).

GLASGOW AND WEST OF SCOTLAND SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.—On the evening of Wednesday, December 6, 1922,

a whist-drive was held by the members of this Society in Miss Rombach's Rooms, Hope Street, Glasgow, when a large company assembled. Progressive whist was engaged in, and, after refreshments had been served, a musical programme was provided by the committee having charge of the function. The evening was greatly enjoyed by all. A syllabus has been issued by the Society for the session 1922-23. This will serve the members as a ready reminder of the various meetings during the winter. We observe from the syllabus that representatives from Kodak, Ltd., have already this year delivered lectures to the Society on "Spot Lighting, Diffusion Discs, etc," and on "Printing Papers," and Mr. S. J. G. Chipperfield, of Vernon & Sons, advertising contractors, on "Publicity in Photography." Other items in the syllabus include a lecture by Mr. C. Pollard Crowther, F.R.P.S., of London, on "The Making of Portraits," a visit to the Glasgow Art Galleries under the guidance of the Curator, Mr. T. C. F. Brotchie, F.S.A. (Scot.), a whist drive, smoking concert, outing, etc. The Society appears to be having an active career, and it is to be hoped that the efforts of the committee and members, in addition to making for sociability and good feeling amongst them, will be helpful to business.

International Salon of the Pictorial Photographers of America.—For many years there has been a demand for a representative photographic salon in New York—a demand logical, not merely from the location and size of the city, but also on account of its importance as an art and photographic centre, and as a magnet for country-wide visitors in search of what is newest and best. With the institution of the Art Centre, and through its generous co-operation as a whole, the Pictorial Photographers of America, one of the founding and component organisations of that body, are enabled to announce an International Salon, to be held at the Galleries of the Art Centre, 65, East 56th Street, New York City, throughout the month of May, 1923. These Galleries are convenient of access, and are located in what has come to be the artistic nucleus of the city, and furnish ample, suitable, well-lighted space for an exhibition, if the entries warrant, of several hundred prints. Every effort will be made to secure representative foreign photography, as well as a collection of the best American work. In view of the importance which naturally attaches to this event, and which we shall aim in every way to signalise, we urge the early and earnest co-operation of all pictorial workers throughout the world. The jury of selection will be announced in advance of the exhibition. Consideration of all pictures will be deliberate and impartial. Acceptance will be restricted to work combining high artistic excellence with perfection of technique. Entry forms, with precise data, will be distributed at an early date. The chairman of the salon is Wm. A. Alcock, 44, Wall Street, New York City, and its secretary, C. W. Harting, 51, West 10th Street, New York City.

£3,000 Competition.—The second part of the competition in which prizes amounting altogether to £3,000 are being awarded by a group of manufacturers closed a week or two ago, and the entries, numbering over 15,000, were judged during the latter part of last week. At a luncheon held last Friday three of the judges, namely, Mr. Gordon Selfridge, Mr. W. L. F. Wastell and Mr. George Robey, were present to meet representatives of the manufacturing firms and of the Press. Mr. E. W. Houghton, in a short speech, said that the organisers had been exceedingly pleased with the standard of work which the entries represented, and it was evident that the competition had accomplished a great deal to extend and strengthen the popularity of photography as a pastime. The following are the chief awards which were made, in addition to numerous consolation and other prizes:—Class 1.—1st, (£100), G. L. A. Blair, Paisley; 2nd, C. Ponting, Scarborough; 3rd, Fred H. Clift, Skegness; 4th, C. Cecil Davies, Portsmouth. Class 2.—1st (£100), J. Williams, Melbourne, Australia; 2nd, E. J. Mowlam, *H.M.S. Malaya;* 3rd, Mrs. B. R. Bryant, Workington; 4th, G. E. Flack, Cricklewood. Class 3.—1st (£100), J. S. Cooper, Newcastle-on-Tyne; 2nd, Mrs. A. Jewson, Nottingham; 3rd, J. M. Purdon, Dundee; 4th, Thomas Blyth, Glasgow. Class 4.—1st (£100 and gold medal), W. Findlay, Glasgow; 2nd, George F. Prior, Chingford; 3rd, R. Caudwell, Norwich; 4th, Blanche J. W. Mercer, Dublin. Class 5.—1st (£100 and bronze medal), H. Abbott, Junr., East Dulwich, London; 2nd (silver medal), P. C. Pell, Chesham Bois; 3rd, Herbert Felton, London, W.C.1; 4th, Stephen W. Shore, Finchley, London. Class 6.—1st (£100), H. W. Burnup, Newcastle-on-Tyne; 2nd, Alfred Field, Australia; 3rd William Brown, Motherwell; 4th, James Hay, Grangemouth. Class 7 (Juniors).—1st, G. Taylor, Hammersmith, London; 2nd, Josephine Manby, Leeds; 3rd, Ebenezer Clark, Motherwell; 4th, James L. Lawler, Ireland.

Correspondence.

*** *We do not undertake responsibility for the opinions expressed by our correspondents.*

ISLINGTON PHOTOGRAPHIC SOCIETY.

To the Editors.

Gentlemen,—The effort to form a photographic society for Islington has met with distinct success. An inaugural meeting will be held at Highbury High School, Highbury Grange, Highbury Barn, N.5, on Tuesday, December 19, at 8 p.m., where excellent accommodation has been provided (by the kindness of Dr. L. F. E. Johnson). All ladies and gentlemen are heartily invited, and M. Henry Vandelmans will show (for the first time in England) specimens of the new three-colour process, and pastel colour process of Dr. Sury.—Yours faithfully,

Leonard Balston.

30, Ashley Road, Crouch Hill, N.4.

THE MANIPULATION OF MATT PLATES.

To the Editors.

Gentlemen,—Matt dry plates are now very popular; they have many advantages, and have, I believe, come to stop. During the past year I have used some hundreds of them, and shall continue to use them.

I wonder if you or your readers can suggest—or recommend from experience—a remedy for the defect known as finger-nail markings. This defect is, of course, not the fault of the plate itself, but is due to carelessness of the worker. However carefully one may work, one sometimes digs the finger-nail into the film and makes a tear. Now, a finger nail marking on a matt plate is quite different from a similar marking on an ordinary gelatine plate, because, I suppose, of the structure of the matt emulsion.

When one nailmarks an ordinary gelatine plate, attempts are usually made to get the tear in its proper position, overlapping or not, according to the skill of the worker and the method employed. In any case, the torn film usually dries quite all right, and the retoucher can put the matter right on the negative or print, and often no sign of tear is visible.

Matt plates, however, call for a different treatment, because of the film differing in some way from ordinary gelatine. When attempts are made to get a nail-torn matt film back in position it will be found not to "work" so easily as the usual gelatine coating. It is, however, useless in my hands, at any rate—to spend any time in coaxing the torn matt film back into position, for the simple reason that it will not attach itself to the glass and dry as ordinary gelatine will do. The torn piece, when dry, crumbles away, leaving a patch of bare glass, and one which is not filled up easily.

The obvious way out of the difficulty is, of course, to be careful and not nailmark matt plates, but accidents will happen, and an accident in the shape of a nailmarked matt film is far more serious than the uninitiated imagine it to be, hence my request for an infallible remedy.—Yours faithfully,

A. Beverley Thomas.

EASILY MADE ANNOUNCEMENT SLIDES.

To the Editors.

Gentlemen,—The following method for making announcement slides may be found quicker than the one recently mentioned by Mr. Reeves in your columns:—

Take an unfixed plate (preferably lantern) and write the wording with lead pencil, adding a little corner decoration if needed. Trace over this with a hot darning needle, using the blunt end. For convenience the needle may be placed in a retouching holder. Finally the plate should be fogged in strong light. Two needles may be used to save waiting, one being heated while the other is in use.—Yours faithfully,

Sydney Ashworth.

Hayhurst Street, Northwich,
December 11.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

E. M.—We are sorry that "Photopel" developers are quite unknown to us. So far as we can discover, they have not been advertised, and certainly we have never had any of this brand through our hands.

J. E. C.—We get our rubber stamps made for us by Messrs. E. M. Richford, Ltd., 8-9, Snow Hill, London, E.C.1, which is a very good firm. The Sanderson camera is made by Messrs. Houghtons, Ltd., 88-89, High Holborn, London, W.C.1.

H. A.—The lighting on the face is too hard, making the shadows very heavy. You require a reflector, or another lamp of lesser power, on the opposite side of your studio. Retouching to improve these heavy shadows is not to be recommended, the remedy being in the studio.

Roneo.—If you are contemplating entering the Process trade we have no doubt that you would be accepted as a student. You should write the Principal of the L.C.C. School of Photo-Engraving, Mr. A. J. Bull, M.Sc., at 6, Bolt Court, Fleet Street, E.C.4, and state fully your proposals.

W. S.—We have no means for analytically testing your sample of hypo, but from its appearance we should say it would be quite satisfactory. We have recently used hypo of a similar quality, appearing quite wet and of unusual crystalline structure, and found it, although we doubted its quality at first, to work quite well.

D. M.—(1) Dry mounting is now generally used, and would be most suitable for your purpose. (2) The Akron auxiliary press would suit you. This is a machine of light construction, but capable of taking your large mounts. The machine may be obtained from the Akron Manufacturing Co., 569, High Road, Tottenham, London, N.17.

A. V.—No, the lens is by another maker. It is, however, of good quality, and possesses a fair depth of focus. Lenses working at such a wide aperture as *f*/3 are certainly of use for portraits, but you must remember that the depth of focus is small, and allowance should be made for this in focussing and the arrangement of your sitter.

M. R.—Desensitising is now a practical process, and is used extensively in some of the larger studios where quantities of plates are required to be developed in the shortest possible time. Pinacryptol green is perhaps the most successful desentising agent. You could buy it from Messrs. Wallace Heaton & Co., 119, New Bond Street, London, W.

T. B.—On account of the great danger in mixing the constituent chemicals of a flash powder we will not take the responsibility of giving you a formula. From your description it is practically certain that the group was taken with one of the "Cirkut" cameras of Kodak, Ltd. A firm which undertakes the making of this kind of group is Panora, Ltd., 56, Eagle Street, London, W.C.1.

W. M. P.—You require oil-soluble aniline colours, both deep red and yellow, but we doubt if you will obtain a really good photographic ruby, as most of these types of aniline dyes pass some blue rays. The dyes may be obtained from Messrs. Stevenson & Howell, Ltd., 95a, Southwark Street, London, S.E.1. You could tint the varnish to a deep shade of orange-yellow by the addition of iodine, which may be obtained from any chemist.

M. M.—There is no preparation, as far as we know, which may be painted on electric lamp globes to render them sufficiently safe for use as dark-room illuminants. Most of the aniline colours when used in this manner pass also blue rays. A fitting which would be suitable, however, is the ruby globe and fitting, No. 64a, advertised by Messrs. Houghtons, Ltd., 88-89, High Holborn, London, W.C.1, some time ago. This is attached to the ordinary lamp holder over the electric bulb.

Flashlight.—It is best to develop your flashlight exposures in a dilute developer, say equal parts of the usual strength solution and water. This will give you a softer negative with full detail in the shadows. Your trouble is due in the first case to under-exposure. Use about twice the quantity of flash powder, and then develop your exposures as mentioned above. Yes, the "B.J." pyro-soda developer is very suitable for this class of work, but dilute it as we mention and you will get satisfactory negatives.

Enlarger.—We do not think you will be able to convert your horizontal enlarger into an upright pattern, and as you only require it for making postcards from the small films, we think it would be easier, as you suggest, to construct a printing-box enlarger for this purpose. In constructing this box you will want approximately 9 inches from the negative to the lens and 18 inches from the lens to the base board on which the postcard is placed. If the lens is in a focussing mount, you will be able to get a sharp image without much adjustment.

N. R. P.—The copyright is yours, and the making of the lantern slides is an infringement of your copyright. It is nothing to do with the publishers of the book, as you retained the copyright by the statement in your letter and their acknowledgment. It would have been better perhaps to have added the word copyright to your name under the illustrations. You should, however, get into communication with the producer of the slides and find out what he proposes to do; perhaps a payment to you would settle the matter.

Colour.—(1) The process is an old one, and we do not think the materials are obtainable now. (2) Tri-colour filters are obtainable from Messrs Ilford, Ltd., Ilford, London, E. (3) Apparently you have not allowed the bleached transparencies to remain in the dye bath long enough to absorb sufficient colour; six minutes is about the usual time (4) A book which would give you particulars of the colour processes you mention is "Practical Colour Photography," by E. J. Wall, obtainable from our publishers. Messrs. Henry Greenwood & Co., Ltd., 24, Wellington Street, Strand, London, W.C., price 13s. 3d., post free.

Brown Spots.—Your trouble appears to be due to the prints sticking together in the fixing bath It is as essential to keep the prints moving in this solution as in developing, but many workers do not give sufficient attention to this operation, especially when fairly large quantities of prints are being fixed. We should advise you to have the prints turned over and over, placing those at the bottom of the dish on top, and so reversing the position of all the prints one after the other during the whole time of fixing. An acid fixing bath should be used, and at no time should the prints be allowed to float on the surface of the solution and become partially surface dry.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3268. Vol. LXIX. FRIDAY, DECEMBER 22, 1922. Price Fourpence.

Contents.

SUMMARY.

Owing to the Christmas holidays the issue of the "British Journal" for December 29 closes for the Press to-day, December 22, as regards the editorial portion, and at the usual time on Wednesday next, December 27, as regards line advertisements.

In a leading article we endeavour to give a concrete definition of a practical kind of the kind of lighting which is described as "forty-five degrees," and proceed to show the usefulness of this example in the management of studio light, both natural and artificial. (P. 766.)

Mr. J. Effel, in the current instalment of his talks on studio portraiture, urges a livelier recognition of the artistic sense of the public, and protests against some of the time-honoured conventions which are observed in making portrait photographs. (P. 768.)

It is reported from Czecho-Slovakia that professional portrait photographers are allowed to follow their occupation only when they have been qualified by apprenticeship and by subsequent employment. (P. 765.)

The many directions in which a studio assistant can seek to become more highly qualified, are the subject of a contribution to "Assistants' Notes." (P. 772.)

In a recent lecture Professor A. P. Laurie mentioned the methods of cleaning oil-paintings, which might, perhaps, be regarded as the safest. (P. 778.)

In a contributed article Mr. W. Gard describes the running from accumulators of electric-light for the enlarging lantern. (P. 767.)

Dr. Lüppo-Cramer has devised a practicable process of making one negative from another at a single exposure by aid of a desensitising dye. The process is put forward as a demonstration of the oxidation theory of desensitising. (P. 765.)

In the current issue of the "American Annual of Photography," Mr. W. H. Zerbe describes a method of registration for multiple printing such as gum bichromate. (P. 771.)

Apropos of Mr. Tilney's review of his pictures of Westminster Abbey, Mr. Frederick H. Evans vigorously challenges the views there expressed or implied as to the essence of pictorialism. (P. 779.)

At the Royal Photographic Society, on Tuesday evening last, Mr. H. T. Meredith delivered a lecture in description of rotary photogravure as worked commercially. (P. 776.)

An exposure meter, which comes automatically into operation in accordance with the camera extension, is described in a recent patent. (P. 773.)

The Scientific and Technical Group of the Royal Photographic Society have completed the second volume of their bibliographical publication, "Photographic Abstracts." (P. 766.)

With next week's issue of the "British Journal" we hope to publish the annual index to these pages and to those of the "Colour Photography" Supplement. (P. 766.)

EX CATHEDRA.

Certificated Photographers

We hear from a correspondent that in the newly-organised Czecho-Slovakin Republic professional portrait photography is now a closed occupation, to be followed only by those whose qualifications have been officially recognised. We understand, although we have not the opportunity of confirming the information, that the qualification consists in serving a term of apprenticeship, followed by subsequent employment for a sufficient time in an approved establishment. Various suggestions have been put forward in this country in the past for applying a similar restriction, but no one, we think, has ever succeeded in devising a scheme which even approximately would deal in an equitable manner with the many grades and kinds of photography which are carried on as a livelihood. And in proportion as the processes of photography are simplified, and whilst the artistic taste of the public as a whole remains largely unformed, there is very little likelihood of the business of photographic portraiture becoming a close corporation like dentistry or even pharmaceutical chemistry. Strangely enough, it appears that in Czecho-Slovakia, or at any rate in its capital, Prague, there is an almost complete absence of co-operation between the members of this protected profession. Members of a privileged class are usually found to be drawn towards one another for the common protection of their interests, but it would seem that in this instance the sense of community is even less developed than it is among photographers in this country.

* * *

Desensitising and Duplicate Negatives.

By way of providing a practical demonstration of the correctness of his oxidation theory of desensitising, Dr. Lüppo-Cramer publishes in the current issue of "Photographische Rundschau" details of a process for making one negative from another by a single exposure upon a sensitive plate. A dry plate of fine grain, such as one coated with a lantern emulsion, is first given a general exposure to diffused artificial light for a time sufficient to yield a uniform medium density if the plate were to be developed. The plate, however, is next immersed for one and a half minutes in a solution consisting of 1 gm. of potass bromide dissolved in 100 c.c.s. of 1:5,000 solution of phenosafranine. Without subsequent washing, the plate which has been treated in this way is dried. It is then exposed under the negative for a time, averaging thirty to fifty times that which was given under similar conditions before treatment in the phenosafranine-bromide bath. It is then treated in any ordinary developer. After some practice, so it is stated, a perfect duplicate negative, though reversed as regards right and left, is obtained by this process. The chief element of success is a correct ratio of the two exposures to light.

Reproduced Negatives. The loss of quality so often noticed in reproduced negatives which have been made by contact printing for either the transparency or negative is frequently due to the fact that very little of the glass used as a support for the sensitive film is flat enough to allow of uniform contact being obtained between the surfaces, firstly, of the original negative and the transparency plate, and secondly, between the transparency and the plate which is to furnish the new negative. In the case of same-sized reproductions both these conditions may be present, but even with one there may be quite a serious loss of definition. Every experienced lantern-slide maker knows that even with a plate so small as 3¼ ins. square, the slides are much crisper if made through the lens than by contact. In making some enlarged negatives of subjects with very fine detail, we found it necessary to use a process printing frame with a ¾-in. glass front, and to apply the pressure by means of strong screws. This ensured contact, and neither negative nor plate was broken. Failing this, it is better to make both transparency and negative on film or through the camera.

* * *

The Annual Index. With next week's issue of the "British Journal" we hope to be able to include the index to the annual volume of these pages and to that of the "Colour Photography" Supplement. The compilation of these indexes is undertaken systematically, week by week, throughout the year, with the object of rendering the contents of the publications as accessible as possible to those who have occasion to make use of them. Nevertheless, we regret to find that evidently the indexes are not preserved, or at any rate not used, by many of those to whom they would be of great value. Over and over again it is our experience to receive questions which have been answered at much greater length than is individually possible in articles or notes which have been published in our pages within the preceding few months. Our publishers, also, are constantly asked to supply copies of past issues containing such and such an article, but usually without any indication of the date of the issue which is required. We endeavour to do our best for these various inquirers, but the help which we are asked to give them could be much more easily rendered were use made of the very comprehensive index which we prepare for the benefit of readers present and future. There are many, no doubt, unable to find shelf room for the bound volumes of publications such as the "British Journal," but a collection of the annual indexes occupies very little space. In our own study of other technical subjects, it is our custom to preserve such indexes of periodicals, the contents of which we may have need to consult from time to time.

* * *

Photographic Abstracts. Mention of the index to our own pages ought not to be made without a word of appreciation for the co-operative labour of the same kind which has been applied by the Scientific and Technical Group of the Royal Photographic Society to a much wider field. By examining practically all the periodicals which relate in one way or another to photography, and by making and publishing abridgments of papers and communications deserving of this treatment, Mr. B. V. Storr and his helpers have rendered a great service to the student or investigator who has need to learn of some item of fact or theory and also the place of its original publication. "Photographic Abstracts," in which this is done, has just completed its second volume, which itself is provided with a name index of many hundreds of entries, serving as a further clue to the identification of a piece of work if the name of the author is known. For the information of those who may not be familiar with "Photographic Abstracts," let it be said that it is issued quarterly by the Royal Photographic Society, 35, Russell Square, London, W.C.1, at the price of 10s. per annum, post free.

THE LIGHT AND ITS MASTER.

One of the most frequently recurring queries which we receive from our readers relates to the most desirable position for the main light of the studio, whether it be daylight or one of the many forms of artificial illuminants. Many of the inquiries which refer to artificial lighting come from photographers who have been working with daylight for years, and yet have not grasped the elementary principles of lighting to an extent which is sufficient to enable them to deal with an unfamiliar source of light.

The first point which has to be grasped by the beginner is, that within certain limits, one kind of light does not vary greatly from another, the difference between them being more in the way of intensity or strength and in concentration, rather than in an essential quality. There is no reason why any difference should be detected between a picture taken by daylight and one taken by any artificial light, even flash powder, provided that the light is skilfully controlled and a correct exposure given.

It has been accepted by practically all authorities on the subject of lighting the figure either for photography or painting, that the best starting point for the student is to commence with a light falling upon the head of the sitter at an angle of forty-five degrees. The light might, however, fall at this angle from many directions and would give as many different effects, so that it is necessary to explain in which way it should fall to produce a simple "three-quarter" light.

Given an ordinary rectangular apartment with top light or with a very high side light, the sitter is placed in front of the end wall, the whole of the glass being covered with blinds or curtains. A long rod, such as a billiard cue, has one end placed upon the sitter's forehead just over one eye, and then swung round so that it is at an angle of 45 degs. with the floor and also with the end wall of the studio. The free end of the rod will then be pointing towards the place at which light should be admitted to give the maximum of roundness in the picture. This gives the dominant light, which may be modified to obtain any desired effect, or to suit the physical peculiarities of the individual sitter.

Starting with an aperture, say, three feet square, it will probably be found that the lighting is fairly satisfactory but rather too vigorous for most tastes. It is therefore permissible to broaden it so as to give softer shadows, or to admit a lower side light to illuminate deep set eyes or to reduce the shadows in hollow cheeks. An old axiom of unknown authorship sums up the art of lighting in a few words. "Light from the sitter's end of the studio gives contrast (or brilliancy); light from the camera end gives softness." If this simple rule be borne in mind when in doubt as to arranging the blinds, the difficulty will at once vanish. If the blinds cannot be conveniently placed, the same effect can be produced by seating the model more or less under the darkened part of the roof.

As has already been remarked, such variations are necessitated by the differences between one sitter and another, but as a general principle the use of the 45-deg. light should be mastered, and other lightings will follow

almost automatically. It is important that the operator should feel that he is absolutely the master of his light, and this can only be done by starting with a small dominant light and broadening as necessary. The plan often seen of starting with a flood of lighting and shutting out what is deemed necessary, is a bad one for the beginner, for, as a rule, he will not shut out half enough.

With the knowledge thus gained the transition to artificial lighting presents no difficulties. The billiard cue will still serve to indicate the position of the dominant light, and the rest is a matter of diffusion and reflection. When a satisfactory negative has been obtained, the face being turned slightly away from the light, the operator should walk round his sitter to see how many different effects can be obtained without moving either light or sitter, the camera being moved into the proper position for each. The next step is to move the sitter so that stronger effects, "edge" lighting or Rembrandts, can be obtained. When the flash is the only possible light, the correct position for it can be found with the help of an assistant holding a lamp, which should be moved until the desired effect is obtained. A reflector will, of course, be necessary, and this also may be located by the aid of the lamp.

Points to be remembered in artificial lighting are: the nearer the light is to the sitter the harder the lighting and the shorter the exposure; a single concentrated light requires more diffusion, and consequently more exposure, than the same candle power made up by several lamps placed a little distance apart; reflectors should be placed where they will receive light; half-watt lamps do not retain their full efficiency right up to the time that the filament gives way; no direct light from the lamp or lamps is allowed to reach the lens, an efficient hood or curtain being necessary; and finally, the most rapid plates should be used.

Results, indistinguishable from each other, may be obtained with open or closed arcs, half-watts, incandescent gas, acetylene or even flash light, the only differences being those of length of exposure and convenience in working, so that the owner of any of these installations need not despair of success.

ACCUMULATOR LIGHTING FOR THE ENLARGING LANTERN.

The apparatus available for enlarging by artificial light has now reached a stage closely bordering upon perfection, but the actual illumination of such apparatus seems to have been somewhat neglected. After exhaustive tests of all the suggested systems, I have decided that electricity is the most reliable and effective. But the difficulty in this direction is that the power for such a light is not available to all workers, and consequently these have to use an illuminant often quite unsuitable. Another disadvantage which has deferred the use of electricity is undoubtedly the unsuitability of the ordinary lamp, the filament being too prominent and needing careful adjustment to prevent its design showing in the resulting print.

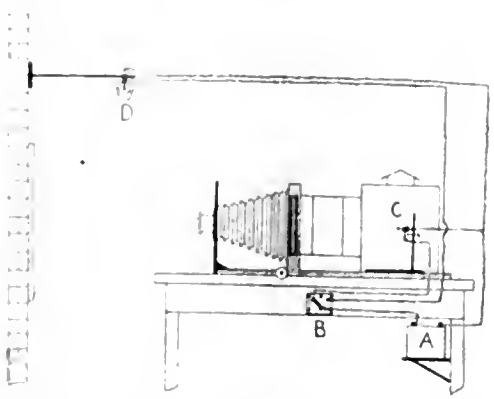
It is, of course, well known that the source of light in all apparatus of this kind should approximate as closely as possible to the smallest area of incandescence, a point of light being of greatest service and giving most even illumination. The electric arc answers these requirements, but this light is expensive to install and difficult to regulate, while it is limited to workers who have available an electricity supply. The Edison "Pointolite" lamp is also an excellent illuminant for the lantern, but this, again, requires great care in working. However, to those who use electricity the lamp may be recommended with every confidence.

It is, however, to those who have no electric supply that these notes are directed, the system suggested being both simple in use and easy and cheap to maintain.

The 4- or 6-volt metal filament lamp used in the head lamps of motor cars provides an excellent source of light; coming from what is practically a point, and of great brilliancy. The bulbs being perfectly round and "pipless," offer no obstruction to the light, while the lamps themselves are easily fitted in the lantern. The lamp may be run from an accumulator which is placed in some out-of-the-way position, and the dark-room may also be illuminated from the same supply.

For 4-in. to 5-in. condensers a 4-volt 4-watt lamp should be obtained, and also a 6-volt 60-ampere-hour accumulator. For 6-in. to 8-in. condensers a 6-volt 12-watt lamp is necessary, and the accumulator should be 8-volts 40-ampere-hours. For connecting up the lamp it is necessary to obtain first about 6 yards of thin electric light flexible wire or cord, as it is called of the size 35/40. Bell flexible wire, although thinner and cheaper, is not to be recommended, as the insulation is not so good as that used in the true lighting flexible.

My enlarger is arranged exactly as in the drawing; the easel is against the wall, and the apparatus itself stands upon a table. Over the easel and suspended from a bracket fixed to the wall is an 8-volt lamp D covered with orange paper. This allows plenty of light for fixing the bromide paper in position, and I find it much easier to use this light than to place a yellow cap on the lens. In the enlarger is a 6-volt 12-watt



lamp C fitted to a holder, which allows the light to be focussed and raised up or down. If the lamps are fitted with the bayonet cap system they may be attached to similar holders, but if screw caps are used it will be necessary to solder the leading wires to each pole of the lamp. For instance, the screw itself should have one wire soldered to it, and the metal tip to the other.

The slide holding the lamp is fitted to the rod of the lamp tray by means of the usual screw fitting, which in my case is a portion of a reflector originally intended for use with gas. A two-way switch is needed to allow either lamp to be switched on separately. It is not necessary for both lamps to be alight together, and a switch preventing this waste of current is quite necessary. The switch B is fitted to the side of the

table, and is quite out of the way. The connections to lamps and switch are shown in the diagram by the wavy lines, but the wires are shown as single ones. The cord used is of course double, but it will be easy to follow out the method of wiring and to cut the cord where necessary to make the connections.

It will be noticed that the lamp in the lantern is 6 volts, while the accumulator supplies 8 volts. Such a lamp being run on a heavier current will give an intensely bright light, but its life will consequently be shortened. As the light is only actually in use while the exposure is being made, it is found in practice that the lamp does not suffer to any great degree. The exposure with clean, fairly thin negatives, when enlarging to 10 × 8 or 12 × 10 from half-plate, is only a matter of a few seconds; usually I find 4 seconds quite sufficient.

The accumulator A, it will be noticed, is placed upon a shelf under the table, and in this position is quite out of the way, yet easily removed when it requires re-charging. It is strongly advised, when purchasing this part of the equipment, that only the best and most reliable make be obtained. Second-hand accumulators are to be avoided unless one is sure that they have not been damaged in any way by the previous owner. This is a point difficult to decide, and my advice is to leave them alone and buy a new one of well-known make.

The first charge should, if possible, be put in by the makers, but if this is impossible it should be handed over to a good firm of electricians, who make a specialty of accumulator charging. The first charge is of greatest importance to the life of the accumulator, and should be done with great care. When the accumulator is in use care should also be taken that it does not run down too far. If the light begins to appear dim, a new charge should immediately be put in. Most garages now charge accumulators for a few pence.

W. Gard.

WITH A PORTRAITIST IN THE STUDIO.

[In continuing his chapters on the essential things in photographic studio portraiture, Mr. J. Effel passes to consider some matters which he groups together as those of "criticism, character and convention." In doing so he takes exception to some of the rules which have often been taken as gospel, among them the dictum that the side of a sitter's face which should be photographed is the one which does not disclose irregularities or defects of feature.]

XI.—CRITICISM, CHARACTER AND CONVENTION.

Anyone who has acquaintance with stereoscopic photography will appreciate that portraiture by one lens tends to broaden the features; after all, we have to recognise that when we put upon paper a representation of a rounded object, we are actually reducing everything to the one plane. With sculpture there is no question of lighting, but the great problem for the photographer is to get the work to "stand out" sufficiently to convey the full story of the face. I maintain that the "too near the camera" objection is a sound one, based on the inability of the one-eyed camera to see round the sitter, and to give steep planes faithful rendering.

Generally speaking, it is in bust portraiture that this objection is so often met with. I would say, most decidedly, that with the average everyday work large heads are unpopular. Roughly speaking, well-educated persons may be taken "near the camera," with a greater chance of success than if our clients are lacking in culture, but the big head and figure are not popular. I find that I have quite got into the habit of sizing my portraits to indicate the height or build of the sitter, and in many cases to suggest the proportions wished for. Take a stout man who wants a three-quarter length. If you cut him off by the knees without any vignetting, he will most decidedly be "too near the camera." After reducing his avoirdupois by skilful posing and lighting, a figure slightly on the small size should be made with the help of intelligent vignetting. Women, and particularly stout women, dislike big figures, and it is worth notice that portraits of babies are frequently adversely criticised for being too big. Altogether the "too near the camera" is a fault which requires to be carefully thought about.

It is likely that if photography in natural colours suddenly took the place of our accustomed work, retouching would be largely a thing of the past, and it might also be true to say that there would be fewer problems in lighting. The camerists of a past generation, in the endeavour to put brightness and "colour" into their work, achieved only contrast and hardness as a rule. The later school—helped very greatly by the wonderful advances in the manufacture of photographic material—worked for "softness" and half-tones and fine detail. The ultra-modern portraitist now adds a little of the old school into the general working formula of the new by the addition of "pep" where wanted, by what is now well known as "spot light."

The Victorian photographer (I am referring to period, not to size of picture) favoured "plucky" results, and considered good contrast the popular taste; his successor (very frequently because his work was over-lighted and over-exposed) eschewed hardness, and thought the public should be educated up to *his* standard. Both were wrong, and the real fact of the matter is that little or no attempt was ever made to find out what class of picture would make the widest appeal, or to find the reason or reasons why photographers were suffering from lack of patronage.

The poor public have been sadly maligned. When I see the rubbish in art, in literature, in civic ideals, in philosophy, in education and culture, to say nothing of bad housing, rotten furniture, and adulterated food of a "popular" nature, I get something of a pain. As one who has been before the public in different *rôles*, I am firmly convinced of this fact that good work in any calling is the surest road to success. Yes, but that is just the problem for us, for what *is* good portrait photography? Emerson tells us that a man who makes better mouse traps than his fellows will soon do all the trade, but generalisations about portraiture are not so easy. It is soon settled if a mouse trap is a good one, but the same test cannot be applied to photographs, although I have heard that some pictures were fit to scare rats. There is unanimity of opinion that the trap which catches the most mice is the best, and there is never any preference for soft focus effects over sharp contact work. We are not such favoured individuals, however, as the mouse trap manufacturers, for it can truly be said of portrait photography that

> "Ten men love what I hate,
> Shun what I follow, slight what I receive,
> *Who shall arbitrate?*"

Surely, then, it is a matter of some difficulty to answer the question, "What is the popular taste in photographs?" Of course it is, but the difficulties are not insuperable, and, as usual with my somewhat original reasoning, we will best tackle the problem by first thinking of something else.

Let us give a few moments' consideration to what we call

"the public." An actor will tell us that the public won't take certain work; the comedian will assure us that his new song will bring the house down, and the practised orator will know the rhetorical tricks which get him *en rapport* with his audience, but I have no wish to let my readers into an Emersonian mouse trap, for in the cases I have mentioned the "public" must be regarded as a crowd or group, expressing a feeling common to them all at the psychological moment of appeal. We have also to remember that the politician, the actor or the lecturer moves within a very circumscribed area and draws to himself just that class who want exactly what he has to offer. The photographer, on the other hand, makes a purely personal appeal to individual taste or idiosyncracy, and where the stage artist gets his effect "across the footlights" in a second, the camerist's work is taken home, critically regarded, and judgment passed on it by quite a number of individuals or, as we might reasonably say, different people.

Fortunately, however, "most people are other people," and their artistic tastes may be gauged fairly accurately by considerations of class, of breeding, or of education. If I were working tin-types in Epping Forest *f*/32 would be my standard, while for Edinburgh highbrows, judicious fuzziness, or good, honest moves might be the right "atmosphere" in Auld Reekie.

But, after all, there are common denominators. Deep down in the heart of man is a love of colour and brightness. Let him be cursed with a bad liver or a spurious refinement, and he will shudder at the crudities of colour, visualising the world and its inhabitants in neutral tints, but Tolstoi's "unspoiled peasant" is a better judge of art values than most individuals who are credited with the possession of "culture." The child with his fondness for crimson lake and emerald green is wiser than we, and the pure colour of life is sicklied o'er with the Payne's grey of age. Most of us feel that we are doing wrong, for we all profess to love the sun while we burrow ourselves into cellar studios, drawing blinds across the face of God and blaspheming Nature with the feeblenesses of electricity. We talk about hygiene and fresh air, but all we mean is a draught in the dark-room where some poor ghoul spends his life. We play about and experiment with light, but most of our life is spent in shadow. We lead grey lives, we think grey thoughts and our very souls are grey. Something of this truth must have been perceived by the old albumen worker, for he "sunned down" or "tinted" his prints before toning, to soften his garish effects, and the "half-tone" artist must have felt that something was lacking, for, while shadow is the supremest thing in life, even the dreariest sitter turns sometime to the sun. And, Eureka! we have found that *spot light is an oasis in the Sahara of shadow.*

Having delivered myself of this purple passage, I will now put in a small stop and focus things a bit finer. What delights most the heart of a poor pioneer who has spent years in the wilderness putting both feet through backgrounds, skylights, systems and axioms is that the acceptance of "spot light" means the complete overthrow of the stultifying effects of dead-hand dictatorship.

In the main, poor or uneducated people like broad effects, vivid colouring and portraits that flatter. Ascending the scale of intelligence we will find a perception that if a thing is not white it need not necessarily be black, and a recognition that if Nature did not endow with beauty and regularity of feature, a faithful portraitist must tell the truth. Notwithstanding these points, and the fact that sitters frequently admire styles *for others* which they would not accept for themselves, I would say that a bright, clear photograph with the face well illuminated and in perfect focus, if anything a trifle "hard," and preferably looking to the front, considerably flattered in the retouching, and with the happiest expression that can be coaxed—that's a good enough working formula for everyday work. If to this technical quality you add a little of artistic feeling, cut out all the old stunts in backgrounds and posing (and vary the styles frequently) and hand to your client a finished print something different in tone, in texture or mount from the "usual thing" they have become tired of, all other things being equal, you ought not to lack customers. Beware of over-lighting and over-exposure. The dull, grey, unimaginative public need to be sparkled up a bit. A white dress may not look like a clean sheet of paper, but that is preferable to looking like a dull grey garment.

I am quite aware that in the foregoing paragraph I have said nothing that will make for a decided advance in what may be called real character portraiture. I sometimes think when photographic Jeremiahs lament the low standard of work in so many studios, and wish to "elevate" the humble fraternity (who, as a rule, do not want to be "teached") that they go the wrong way about improving our status. After all, everything is relative. Given a thousand literary men who could turn out epigrams and paradoxes from morning till night, then Max Beerbohm, Gilbert Chesterton and Bernard Shaw would be looking for the unemployment dole. Let all the dud portrait workers suddenly become artists, psychologists, students of efficiency, masters of book-keeping and card index systems, every man jack of us keen to smell out a business proposition, quick to run after it, and competent to carry it through—then, well then, I'll tell you what would happen, *the game would be up a gum tree.*

I try very hard to be intellectually honest. If there had not been a big army of rotten retouchers in my youth, I could not have shifted from city to city, from country to country, never lacking employment, and now I am grateful to my inefficient competitors, for their lack of ability keeps me living. Let us realise very fairly and squarely that we know what we are talking about when we glibly speak of the standard of professional portraiture, and shed tears over the retouching and pathetic wail that only 3 per cent. of the community spend money on photographs. I think if I were interested in getting the motor industry to advertise with me, I could make out a good case that less than 3 per cent. of the public spent money on automobiles! Add 50 per cent. to the capabilities of every photographer in Great Britain, and, *relatively we would be exactly as we are at present.* And at the same time do not let us talk too much of educating the public taste. Given a 100 per cent. increase in the artistic perceptions of our clients, despite our 50 per cent. improvement, we would be worse off than ever, for the extreme art lovers would have no photographers clever enough to satisfy their fastidious tastes, and at the lower end of the scale the poor worker (already gingered up 50 per cent., mark you) would find himself, like Othello, his occupation gone. Figures are funny things and can be made to prove anything. I could turn this 3 per cent. upside down, reduce and intensify it, split it up into decimals and vulgar fractions, square it and make rings round it, for, as we all know, there are three kinds of lies—common or garden lies, damned lies and then statistics.

When is the right side of a sitter the wrong side, and are we right in taking the right side which happens not to be the right side, or would it not be right to take the wrong side which happens to be the right side? That was Mr. Swan Watson's conundrum at the recent conference, and it certainly is well worth discussion, so also is the ex-president's opinion that the habitual expression was of more value than the fleeting.

I think we have exaggerated somewhat the idea of the left side invariably showing more beauty than the other, but admittedly it is seldom that both sides are equally good. The point of discussion is: Are we mistaken in photo-

graphing that side of a client's head which shows the features at their best, and avoiding or minimising irregularities, and would not better likenesses be secured by taking what we formerly termed the *wrong* side, concentrating on, rather than avoiding "points" which may not be beautiful, but which are individual and characteristic? And a supplementary question must be asked—is character portraiture of that nature likely to prove acceptable with the public?

Lord Nelson, so I am told, had only one eye, and I quite believe he would not have been offended with the work of an artist who made a point of that, but he would have been very angry with the painter who offered him a miniature of Lady Hamilton making a special study of a buckled ear. I know full well that, as Mr. Solomon J. Solomon says, character is a breakaway from the normal, but sad experience has proved to me that individualism, the most beautiful thing in life, is appreciated by a very small section indeed. I fancy the "wrong side" portaiture, if adopted by Mr. Swan Watson, would result in a masterpiece of his having the head cut off and deposited in the safe of an Edinburgh merchant prince. A few cranks here and there (generally poor fellows, brother artists as a rule) will take real character portraits, but the great majority want flattery, *and need it.*

Of course we all know the "just as I am," Cromwell-and-his-warts individual, and we have to humour him accordingly. When we are asked for the candid truth, it pays better to give what is really wanted, the *candied untruth.* When I had the misfortune to live in Scotland I was once honoured by a commission to photograph the MacTartan of Haggisvale. He had enough character in his face to "gar the salmon loup" (as I heard an apprentice say in what I understand is "braid Scots"), and he told me that no one had ever taken him to his satisfaction, and that he wanted *no retouching.* I always know I am up against something when I hear that a client has never yet had a good photograph. I started with a prejudice in this case, and with scarcely any hope. No selection was possible, for the only way to find the less bad side was the method of the Irish jarvey with the hotels—whichever you chose you'd wish you had picked the other. The noble chieftain arrived when the light was at its worst, and was taken without the support of head-rest. Only one negative—a 12 by 10 head was steady. Oh, face of Peterhead granite, what a dial was there, my countrymen! Panchromatics, light-filters and suchlike aids to the better rendering of colour were then unknown. Unfortunately, I had got the negative sharp, it was under-exposed and raw, and ten thousand freckles leered up at me unashamed in all their clear glass nakedness. "No retouching" on this result did not look like a winner. I consulted Briggs, the cockney retoucher. "Fat oil and plat" was his solution, which sounds cryptic, so I will explain. We printed in P.O.P. and platinotype then, and a much finer touch was required for the gelatine paper. As stronger negatives were made for "plat," fat oil of turpentine was frequently used as medium, and a coarser stipple employed. So I fat-oiled, got my No. 2 Hardtmuth sufficiently blunted, focussed the sighting distance in the accepted way by extending the fingers of both hands, tandem fashion, from nose to negative, and then proceeded to "give it plat." I slogged at it for hours, then Briggs had a go. We cross-hatched, stippled, drew figure eights, inverted commas and barbed-wire entanglements all over the face. We wound up by matt-varnishing, stumping and thumbing gamboge on the reverse side. The print was made and mounted, a splendid example of the no-retouching school, and "smallpox or leprosy?" would have been an appropriate title. I was dead scared at the prospect of the MacTartan's wrath, but, to my great relief, he hailed the result with delighted hoochs of joy, danced a pibroch and tossed a caber in the reception-room. "A wud ha'e nae scartin' at ma face," he said with great dignity, as he invited me to partake of cock-a-leekie and whuskey.

To this day I verily believe, in the clachan of Haggisvale (by the way, what is a "clachan"?) hangs that immortal work of realism, the unretouched portrait of the mighty chieftain in whose waters you would not dare to shoot grouse.

After all, what *is* the real man, and, as Browning puts it, who is to arbitrate? Most of us spend our lives in very paltry concerns, and our faces bear traces of the thousand and one little worries which ought not to have bothered us a bit. Indigestion may be mistaken for intellect, and a soft focus portait of a myopic youth (black hair sharp and carefully spot-lighted) with blackleaded face, and fist clenched to his jaw may *mean* "character," yet convey instead the impression of neuralgia. When we see craftiness, meanness, bigotry and other unsocial qualities stamped all over a face, is it good business to feature them, or would it not be better to work for a fleeting glimpse of something different? In my opinion there can be but one answer. Then, what is the habitual and what the fleeting, and once again, who is to arbitrate? Mr. Swan Watson would be proud to have ancestors whose characteristic expression was that of scaring less fortunate fellow-men off God's earth. It is entirely a point of view. "Yon birkie ca'd a lord" better expresses my attitude to the man for whose ghillies I have the profoundest contempt. Don't think the recent elections have unhinged me. I am not talking politics, but character study, and am laying stress on the fact that different men see different things in the same subject, and a "character study" is frequently a reflection of the artist rather than one of the subject. Then again, a man is not one man, but many men, at different times. What is a characteristic portrait of Lloyd George. Would not it be true to say that there are scores? And yet, which one is the favourite one of Mrs. Lloyd George? I venture the opinion it would be a smiling one.

The other day I was reading the reminiscences of a great man by his widow. One thing struck me forcibly, and that was that the writer had far more loving memories of the little silly jokes of her husband than of his many public triumphs. That, I should say, is a common feeling. We see the austere judge with dignified mien, but a different man is seen by the little son chasing his daddy at play in the garden. Let us tell the public that every man is a dozen men, that is to say, requiring a dozen different positions, and that will be all to the good. But if we are one-plate artists, look for the better side, forget about Nelson when you have a boss-eyed client, think of cheerfulness, and be ready to snap the fleeting smile, and the box-office will know there is something doing.

J. Effel.

The Salex Review, issued by the City Sale and Exchange, 81, Aldersgate Street, London, E.C.1, contains in its current issue some notes on spot lighting, co-operative advertising, soft-focus lenses, in addition to lists of numerous bargains in cameras and other apparatus for professional photographers. The "Review," which appears monthly, will be sent regularly to any bona fide professional photographer on application.

Imperial Plates, Film and Paper.—We have to thank the Imperial Dry Plate and Film Co. for sending us one of their calendars for 1923, bearing their well-known trade mark of a lion rampant and usefully calling attention to the well-known leading products of the firm. We believe the calendar is obtainable by professional photographers and photographic dealers making application to the company at Cricklewood, London, N.W.2.

A METHOD OF REGISTRATION FOR MULTIPLE PRINTING.

[To those enthusiasts who still work the multiple gum process of printing, some method of exact registration is of great importance. In the following paper, from the current issue of the "American Annual of Photography," the writer suggests the use of a glass plate to which slips of glass are cemented, to form in part two sides of a square. To supplement these, strips of gummed paper are placed on each of the four sides of the registration mask, and lines drawn which are made to coincide with others placed upon the printing paper. The suggestion as to the use of good paper for printing is an excellent one, as however careful one is to make the correct provision for future registration, it will be found impossible to prevent overlapping if the paper has swollen or stretched unequally during the process of development.]

So much has been written by capable writers in the photographic magazines about gum printing that I hesitate to offer anything on the subject. However, taking a chance that my method for perfect registration for multiple gum printing is new, I will endeavour to explain it, hoping some of the newer gum workers will gain some points by reading it.

Fig. 1 is a piece of plain glass somewhat larger than the size of the negative to be printed from. On this glass two narrow

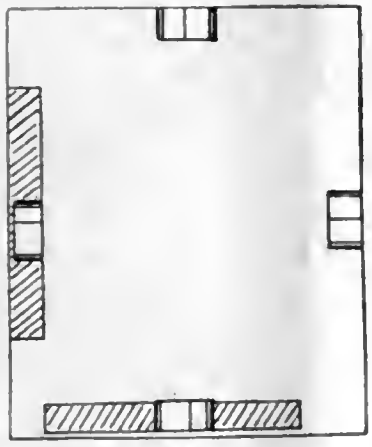


Fig. 1.

strips of glass are cemented to form the angle of a true square, leaving an opening at the corner which keeps grit and dirt from collecting. These strips can be cut from an old cleaned negative. The cement I use is called Spittler's cement, bought in a Woolworth store. Paper or wood strips could be used, but there is a chance

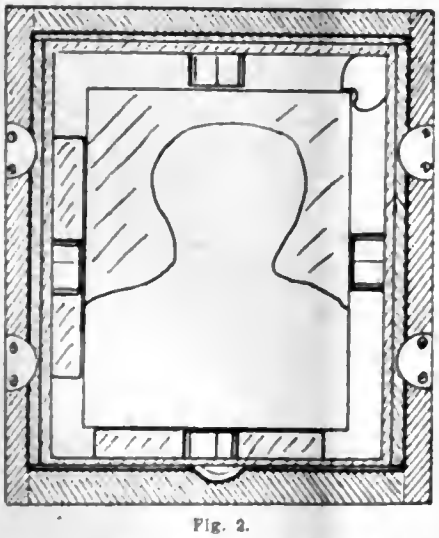

Fig. 2.

of atmospheric conditions swelling or shrinking them, and this must be avoided if perfect registration is desired.

On the sides, top, and bottom paste a piece of gummed paper where the centre of the negative will come. Now draw a line across in the exact centre from side to side, and top to bottom. These marks are shown in fig. 1. Fig. 2 shows a negative in place in the printing frame, which, of course, is larger than the negative used to print from. Care must be taken to hold the negative snug against the glass sides. For this purpose I use a small spring shown in the upper right corner in fig. 2.

The paper to be coated should be of a good quality and one that does not stretch much. Either before or after it is coated the back of it is marked off with a T-square, making a line about three-quarters of an inch at the edges in the centre of sides, top, and bottom. For this purpose I use a drawing-board which has a line drawn across the centre from top to bottom and side to side. The paper should be about an inch larger than the negative, which allows a half-inch margin to facilitate future coatings. It is tacked to the centre of the board face down, and the registration marks are made with the T-square. In this way the marks are perfectly square, even though the paper may not be. Besides the registration marks it is advisable to make some distinguishing mark, so that the image from the first printing will match the negative at future printings. Occasionally the subsequent coating

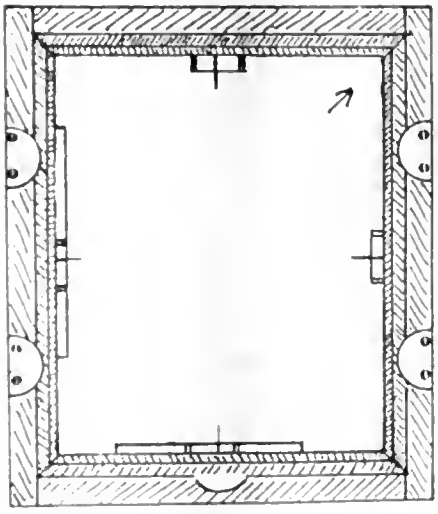

Fig. 3.

may cover the first so that the image cannot be seen. I make an arrow in the top right corner.

Fig 3 shows the printing frame with the negative in place, a piece of coated paper face down and the registration marks made to match the marks on the glass with the guide strips and gummed paper registration marks. The piece of paper shown is the exact size of the printing frame, and sections have been cut out at the registration points. The arrow shown in the drawing is thus supposed to be on the back of the paper. These must all be kept in place until the back of the printing frame is placed in position, when it is ready for printing.

After the print is developed, dried, and re-coated, all that is necessary for registering is to lay the paper so that the arrow is in the top right corner, and the registration marks again match each other. This can be done repeatedly for as many printings as one wishes to make.

If there should be any stretching of the paper, it will be from the centre, and will be distributed four different ways, and not noticeable. In the usual method of registering the negative and paper from the corner of the printing frame, the stretch will be from one point in the corner to the opposite corner, and if large sizes are used there will be quite a noticeable overlapping of the image in the other printings.

B

Be sure to select a good quality of paper, fairly heavy, and one that does not stretch. A good test is to cut a strip of the paper that it is desired to use, say about 12 inches long and 2 inches wide, so that the ends are square. Cut this in half, so that you have two strips 1 inch wide. Now soak one of these strips in water for about an hour, and then dry. Then compare the length of the two. The one that was soaked will be longer if the paper is unsuitable.

For multiple printing use a minimum amount of pigment, and coat very thin. My own method is to print very strong with a thin coating of pigment, so as to get a good impression of the high-lights. When these and the half-tones are satisfactory, I give a heavier coating—that is, more pigment—giving a shorter exposure so that there will remain nothing but shadows from this printing, the high-lights having washed away.

WILLIAM H. ZERBE.

Assistants' Notes.

Notes by and for assistants will be considered for this column. Payment for accepted contributions is made on the first of the month following publication.

Assistants and their Training.

FROM time to time letters and remarks appear in these columns with regard to the difficulty of getting really well-trained and thoroughly-competent assistants. All regret the fact, but few, if any, I think, point out any remedy. But surely a remedy would be better than the regrets.

It is strange, if one stops to think of it, what a difference there is in the preliminary training of, say, doctors, schoolmasters and the would-be assistant in an exacting business such as photography; for I am sure that all those who know it best will at once grant that photography *is* an exacting business.

The doctor-to-be and the prospective schoolmaster both serve a long pupilage to their professions, study for years along well-defined lines, but the course of the pupil in photography is much more haphazard. He (or she) usually serves an apprenticeship of two or more years, putting in more or less time in each department, and then is turned off to pick up the rest for himself as best he can. In the case of girls this method is perhaps less harmful than in the case of youths, especially those with ambition and the desire ultimately to own a business of their own; and it is no use to smile at the serious lad who says he means to have a business of his own one day, for he generally ends in doing it.

I think, perhaps, one of the most useful things the P.P.A. could do would be to frame a course of study such as could be followed out by girls and youths, for the combined wisdom and experience of the council members ought surely to frame nearly an ideal course. Meanwhile, I would like to offer a few suggestions from my own experience.

First the pupil should be impressed with the fact that there is certain useful knowledge which he or she cannot hope to obtain in business hours, but which, if they are ambitious enough to desire it, must be sought outside, in technical classes and by private study. But it is a knowledge which amply repays both lads or girls for their trouble.

First, there is the real necessity for both to reinforce their technical knowledge by a practical training in Art, freehand, black-and-white and colour work, for such practical knowledge ultimately raises the whole tone of their work, renders it more valuable, and saves the photographer from many pitfalls to which he is liable without it. The study of black-and-white work is especially useful, as it conveys a knowledge of tones and tone values which are of the greatest use both in outdoor and indoor operating, and also in working up and judging the use of colour screens.

Girls, again, may with advantage give extra time and attention to colour work, which it will later on often pay them to specialise in, for it is of great added value to a receptionist or finisher to be able to colour well and intelligently, not merely tinting, but working, if necessary, from a freehand basis.

To a lad, again, a term or two devoted to elementary chemistry is often of much service later on, enabling him to grapple more intelligently with the troubles that may arise in the course of his dark room work, or in the evolving of new methods or formulæ, in the understanding use of his working materials, the necessity of cleanliness, and proper working conditions.

This is all on the technical side, but to the pupil who is keen to launch out for himself there is other knowledge, the possession of which is of the utmost importance.

All owners of businesses need a sound working knowledge of ordinary bookkeeping, and its possession would have kept many a good worker out of the bankruptcy court. It is most essential to be able to keep a proper check upon all materials used, out-of-pocket and running expenses, and to be able to cost up the production of any quantity of work so that proper quotations may be given and work may not be done at a loss, as it has been in many cases, owing to ignorance of the actual cost of turning it out. Also, in case of disputes with income-tax officials, the production of properly kept books on the usual system, will greatly simplify matters, and avoid much heart-burning and bitterness; while, should the owner wish to sell his business, there is no better credential than the production of well-kept and easily-understood books.

It is the rule with all large concerns always to put aside a certain percentage of their takings—not profits—to a reserve fund, to meet any unexpected emergency that may arise, and a very wise rule, too; but I am afraid not one photographer in twenty carries out this rule, with the result that when some heavy charge arises for structural alterations, new apparatus or other trouble, he either has to borrow capital, or draws heavily upon his profits. This is not a wise or businesslike way, and only leads to much worry and anxiety; but if the young photographer started off along the ordinary business lines, rigidly putting aside this reserve and leaving it untouched, many would be enabled to carry on instead of coming to grief.

Also, the prompt, accurate businesslike sending out of accounts results in quicker payment from customers, and easier payment of wholesalers' accounts by the photographer, with resulting saving in discounts, and better feeling between maker and user of materials.

There are many quite ordinary business rules and methods of which many young photographers seem quite ignorant, with the result that they are landed in many needless troubles. Adequate insurance of premises and stock, proper insurance of casual help under the Employers' Liability Acts, proper conformity with any local by-laws as to days and hours of closing, and proper stamping of insurance cards, all call for the necessary knowledge; as also the local rules respecting buildings, space of open backyards, and so on, in large towns, and also such things as the laws of ancient lights, where a photographer contemplates building a studio. It is infinitely easier—and cheaper—to settle these matters amicably with your neighbours beforehand than to go to law after, and to study the laws of leases and tenants' rights beforehand than after the lease or agreement has been signed. All matters as to repairs, out and inside, should be made quite clear, and also the ownership and valuation of the studio itself, or any other workrooms the young photographer may erect. These look small at the beginning of, say, a 21 years lease, but let the photographer expend perhaps two or three hundred pounds, and as the end of the lease draws near, it becomes a very large matter.

Another very useful study, for either the lad or girl assistant, is lettering, for often the ability to write neatly and quickly titles under prints, names, dates or announcements for the window, with a clear style that has nothing "home made" in its look, is most valuable, especially in the higher class studios. It is not a lengthy study, but certainly most useful.

Another section of knowledge which is often of benefit is that related to printing and process reproduction, the ordering and making of blocks, their correct use and variety. Often photographers are called upon to supply prints intended for reproduction and block making, and a little correct knowledge of the process would enable them to supply much more suitable prints, thus entailing a considerable saving to the customer in after-work upon the print by block makers.

It is always useful for the young and enterprising operator who is launching out on his own account, or is taking up the management of a branch studio, to mix as much as possible with other business men, of no matter what kind of business, and keep his ears well opened, for in this way he will gain many a valuable hint from the old-stagers. Modern business is a complex thing, and if he proposes to run an amateur department, he will be in just the same position as any other dealer, who buys and sells to make a profit. Any mechanical knowledge, too, of whatever kind he can pick up will never come amiss, for there are a hundred

and one small jobs which crop up in any studio from time to time. Also to most photographers, a sound working knowledge of framing and mount cutting is necessary, as most photographers do more or less of this kind of work, and it all goes to swell the annual profits.

The case of the girl assistant is somewhat different, as she less often has any desire to own a business, and looks upon it more as a career to last her until her marriage than as a life work. Still, she hopes to make as good a living out of it as possible up to that time, and to that end needs a good deal more knowledge than her apprenticeship usually furnishes her with. If her work lies in the reception room, she, too, will need a thorough knowledge of modern bookkeeping, the preparing of balance-sheets, and so on, and the checking and control of amateur stock and cameras. Also, some knowledge of the framer's business, and any other side line, such as prints or pictures which the photographer may run, *e.g.*, lockets and pendants, and so forth. Also, in most studios of the better class, a typewriter is now used for correspondence, and also card systems and other modern office appliances for time-saving. She, too, will need an art training, and some knowledge of the modern art of salesmanship will be of use to her. The cultivation, too, of keen powers of observation, and memory, is a very great asset, while in some studios the ability to speak and write correctly in French and German is most valuable; at any rate, she needs to study the whole art of a saleswoman and correspondent.

There is, too, another class of woman assistant, less seen but no less important, and that is all those who are in any way connected with the finishing of negatives and prints. To them the knowledge of drawing and black-and-white work is of the first importance, outside the mere correct technique of their work, such as the use of air brush, dry-mounter, etc. Much of this knowledge, of course, they will have to seek outside the studio, where all is bustle and work, with no time to teach juniors who do not know, but I can assure them it is well worth the expenditure of spare time and money to attend art classes.

Of late years many women have become first-class operators, and they, too, need a sound art school training, and a good knowledge of the technical side of dark-room and printing methods, to which end membership of a good photographic society and regular study of the various photographic journals are very helpful.

It all comes to this: You cannot expect something for nothing in the labour market, and if you don't put in years of expensive college training you must at least be prepared to put in a reasonable amount of your spare time to the necessary study, along sensible lines, in order ultimately to reap a good reward. I would strongly urge upon all parents and those responsible for launching out young hopefuls in photography that the latter get the necessary training outside the studio, for it is infinitely easier in every way to acquire this knowledge while young, than later on, when harassed with greater responsibilities and cares. The result, I am sure, would be a help both to master photographers and assistants.—G. E. H. G.

FORTHCOMING EXHIBITIONS.

December 9 to 31.—Rochdale Amateur Photographic Society. Particulars from the Hon. Secretary, W. Lord, 10, Derwent Street, Rochdale.

1923.

February 5 to March 3.—Northern Photographic Exhibition, City Art Gallery, Manchester. Latest date for entries, January 12. Particulars from the Hon. Exhibition Secretary, Walter Johnson, 30, Hartington Road, Chorlton-cum-Hardy, Manchester.

February 10 to 24.—Scottish Photographic Salon. Particulars from the Secretary, George A. Ross, Northfield Cottage, Brechin.

February 12 to 14.—City of London and Cripplegate Photographic Society. Latest date for entries, January 29. Particulars from the Hon. Secretary, J. J. Butler, 7, Gresham Street, London, E.C.2.

March 1 to 8.—Birmingham Photographic Society. Latest date for entries, February 15. Particulars from the Hon. Secretary, J. E. Breeze, 178, Broad Street, Birmingham.

March 2 to 31.—Pittsburgh Salon of Photography. Latest date, February 5. Secretary, Charles K. Archer, 1,412 Carnegie Building, Pittsburgh, Pa., U.S.A.

March 13 to 16.—Exeter and West of England Photographic Exhibition. Particulars from the Hon. Secretary, R. W. J. Norton, 4, Buddle Park, St. Thomas, Exeter.

March 15 to 24.—Photographic Fair, Holland Park Hall. Secretary, Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, December 4 to 9:—

Colour Photography.—No. 33,228. Production of screens for colour photography. R. C. M. de Bercegol.

Colour Photography.—No. 33,656. Natural colour photography. J. Dimsdale and J. Kean.

Cameras.—No. 33,653. Photographic cameras. T. K. Frank.

View Finders.—No. 33,403. View finders for cameras. H. V. Flinn.

Tripod Heads.—No. 33,339. Heads for camera tripods, etc. J. Méry.

Developing Tank.—No. 33,203. Tank for developing, etc., photographic films. M. Rycott.

Process.—No. 33,331. Capillary process of exchange of liquids in photography, etc. L. Lumière.

Telephonic Transmission of Images.—No. 33,655. Telephonic transmission of images. J. Dimsdale and J. Kean.

Projection Apparatus.—No. 33,436. Optical projection apparatus. V. Bridgman.

Photometer.—No. 33,293. Photometer. E. J. Taylor.

Cinematography.—No. 33,595. Apparatus for production of cinematographic films. T. A. Milla and Zoechrome, Ltd.

Cinematography.—No. 33,016. Exposure cinematographs. Firm of C. Zeiss

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

Exposure Meters for Copying, Enlarging and Reducing.—No. 187,077 (August 16, 1921). An indicator which is automatically operated on extending the camera is provided to indicate data

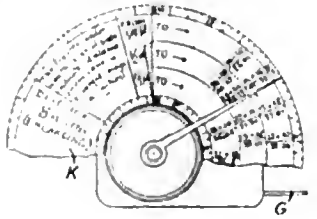

Fig. 1.

Fig. 2.

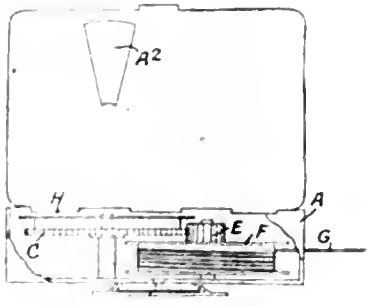

Fig. 3.

which alter with the extension of the lens beyond the infinity point or stop, as, for example, the reduced *f*-value of the lens aperture, the change of exposure required, the degree of enlarge-

ment or other data. The indicator may consist of a pointer rotating with relation to a fixed disc as in fig. 1, or of a disc rotating behind a slot in fig. 4, or of a blind or a simple roller moving behind a slot as in fig. 7. The mechanism for rotating the disc or pointer comprises a cord G, secured to the bellows by an adjustable drum S (fig. 2), adapted when the bellows is extended to rotate a drum F (fig. 3), round which it is wound against the action of a spring enclosed in the drum. This motion is transmitted through cogs E, C, to a dial H, of which the markings are visible through a slot A^2 in the lid of the indicator container A. In this form a second indicator disc K may be mounted on the outside of the indicator case A on a boss J (fig. 5), the boss carrying also an adjustable pointer L^2 with reference to which the inner indicator disc H (fig. 3), rotates. The zero or normal mark on this inner disc acts as a moving pointer for the outer indicator disc. A magnifying lens L^1 may be secured in the boss J to facilitate the reading of the inner indicator. The external indicator may be used alone, in which case the inner

Fig. 4.

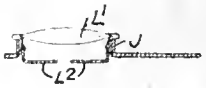

Fig. 5.

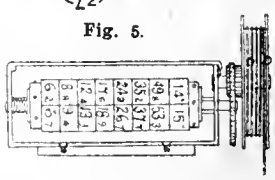

Fig. 6.

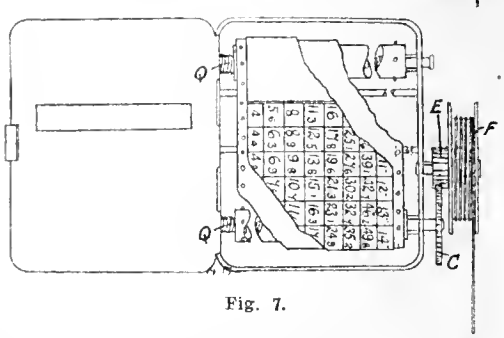

Fig. 7.

indicator is replaced by a pointer. The roller blind indicator, shown in fig. 7, is operated similarly by a drum F and cogs E, C, and is arranged to have its zero adjustable by moving the cog C out of engagement with the cog E against the action of spring Q. The roller indicator is arranged as shown in fig. 6. Various arrangements of the lens data on the indicators are shown on the drawings, and the camera may be provided with a number of interchangeable indicators corresponding to lenses of different focal lengths, the data shown being the *f*-ratios, the various degrees of enlargement or reduction, the positions of conjugate foci, and the duration of exposure compared with that for a like aperture at infinity point or with that necessary for copying full size.—W. G. Rickman, 11, St. Mary Axe, London.

Photographs by Electricity.—No. 188,030. (July 23, 1921.)—A glass plate having a thin transparent metal coat upon which is a thin layer of selenium crystals, is in electrical connection with a battery. A metal plate is connected through a switch to the battery, and between the selenium and the metal plate is arranged a film which is sensitive to electricity. It may be of paper slightly moistened with a potassium iodide or with a cyanide solution. When a photograph is to be taken, the film is pressed against the selenium by means of the plate, and light passing an objective is caused to fall upon the glass. The switch is then closed either instantaneously or for a definite interval of time, with the result that the different portions of the film will be variously affected by the current by reason of the varying resistance of the different portions of the selenium as affected by the incidence of the rays of light. The film can then be developed by any usual process.—Otto von Bronk, 2, Defreggerstrasse, Treptow, Berlin, Germany.

The following complete specifications are open to public inspection before acceptance :—

Colour Photography.—No. 189,813. Process for the rapid production of screens with polychromatic divisions for colour photography. R. C. M. de Bercegol.

Cinematography.—No. 189,774. Method for treating cinematographic films and apparatus therefor. Pathé Cinema, Anciens Etablissements Pathé Frères.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

Novogas.—No. 429,942. Sensitised photographic papers and postcards. L. Gevaert & Compagnie, 23, Sapte Straat, Vieux-Dieux, Belgium, manufacturers of photographic materials. September 24, 1922.

New Books.

The Chemist and Druggist Diary, 1923.—In addition to its diary pages this large volume, issued by our old-established contemporary, contains numerous features which make it invaluable as a daily source of information for pharmaceutical chemists and others. A most valuable feature is the "Buyers' Guide," a classified index to the innumerable chemicals, proprietary preparations and other goods which are sold by chemists. Each entry indicates the various sources of supply in this country. Other literary pages contain a digest of current legislation applying to the sale of spirits, patents and trade marks, income and corporation profits tax, import, stamp and excise duties; and there is even a largely successful attempt to render intelligible the provisions of the National Insurance Acts. The "Diary" is issued to annual subscribers to the "Chemist and Druggist" from the office of that paper, 42, Cannon Street, London, E.C.4.

Sensitometry of Photographic Emulsions.—A "Scientific Paper" (No. 439) has been issued by the United States Bureau of Standards by way of description of the tests and measurements of the characteristics of sensitive photographic materials which have been made during the past few years by Raymond Davis and F. M. Walters, Junr., of the Bureau staff. The publication, which runs to 120 pages, contains a detailed account of the apparatus and methods of testing which have been adopted by the Bureau as standard practice. Whilst both of these are broadly along the lines of Hurter and Driffield, modifications have been made not only in the forms of the exposing and density measuring machines, but also in the manner of expressing the results. The greater part of the booklet is taken up by charts and curves showing the spectral sensitiveness, fog density, characteristic curve, etc., of 86 different emulsions, representing, so it is stated, practically all the brands of emulsion (made in the United States) coated on glass and celluloid. The trade names of the products are, however, withheld. The "Paper" is certainly a contribution to the literature of sensitometry of photographic materials which those interested in the subject will wish to have. It is issued by the Superintendent of Documents, Government Printing Office, Washington, D.C., price 35 cents.

Subject Index to Periodicals.—The compilation of an index providing a key to the chief periodical literature of scientific and technological subjects, which was begun during the war by the "Athenæum," has been continued by the Library Association, 33, Bloomsbury Square, London, W.C.1. A subject index covering periodicals issued in the years 1917-1919 has now been issued as a volume of 555 pages of 12 x 10 inches. It contains 15,000 entries collected from 400 periodicals, representing the chief physical (including biological) sciences and the various branches of technology. Optics and photography have come within this survey, but whilst the former has yielded barely a column of entries, the latter provides particulars which occupy nine columns. The compilation marks an enormous amount of close work done with meticulous care and provides librarians of public or private institutions with a ready means of discovering some item of information which consultants of their collections of periodicals may be seeking. Its usefulness for this purpose would, we think, have been increased had a list of the periodicals which have been examined been included with the index itself. Without such an indication it is not possible to say beforehand whether it is worth while to consult the index at all in the aim of tracing some item which has been known to appear in a given publication. The Index is published by the Library Association itself, price £1 15s. net.

New Materials.

GRIFFIN'S "HAPPINESS" CHRISTMAS CARD MOUNTS.—This series of attractive folder cards, made in two sizes, for ¼-plate or V.P. prints, are supplied by Messrs. Griffin, Kemble Street, Kingsway, London, W.C., in three designs, each printed, in one or more colours, upon fine ivory card. A slip-in section with grey and white border is provided, suitable for both horizontal and upright prints. The mounts are supplied in packets, containing two cards of each design, making six cards in each packet, and the prices are 1s. 6d. per packet for ¼-plate and 1s. 3d. for the V.P. size.

Messrs. Griffin are also supplying an excellent selection of photographic calendars, with cut-out openings for prints. These are made

in various sizes suitable for prints from V.P. to postcard, and in either the upright or horizontal pattern. The mounts are cut from good quality stout card of either grey or brown colour, with a cut-out opening in an overlay of white or cream. Tasteful borders are printed or embossed around these openings, and a calendar is attached to the lower portion of the mount. The prices for these mounts are, for the V.P. and 3 in. by 2 in. sizes, 4s. 6d. per doz.; for ¼-plate and 4¼ in. by 2¾ in., sizes, 5s. 3d. per doz.; and for postcard size, 6s. per doz.

New Apparatus.

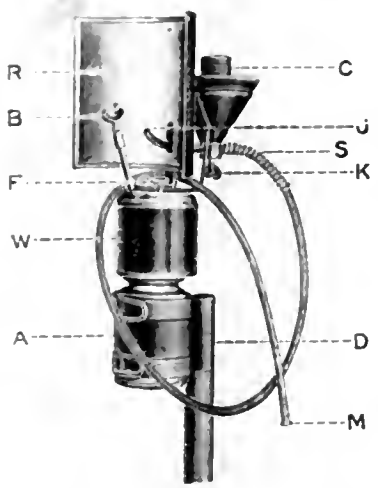
Acetylene-Magnesium Flash Lamp. Sold by Jonathan Fallowfield, Ltd., 146, Charing Cross Road, London, W.C.2.

To the ferrotype worker who anticipates the falling-off of his work during the winter months, owing to unsuitable light, the flashlamp recently placed upon the market by Messrs. Jonathan Fallowfield will come as a boon. At fairs and markets held at this time of the year the camera has to be put aside at an early hour, and when most of the business could be done the light is too bad to allow of even a prolonged exposure. But with this lamp, which includes an acetylene generator combined with a flash-lamp for magnesium powder, the camera will find a new lease and business will be possible at all times and under any conditions. At the cost of only one penny per flash sufficient light may be given for the usual small group, while for single figures the light would be more than ample.

The lamp itself is of excellent design and of strong, substantial make, capable of withstanding heavy, continuous use. It is made in four parts, viz., the carbide container A, the water reservoir W, the magnesium chamber C, and the reflector R. About 4 ounces of lump carbide of calcium are first placed in the lower chamber. The reservoir, which screws to the top of this, is then filled with water and is screwed into position. The magnesium chamber, which is the funnel-shaped vessel at the rear of the reflector, is then filled with pure magnesium powder and the lid securely screwed on. This vessel is then fixed to the top of the reservoir by means of a milled nut working on a bolt, which also provides the means for fixing the reflector in position. The powder jet, J, projects through an aperture in the reflector and its actual position may be regulated by the nut and fork of the powder box. Attached to the lower chamber is a piece of strong brass tube, D, which allows the lamp to be fixed to a broom-handle or other stout stick, which should have a pointed end, and thus, when driven into the ground, make a stand for the lamp.

To start the lamp it is now only necessary to turn the milled head F, on the right-hand side of the reservoir slightly to the right; roughly, two turns are necessary. When water drips from a small tube into the carbide chamber gas is immediately generated and flows along the upright tube to the burner B. After twenty to thirty seconds a light may be applied to the burner and a powerful flame results. This light is now kept burning and serves a double use: not only is it a means of burning the magnesium, but it is also an attraction to customers. At the bottom of the funnel-shaped vessel will be found a key K. This communicates with a valve over a small measuring chamber, and by turning the key into a horizontal position with the light the valve is opened and the measuring chamber becomes filled with magnesium. The key is then turned towards the light and the valve closes, thus preventing powder from falling and ensuring an equal amount being used for each flash. At the rear of the apparatus is a rubber tube M, which is attached to the small chamber. To make the flash the operator has only to blow into this tube when the magnesium is conveyed by means of the jet, shown in the front of the reflector, to the flame. It has been found necessary to have as large a flame as possible to ensure complete burning of the magnesium; but this is an easy matter, only requiring correct adjustment of the water valve. It should be borne in mind that pure magnesium powder only must be used, and not the explosive flash powders.

The only part of the apparatus requiring careful adjustment is the powder jet, which should deliver the magnesium into the hottest part of the flame, for complete combustion. But this adjustment is easily made, and when once found to be correct the milled head is screwed down and the lamp requires no further alteration. A rubber ball fitted with a brass tap may be obtained to blow the powder into the flame if the worker prefers this to the ordinary method of blowing; but this is only a refinement. The price of the lamp



complete as described above is 30s. net, while the ball and tube are supplied for 4s. 6d. extra.

At such a low figure we feel sure that the ferrotype worker will quickly avail himself of the opportunity to possess this equipment, as the first cost would soon be covered by the additional work possible.

A BARNET CALENDAR.—Messrs. Elliott & Sons are distributing to professional photographers calendars for the coming year designed and printed in the bold tasteful style which has been followed for some years. Any professional photographer, who may not have received one, can obtain a specimen on application to Messrs. Elliott, Barnet, Herts.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

WEDNESDAY, DECEMBER 27.

Croydon Camera Club. Conversational Evening.
Rochdale Photographic Society. "Beginners' Troubles."

THURSDAY, DECEMBER 28.

Coatbridge Phot. Assoc. President's Night. R. L. Collins.
Edge Hill Camera Club. "Amateur Photographer," 1921, Prize Slides.
Hammersmith Hampshire House Phot. Soc. "The Plate and the Photographer." C. M. Thomas.
Letchworth Camera Club. "Holiday Slides." Members.
North Middlesex Phot. Soc. "The Autochrome Process." J. F. Nisbett.
Richmond Camera Club. "Flashlight." A. Dordan-Pyke.

FRIDAY, DECEMBER 29.

Rochdale Phot. Soc. "Portraiture." A. Benson Ray.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, December 19, the president, Mr. W. L. F. Wastell, in the chair.

Mr. H. T. Meredith delivered a lecture, entitled "Gravure." The lecturer said he proposed to deal with the question of gravure printing from a practical point of view, and from the standpoint of the large firm catering for this class of work. Processes of printing could be placed under three groups, each characterised by the formation of the printing surface. Typographic printing required a relief image as in the case of illustrations when the image was etched in relief. Planographic processes were surface printing processes, and in this category would be placed ordinary litho. or offset and collotype. The image in these cases presented a flat or unbroken surface. The third group included intaglio printing, in which the image was engraved or etched below the plane surface. The name intaglio really meant carving out, and as an illustration an engraved monogram upon silver could be made to produce a print in the same way as the gravure printing block. The early types of aquatint or mezzo engraving, used a flat plate, which, after inking up and wiping off, could be printed by a hand-press only. These processes were possible before the advent of photography, but photo-aquatint and photogravure were early examples of the use of photography for printing with inks.

Rotary photogravure, as it was now being worked, allowed printing to take place by the aid of cylinders at a high rate of speed, with a consequent reduction of cost. The methods in use to-day were somewhat similar to those used by Fox-Talbot, with the exception that a cross-line screen is now used, while Fox-Talbot had to utilise a piece of coarse muslin. Gelatine, which was used to-day, was probably the medium used in the early process to transfer the image to the metal. The image, in either aquatint or gravure, had to be split up into a fine grain effect, and in these processes resin dissolved in spirit was utilised. After the evaporation of the spirit from the solution coated upon the metal, a fine deposit of resin was left: the metal was etched through this by the aid of aqua fortis, which presumably gave the name of aquatint to the process. A dust cloud of finely powdered resin was also used, the coating being subsequently fixed by heat. In rotary photogravure the cross-line screen was an adaptation of Ives' half-tone screen. The printing in this process was the present-day method of utilising the system employed 70 years ago by calico and wall-paper printers. Photogravure was not patented, but for many years was worked secretly.

The first step in the production of the rotary printing surface was the copying of the original by means of photography. From the negative thus produced a positive was made either upon glass or by the carbon process. No screen was used in either of these sections of the work, but all necessary retouching had to be done either upon the negative or the positive. As a large number of illustrations were required to be impressed from the same cylinder, it was necessary to draw up a dummy sheet of the lay-out. This was done by placing the carbon or glass positives upon a table with a transparent top, and with a series of powerful lamps below. While this lay-out was being placed in position a large sheet of sensitised carbon tissue was exposed beneath a negative of a cross-line screen. The tissue was then given an exposure through the transparencies, and, consequently, two images resulted upon the exposed surface: the illustrations producing a negative image and the screen a positive image. The negative image was thus broken up by the image of the screen into squares, uniform in size, but unequal in density, and each varying in proportion to the amount of light passing the positive. The carbon print was soaked in cold water and then placed upon the cylinder. This was then transferred to warm water, when the paper backing was removed, leaving the gelatine adhering to the metal. Development then took place in warm water, and the gelatine constituting the image became, when dry, the acid resist. Etching was effected in a solution of ferric-chloride, varying in strength according to the depth and tone of the image. A weaker solution of the etching chemical penetrated the film easily, and, therefore, etched deeper and more rapidly than a strong solution. It was thus possible, by varying the strength of this substance, to preserve within limits the actual tone values of the original. After the cylinder had been examined and any defect rectified by the engraver, it was fixed in the printing machine. The apparatus used at the present time supplied the paper from the web or roll, and this, after passing over the stretching rollers, came into contact with the cylinder, and so received the impression. An interesting part of this branch of the work was the actual inking of the cylinder. Thin ink was applied to the printing surface, which thus became thickly coated all over. A thin steel blade, called a "doctor," was then utilised to scrape away the ink from the surface of the cylinder, leaving a deposit only in the etched portion. As the paper passed over this cylinder it was pressed by a second roller, and in this manner was forced to pick up the ink from the sunken image. The paper then passed over heated plates, and so out of the machine. Much experimental work was now being done, said the lecturer, in the endeavour to produce successful colour prints by rotary gravure and some periodicals in America, were to-day being printed in three and four colours in one operation by this process. Upon the proposition of Mr. Marshall a hearty vote of thanks was accorded the lecturer for his clear and descriptive explanation of the process.

CROYDON CAMERA CLUB.

Mr. C. Pollard Crowther, as might be expected, drew a crowded house to hear him on "The Man Behind the Camera."

This worthy person has been heard of before. According to the usual plot, though details may vary, armed only with a spectacle lens set in a cigar-box camera, he triumphs over less gifted competitors furnished with apparatus of the most elaborate kind, which, for the purposes of the play, have been malignantly designed for the express purpose of emphasising their defeat and discomfiture. The moral is obvious, and much the worse for wear.

Thankfully it is recorded that Mr. Crowther's theme was different, and in his usual compelling manner he gave a corruscating sketch of the way in which big men do big things behind their cameras in the studio. Possibly an ultra-enthusiasm for the art of the camera, or possibly long residence among the Japanese, with their Oriental tendency to over-correction in laudatory expression, may be the exciting cause for words of appreciation generally couched in highly extravagant vein. "Bow down to the great masters of the camera, and with adoration regard them and their works," without exaggeration of language, in effect, commands Mr. Crowther.

Mundane mortals afflicted with a sense of the proportion of things may be inclined to reply "Bow-wow!" with no disrespect intended for the heads of the profession, who have done so much to raise its status.

With these preliminary remarks it may be mentioned that the President (Mr. John Keane), in welcoming the visitor, said that all would remember his last appearance, which was in the nature of a typhoon accompanied by incessant thunder-claps. A storm full of excitement and interest, but without any of the discomfort usually attending these convulsions of Nature. It is understood that the R.P.S. has recently weathered the same tempest, and doubtless a full account will appear in its journal, provided the reporter survives his task.

As Jupiter was associated not only with thunder and lightning, but with the growth of the fruits of the field, so the modern Jove is associated with the growth of camera pictures, and he induces a real fertilisation, if a little too rich for hardy plants accustomed to a simple soil. However, it is given to few to make an evening go as Mr. Crowther can, or to arouse hope for better things in the minds of beginners, or instil fresh interest among the photographically jaded.

Among the concrete ideas which emerged at intervals from the thunder-bolts of oratory, a few only were grasped by the club reporter, who experienced a very hot time. Very truly the lecturer said that progress is impossible if the worker cannot appreciate the difference between what is good and what is bad. Precisely, but how this judgment (once obtained, worth nine-tenths

of facile criticism) is to be acquired he did not explain. Probably it can only be arrived at by constant association with what is true and good, and here photographic pictorialism hardly appears to be the best environment.

"The man is eternally dammed who can see no possible improvement in his photography," continued the lecturer, another typical definite pronouncement, even if a somewhat uncomfortable reflection for some. Not quite so precise, if more poetic, was a long exhortation that all should learn to woo light, usually at an angle of 45 deg., to obtain the most sympathetic response.

In the studio the quickest exposure which is *long enough* is the best. He always advised the use of the biggest stop in portraiture, even with lenses of the longest foci. Finally, he said, he was out on a crusade to educate the public in the direction of asking for better things than stereotyped studio productions. From what he knew of professionals, he felt certain that it had only to ask and it would receive. (Applause.)

In the discussion, Mr. Handel Lucas congratulated the lecturer on so ably combining spouting with performance. Artists generally started by mastering detail before adopting the broad style, and he saw no reason why photographers should not do the same. This point might have been made plainer, for the lens maker puts into the hands of all the power to render detail, a work of laborious years with the artist. To combine this detail with breadth of rendering is, of course, another story, and the one doubtless intended by Mr. Lucas, and so taken by Mr. Crowther, who agreed. Being on his legs again, he started another lecture on other topics, a procedure repeated after every question.

Mr. E. A. Salt said the use of large stops with lenses of long foci had its limitations. In portraiture the blur of distant planes often became painfully assertive. Particularly was this the case with the ears. In reference to some remarks about the Marion Iso-Record plate, he could add his testimony to its marvellous speed with artificial illumination.

Mr. H. P. C. Harpur, possibly perturbed by Mr. Crowther's quite impersonal reference to the "eternally dammed," found satisfaction in including the Bromoilist in the same category. He fiercely pointed out that the beloved 45 deg. angle business did not often come off in landscape work. For him, front-lighting every blessed, blooming time. Mr. Crowther dissented: the long shadows in morning and evening should never be overlooked. A most hearty vote of thanks was accorded him with much acclamation.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A meeting of the Council was held at 35, Russell Square, W.C., on Friday, December 8, 1922.

Present: Messrs. Marcus Adams, Angus Basil, A. Bennett, Frank Brown, Gordon Chase, Alexander Corbett, C. F. Dickinson, R. Haines, G. Hana, Herbert Lambert, H. A. St. George, Lang Sims, R. N. Speaight, H. C. Spink, F. G. Wakefield, W. H. O. Wedlake, with the Secretary (Mr. Alfred Ellis) and the Editor (Mr. Jenkyn Griffiths). Mr. Alexander Corbett in the chair.

Arising out of the minutes, the chairman reported that he had not yet been able to call together the committee on co-operative advertising, but a meeting would be held, if possible, before Christmas.

The secretary stated, with regard to a matter in which a member was refused what he considered his rightful fees for commissioned work by a daily illustrated paper, that particulars had been obtained from the solicitor with regard to procedure in the County Court, and had been transmitted to the member concerned; but it had not been necessary to carry it further because the paper in question had since paid the money. On the matter of posting photographs to Italy, a cheque had now been received by the member concerned in settlement; the law on the subject appeared to be that if a customer ordered goods to be sent in a certain way the customer had to accept responsibility for their safe delivery. Mr. Wakefield suggested that all photographs sent abroad should be registered, not that registration assisted very much in making a claim in the event of loss, but it did furnish evidence of receipt.

A dispute, mentioned at the previous meeting, had arisen over a portrait of a Parliamentary candidate sent by a lady to a Press agent, who copied it, and supplied copies to the papers, not knowing that it was the copyright of another photographer. The secretary had written to the Proprietors' Association of Press Photographic Agencies, suggesting that its Council should consider how best to prevent any such friction arising, and had received a reply stating that the matter would be laid before the Council at the next meeting. It was resolved to write to the complaining member pointing out that the infringement was done in good faith, that the offending person was also a member of the Association, and suggesting that he should accept an offer to refund the single fee which had been received for the portrait in question. It appeared, however, that the sitter accepted full responsibility. Mr. Lambert suggested that publicity might be given to the principles governing copyright, and that members supplying copies of photographs should be advised to put a note at the back of the print stating that they claimed the copyright. Mr. Hana said that formerly it was the practice to place on a photograph the words "Copyrighted by ...," but now it appeared that the more correct form was "Copyright of ..." because the photograph was no longer copyrighted by any process of registration. The feeling of the Council appeared to be that "Copyright of ..." was the correct expression.

Letters were also read on the subject of sending films by post, and on the question of cheaper electric current, which had been the subject of previous correspondence mentioned in the minutes.

A letter was read from the secretary of the Society of Master Photographers of Lancashire, which had been asked to nominate one of its members who was also a member of the Association, to a vacancy on the Council. It was stated that the Society had put forward the name of Mr. Fred. Read.

Mr. Chase moved that Mr. Read be accepted on the nomination of the Lancashire Society of Master Photographers to fill the vacancy on the Council until the next annual general meeting, Mr. Haines seconded, and this was agreed to.

Progress was reported on the matter of the Congress and the Photographic Fair, but no new development had taken place since the matter was fully canvassed at the meeting a fortnight previously.

The secretary reported that 347 members owed subscriptions (£173 10s.), of whom 225 owed one year's subscription, and 122 two years' subscription; 194 had not signed the incorporation forms among those whose subscriptions were outstanding, and four who had paid their subscriptions had not signed the forms. He thought it well to wait until the end of the year before taking any further action. He suggested that the advisability of an entrance fee might well be considered.

The secretary then read correspondence relating to various matters on which help and advice had been afforded to members, and in connection with one letter, relating to terms for an apprentice, Mr Brown moved, and it was agreed to, that the question of payment of apprentices should be placed on the agenda of the next meeting.

The chairman, in closing the meeting of the Council, said that he thought the Council was to be congratulated on the attendance at a time of year when photographers were extremely busy. The attendance was very gratifying to himself as President, and very beneficial to the Association. He wished them all from the chair the compliments of the season. He desired also to congratulate Mr. Griffiths on the present issue of the "Record." There were many worries and harrassments attending the production of such a journal, and Mr. Griffiths deserved a meed of praise. Mr. Adams associated himself with these sentiments, which were endorsed by the Council. This concluded the business.

Commercial & Legal Intelligence.

NEW COMPANIES.

Anthony Houghton (Fine Art Co.), Ltd.—This private company was registered on December 11, with a capital of £500 in £1 shares. Objects: To carry on the business of fine art dealers, dealers in pictures, engravings and water and oil colours, picture-frame makers, photographers and printers, teachers of painting, etc. The first directors are: A. Houghton, 35, Church Road, Caversham (manager and managing director); Ellen Houghton, 35, Church Road, Caversham; Lily E. Houghton, 35, Church Road, Caversham. Registered office: 128, Friar Street, Reading.

Kodak Albums. A generously illustrated 16-page list has just been issued by the Kodak Co. of the albums for both professional and amateur use which are supplied by the company. Among the patterns are many attractive styles for prints of small size, one for prints from Kodak Panoram negatives, and also a series of loose-leaf albums. The list is issued for the information of dealers for whom an attractive counter show case, accommodating a selection of the albums, has been prepared.

News and Notes.

NEGOL INDUSTRIAL COLLODIONS, LIMITED.—This firm have taken new offices at Windsor House, Victoria Street, Westminster, S.W.1, to which address all communications should now be sent.

CAMERA CLUB.—The demonstration of flashlight portraiture with an improved form of installation which was to have been given at the Camera Club by Mr. Walter Thomas on January 1 next has been postponed until Monday, January 8.

FILMS SPOILT BY ORE.—A Chicago contemporary states that a photographer of that city had the unpleasant experience of having some exposed films ruined because he placed some samples of high-grade carnotite ore in the safe where the films were stored. The radioactive properties of the ore caused peculiar designs to appear on the films when they were developed.

CITY OF LONDON AND CRIPPLEGATE PHOTOGRAPHIC SOCIETY.—This old-established society in the city of London will hold its eighteenth annual exhibition from February 12 to 14 next. There is an open class in which first and second prizes will take the form of bronze plaques. The last day for the receipt of entries is January 29. Prospectus from Mr. J. J. Butler, 7, Gresham Street, London, E.C.2.

THE N.S. CINE CAMERA ON MOUNT EVEREST.—Messrs. James A. Sinclair & Co., 54, Haymarket, London, S.W.1, have issued two leaflets descriptive of the Newman-Sinclair cinematograph camera with which the many remarkable cinematograph pictures of the Everest expedition were taken by Capt. J. Noel. The films are now being used for the illustration of the fascinating lecture which is being delivered twice daily at the Philharmonic Hall, Great Portland Street, London, W., under the auspices of the Mount Everest Committee.

ROBBINS, MANISTRE BARGAINS.—Messrs. Robbins, Manistre, London Camera Exchange, 2, Poultry, Cheapside, London, E.C.2, send us a newly issued 64 page list of second-hand apparatus. The list fully itemises some thousand separate cameras, lenses, enlargers, and other apparatus, and is even supplemented by a loose 4-page inset which specifies such miscellaneous apparatus as cinematograph-taking cameras, projectors, etc. Throughout the list substantial reductions of prices have been carried out with the object of bringing the quotations into line with current values. Moreover, Messrs. Robbins, Manistre offer a further 10 per cent. discount for cash to bona fide professional photographers.

CATALOGUE COMPILERS PLEASE NOTE.—The "Times Literary Supplement" calls attention to the accompanying very important new regulations with respect to printed matter for the United States and Canada: "The United States Government have issued instructions that all books going to America must indicate the country of origin. British books should have the wording, 'Made and printed in Great Britain' on the reverse of the title page. Otherwise they will be detained by the Customs authorities until the law is complied with. Similarly, the Canadian Government has sent out the notification that the new Canadian Customs Regulation makes it necessary that all printed or lithographed matter of all kinds, books, pictures, etc., must be marked with the country of origin." This regulation came into effect on November 1.

INTERNATIONAL EXHIBITION, TURIN.—The exhibition which is to be held in the spring at the Newspaper Palace, Valentino Park, Turin, will embrace all branches of photography, cinematography, and optics. The photographic section will be divided into seven classes, which include every type of photographic work, together with an exhibition of materials and literature. Pictorial and colour photography may be entered in Class 1, where also a special section for portraits will be included. Class 2 is for press photographs, and Classes 3 and 4 for industrial and scientific photography respectively. For those exhibitors who visit the exhibition, special Custom House and railway facilities will be provided, while the committee, under the direction of Sir Giuseppe Ratti, will undertake to obtain hotel accommodation at reasonable rates. Full particulars of the exhibition may be obtained upon application to the General Exhibition Committee, 26, Via Oepdale, Turin.

HAND CAMERA FOR SNAPSHOTS OR CINEMA FILMS.—"Popular Mechanics" states that there is now being manufactured in America a camera which can be carried in the pocket, operates automatically with the precision of a high-grade watch, and takes either cinema pictures, snapshots, or time exposures simply by pressing a button. No tripod or hand crank is required, the camera being held in the hands and the image located by either of the two methods provided. A metal spring propels the film, at the same time opening and closing the shutter. Loading is accomplished in daylight by means of special metal magazines, six of which are supplied with each camera. The camera weighs less than 4 lbs., measures 4 by 5 by 6½ inches, and is fitted with a high-grade lens capable of producing results equalling the professional motion-picture outfit. Standard-width films are used, and each picture is ¾ by 1 inch. There are four perforations on each side of each picture, making it possible to project the pictures on any standard motion-picture machine. The camera accommodates 15½ feet of film, allowing 248 exposures, or 16 to the foot. The film is moved from one magazine to the other at the rate of 1 foot per second.

CLEANING OIL PAINTINGS.—At a lecture delivered before the Royal Academy on the preservation and cleaning of pictures, Prof. A. P. Laurie said that the question of the preservation and cleaning of pictures was not a purely scientific one, but involved certain æsthetic considerations, and there had been some confusion of thought on the whole subject. To deal first with preservation, it might be necessary, to take an extreme case, where the paint was separating itself from the canvas, to re-line the back or to remove the old canvas and back it with fresh canvas in order to save the picture itself, and this would necessitate the removal of the old varnish and replacing it by new varnish. A picture, on the other hand, might be so obscured by old, dirty, and discoloured varnish as to make it absolutely necessary that it should be cleaned in order to be able to see anything at all. In both these cases some form of treatment was necessary and justifiable.

A picture might have certain flakes of paint off it, and yet be otherwise in good condition, and in such a case it would probably be considered necessary to restore the absent pigment. Here, however, they had to consider on purely æsthetic grounds whether such a restoration was justifiable. In order that the general appearance of the picture should convey to the observer what the artist intended, it was necessary to replace the defective part, but from the point of view of the minute and careful student of the picture it was essential that such replacement should be known. This difficulty could be overcome by the taking of photographs of the picture before repair, so as to put on record what was the work of the master and what the work of the restorer.

With reference to the cleaning of pictures, it might be taken as a general principle that beyond such cleaning, which could be done by wiping with a nearly dry sponge or by rubbing up with turps, no cleaning should be done, unless it was absolutely essential owing to the serious obscuring of the original picture. Cleaning should be done under the most careful observation of experts, who were prepared to stop the process at any moment, and partial cleaning should be preferred to complete cleaning, with the danger of the removal of paint.

While he was not prepared to give a final opinion as to the safest methods of cleaning, he suggested that where alcohol is used castor oil should be laid on the surface with a soft brush, and then a mixture of castor oil and alcohol dabbed on with a soft brush, and removed by diluting with turpentine and sopping up with a large dry brush. Where alcohol is not a sufficiently powerful solvent, copaiba balsam emulsified with ammonia might be used, a preparation of copaiba balsam thinned with a little turpentine being laid on the surface first. If any friction is to be applied it should be done with a soft rubber point, and at every stage examined under a powerful magnifying glass.

Correspondence.

*** *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

*** *We do not undertake responsibility for the opinions expressed by our correspondents.*

THE MANIPULATION OF MATT EMULSION PLATES.

To the Editors.

Gentlemen,—As the leading manufacturers of matt-emulsion plates we are interested in your correspondent's communication of last week, relative to the refusal of the matt-emulsion plates to adhere to the support after abrasion.

Contrary to the finding of Mr. A. B. Thomas, no difficulty has been experienced in this direction, the film adhering as easily as in

the case of the non-matted plates, even after treatment with either a hardening bath or immersion in spirit.

Possibly further information may be forthcoming as to the treatment the negative was subjected to, rendering the film non-adhesive under the conditions stated.

The defect, however, can be made good by removing a section of film of like density, from a discarded negative, and, after moistening and dissolving the gelatine, "stippling" on with a "spotting" brush in the usual manner.—Yours faithfully,

ELLIOTT & SONS, LTD.
(F. E. Greenwood, Director).

Barnet, Herts, December 18.

WHAT IS PICTORIALISM?

To the Editors.

Gentlemen,—Mr. Tilney's comments on my Westminster Abbey exhibit rouse a desire to srgufy. The question comes up at once: What, then, do these self-styled Pictorialists mean by "Pictorial?" In his praise of Dr. White's prints, Mr. Tilney seems to be attaching a virtue to what was the chief failing of that time, the mostly inescapable fault of under-exposure. I cannot but feel that if Dr. White had had our plates and developers he would have made his sometimes fine subjects far more akin to the real genius of photography, the charm of full gradation.

Mr. Tilney says, "So Velasquez looked upon his subjects." But Mr. Tilney knows as well as I do that though Velasquez was a superb master of mass and tone, yet when detail was called for he was meticulously accurate and painstaking; look at any of his portraits to prove that.

Mr. Lewis Hind, so says your reporter, was of the opinion that "no painter would give results such as these," referring to my Abbey prints then on the walls during his lecture. If he had said "could" instead of "would," I might have agreed with him! But has Mr. Hind forgotten Turner's early architectural water-colour drawing, or the oil paintings of cathedral interiors by Bosboom and others? What did these "artists" set out to do? They selected a composition that appealed to them, drew it with the utmost care and accuracy in perspective and detail, and gave it what they considered the colours that best expressed it. The only point on which they differ from myself is that they often included far more in their composition than we can; if we used wide-angled (or short-focus) lenses to make their subjects we should get distortion, because we cannot get sufficiently far away; they could imagine the wall behind them to be non-existent, we cannot! Otherwise, except for colour, their procedure is mine exactly; choose a composition, select the hour of lighting that best exhibits it, and then render it in monochrome so that it recalls the original perfectly.

Mr. Tilney says I speak of my prints as "pictures," but that "the elements of pictorialism do not lie very much on the road Mr Evans has chosen in these views." Rather a cryptic utterance, again suggesting the "What then *is* Pictorialism?" I object to the words "record" or "view" as applied to my studies, because they seem to imply something inferior to the creative art of the painter or other artist. But are they? What I mean by a picture in the Abbey is the searching after that aspect of a specially chosen composition that most fully reveals its charm. Each of my studies were possible, were visible, only in the particular hour and kind of lighting that I discovered them in. They are therefore personal to me; no haphazard visit of any other photographer would elicit them. The ordinary visitor does not study, and I do not believe that either Mr. Tilney or Mr. Hind had studied the Abbey at every hour in every kind of lighting to see where the pictures exist. I did; therefore my personal expression of them amounts to creative art—or else what *is* creative art? It is, of course, this revealment, this evocation, by the artist that constitutes picture-making. But because the methods or the results are of a kind or style that these critics or pictorialists would not have made for themselves, they deny the title of "picture" and dub them only records, or representations, or views. But there are countless styles and kinds of picture-making; and the final test is, is the result beautiful, does it ennoble, does it reveal the underlying meaning of the subject, does it evoke the real spirit of the place, does it convey the feeling that it is a personal expression of the worker? If it does, then it matters not whether it is by etching, water-colour, oils, pastels, or by camera. Look through the guide and other books issued year by year on the Abbey—full of "records," "views," never a picture or personal expression in them, any camera by any worker could make them. Does Mr. Tilney class mine with them, only, perhaps, superior in technique or tone rendering?

The camera can do things in the way of light rendering, of subtle gradations of tone, of atmosphere, and in purity of line, detail, texture, that no hand art can excel. It may also have a breadth of expression, a sense of vision, of equal value to hand art; the fact that this is less evident in photography than in hand art only proves that camera workers have amongst them fewer men capable of such vision, or of giving expression to it.

Mr. Tilney says "the pictorial charm of the Abbey is in the very gloom that Mr. Evans dissipates" by his "fetish of exposing for the shadows." I should have thought that the most perfunctory examination of my prints would have shown that the "gloom" was the chief thing I had properly exhibited, not as blank, black nothingness, but with its living depth and wonderful gradation. Gloom is always resolvable to the eye; the grading and detail always come out if patiently studied, and the perfect photograph, or any other rendering, is that which gives the result of this patient study, not the hasty generalised impression of its being merely a dark place. Apparently, however, under-exposure is to be the key to the problems of picture-making. (What *would* Mr. Tilney say if the next Salon or R.P.S. shows were full of subjects as badly treated technically as Dr. White's are!). New rule: Do *not* expose for the shadows, that is only an Evans' fetish; go for black, empty, meaningless spaces with no play of light or depth in them, and there's your picture!

Mr. Tilney compliments me on the historical, architectural and archæological value of my prints. But that is just what I practically ignored or neglected. I do not care a dump what period the building is of, and its history might be non-existent for all I should care; what I wanted to do was to show what the Abbey meant for me, in its extraordinary range of richness of gloom, of light, of atmosphere, its elegance of composition, etc.; to show how human these old builders were, and how full of beautiful ideas they were, what picture-making they aimed at in their aisles, crossings, chapel entrances, etc. If to reveal something of all this is to make "records" only, to be ignorant of Art or incapable of picture-making—well, one is in good company, for Turner, Bosboom, and all the rest of them come under the same ban in similar subjects.

Mr. Tilney says I *admitted* (I didn't know I was on my defence!) that a certain tomb was in darkness, but that I have shown it as transfigured by a lightning flash. (I am glad he did not say "flash light," the effect I particularly loathe for its crude hardness.) What I said was that that particular tomb was black with age, and is so placed that its fine sculptural ornamentation can only dimly be seen, except at one hour, when a side light reaches it, and then its sculptured detail is delightfully visible with the darkness of its shadows so reduced that the tomb is seen in much the condition its maker saw it in. Surely it would be mere madness for an artist not to "record" it in its proper and most favourable lighting. To depict it as a mere dark mass with scarcely a hint of its sculptured detail would be senselessly inartistic.

I would like Mr. Tilney to look—I think he *must* have missed it before—at my version of the tomb of the Buckinghams. As I told the meeting, this was an impossible subject, because of a white glass window staring into the lens from behind the tomb. But by careful sky-shade use and making the frame of the door of the chapel help cut off the window, I secured a rendering of the tomb with its figures well lit up, but all other details submerged, and only the radiance from the window as a background. If this is not creative picture-making, what on earth is it? I made it; it does not exist except in my platinotype print.

Mr. Tilney says "as soon as the enchanted beholder adjusts his vision from the broad responsiveness to the acute searching of detail he has finished with the picture." Not necessarily or wholly, even in the beholder, and certainly not with the artist who depicts it. He must do both, convey the "thrilling play of darkness and light" *with* a commensurate rendering of its details (unless he is working with pen and ink devoid of shading), or else the full picture message will not be delivered. I will cheerfully and confidently refer Mr. Tilney to my print, "South Transept into Aisle and Nave," as an example of this. It is an effect I saw but once in the Abbey in that intensity, and as I pointed out to the meeting it is a good instance of the handicap that photography suffers under and prevents it ever having the complete freedom of hand art. The gloom of the Abbey was intense that day, but was irradiated in aisle and in nave by shafts of sunlight on their walls. If that sunlight had not lasted long enough to render a full exposure possible (under-exposure would have been blue ruin only), the picture would not have been caught. A painter might by a rapid sketch have memorised the effect for after working up. Even our glorified "faking" could not do that. But I did get it, and there it is, as

fine an example of "thrilling play of darkness and light" as I have ever made or hope to. It must be going on for a quarter of a century since my friendship with F. C. T. began, so I can the more gamely now adjure him to "come on!"

FREDERICK H. EVANS.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

T B.—The firm for Heliolettes is now Messrs. Jefferies & Co., Ltd., Pembroke House, High Road, Seven Kings, Essex.

BLUE PRINTING.—The book you mention is "Ferric and Heliographic Processes," by G. E. Brown, now out of print, but possibly obtainable from Messrs. W. & G. Foyle, Ltd., 121/125, Charing Cross Road, London, W.C.2.

A. O.—The trouble is entirely due to the rusty conditions of the dishes. We should advise you to discard these altogether and use either wooden or xylonite dishes in their place. Painting and enamelling the old dishes would be useless.

J. S.—The stain occurs in the film of the plate owing to its extra thickness, but we think you may easily remedy this by adding, say, 5 per cent. extra sulphite. More bromide would give greater contrast, and this, we take it, you do not want.

REFLEX.—We should say the spring controlling the blind has become weak and requires renewing. You should send the camera to Messrs. Peeling and Van Neck, Ltd., 4-6, Holborn Circus, London, E.C.1. This firm makes a specialty of focal-plane shutter repairs.

X. M.—The lens would be most suitable for studio work, especially large heads, but it would not be better than the anastigmat for groups. We should choose the latter under your conditions, as the lens is apparently required more for commercial work than portraiture.

M. V. R.—If the print refuses to ink, we should imagine it has been soaked in water of too high a temperature. It would be best to dry the print and then re-soak in water at a much lower temperature. The opposite applies if the print takes ink all over, but this may also be due to either unsuitable paper or bleaching bath.

PRO.—(1) Lithographic ink may be used, but it is necessary to have some little experience of the process before the best results may be obtained with this substance. (2) The Bromoil brushes supplied by Messrs. J. A. Sinclair & Co., Ltd., 54, Haymarket, London, S.W.1, are most suitable. (3) No; stencil brushes are useless.

J. T.—The general lay-out of your dark room seems quite satisfactory. Certainly, the window should be fitted with a blind moving in grooves. Messrs. James A. Sinclair & Co., Ltd., 54, Haymarket, London, S.W.1, make such a fitting which allows the room to be instantly converted into a dark room by merely pulling the blind.

S. E. E.—Yes, it is quite possible to place a colour filter in the front of the spotlight: in fact, the makers of these lamps supply various filters mounted in frames which fit the grooves in front of the lamp. A yellow filter could be used when working with panchromatic plates, but we do not see how the exposure could be any less than if a filter was placed in front of the lens.

L. S.—The trouble is due to some object which was in front or behind the lens during exposure. As you are getting the patch of lesser density in each exposure, we should advise you to examine the inside of your camera. We believe the trouble will be found to be due to a portion of the material of the bellows which has frayed out and is in the path of the light from the lens.

C. R. E.—The type of photograph you mention may be easily produced by means of a pinhole. A box is taken, capable of holding a plate, of the size with which it is intended to work, in an upright position, about 2 inches from one end. At this end the pinhole lens should be fixed. If you then place the pinhole about 6 inches from the sitter's face and give sufficient exposure you will get the effect you desire.

C. B.—A good method is to first fog a dry plate and develop it to an even tint of grey, then fix, wash and dry. This is then placed in a printing frame in the dark room and a slow plate placed in contact. Exposures are then made to candle-light at about 6 inches distance, commencing at, say, 2 seconds and increasing in any known ratio until the 12 strips are exposed. The exposed plate is then developed in a clean non-staining developer.

M. B.—Matt varnish may be made as follows:—

Sandarac	90 grs.
Mastic	20 grs.
Ether (0.720)	2 ozs.

Dissolve the resins in the ether and afterwards add:—

Benzole	¼ to 1½ ozs.

The quantity of the benzole added determines the nature of matt effect obtained. Apply the varnish cold to the glass side of the negative.

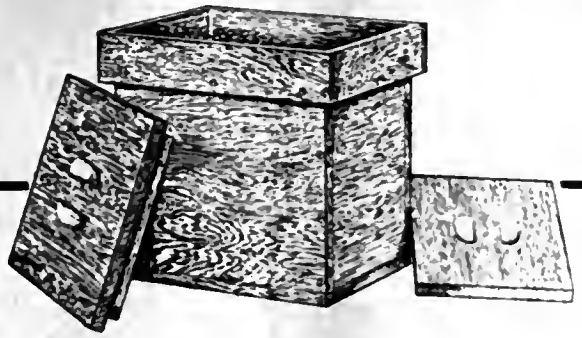
COLOUR.—Yellow or three-colour filters are supplied in gelatine by all the leading makers, including Messrs. Ilford, Ltd. These filters, when cut to size, may be placed in the tube of the lens between the components. We think, however, it would be better to obtain the three-colour filters in optical flats, as you will find a difficulty in changing the gelatine circles between each exposure. If you send the measurement of the outside diameter of your lens hood when ordering the filters, the makers will supply the filters in cells which will fit.

P. L.—Hydroquinone accelerated with caustic soda is the best developer for obtaining contrasty results. If the plates are over-exposed, double the quantity of potass bromide.

A. Hydroquinone	160 grs.
Sodium sulphite	2 ozs.
Citric acid	60 grs.
Potass bromide	40 grs.
Water to	20 ozs.
B. Caustic soda (stick)	160 grs.
Water to	20 ozs.

For use take: A, 1 oz.; B, 1 oz.; water, 2 ozs.

The temperature of the developer should not be allowed to fall below 60 deg. F., or the solution becomes inert.



Eastman Portrait Film Developing Tanks

Teak Developing Tanks will enable you to develop your films more quickly and economically than you can with the old fashioned dish method. Tank development gives you clean, crisp negatives, free from finger marks and scratches. Eastman Portrait Film Tanks are coated inside with an acid-resisting preparation. They are strongly made of well seasoned teak. They are exceedingly durable and.... but read what Mr. James A. Hamilton says about the Teak Developing Tanks.

CLYDE STUDIO,
11, Broad St.,
Staple Hill,
Nr. Bristol.

James A. Hamilton,
Artist & Photographer.

To Kodak Limited,
Kingway, W.C. 2.

Dear Sirs,

In respect to the Film Developing Tank you sent me for trial, I must say I am more than delighted with it. I have been all my life in the photographic business—born in it, been 26 years on my own account, and had never tried Tank development before, and *I shall never go back to dish.* It is so clean and certain. I came to grief a little at first by either over or under-development, but now I am getting splendid negatives and no trouble. I must thank you for inducing me to try it—it is splendid.

(Signed) J. A. HAMILTON.

Size No. 2. Capacity—Eight 6½ × 4¾ in., or 5½ × 3½ in., or 4¼ × 3¼ in. Tank only **19/-**. Cover **6/6**. Floating Lid **2/-**.

Size No. 3. Capacity—Twenty 6½ × 4¾ in., or 5½ × 3½ in., or twelve 10 × 8 in., or 8½ × 6½ in. Tank only **£1 6 6**. Cover **9/-**. Floating lid **3/-**.

Size No. 4. Capacity—Twenty-five up to half plate or fourteen 12 × 10 in., or 10 × 8 in., or 8½ × 6½ in. Tank only **£2 0 0**. Cover **11/3**. Floating lid **4/3**.

Kingsway, W.C. 2.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3269. Vol. LXIX. FRIDAY, DECEMBER 29, 1922. Price Fourpence.

Contents.

SUMMARY.

The Index to the 1922 volume of the "British Journal," and to that of the "Colour Photography" Supplement, is presented as a supplement to this issue.

Mr. A. H. Hall has made systematic experiments on the effect of the possible variations in the working of the Carbro process upon the character of the prints as regards tone rendering. (P. 783.)

MM. A. & L. Lumière and A. Seyewetz have made experiments on other quinone compounds for intensification of negatives and toning of prints and transparencies, and have found that halogenated quinones behave like benzoquinone and that toluquinone is the best further compound for toning. (P. 785.)

Some notes on the making of enlargements in colour as a sideline in the trade of developing and printing for amateurs are contributed by Thermit. (P. 785.)

The report of the committee appointed by the Board of Trade, under the Safeguarding of Industries Act to hear a complaint respecting the sale of cameras, photographic lenses and other goods of German manufacture, was published on Friday last, December 22. So far as concerns cameras and lenses, the committee have expressed the opinion that the applicants' evidence was insufficient to show that these goods are being sold in Great Britain at prices lower than those at which they can be profitably manufactured in this country. The parts of the report which relate to cameras and lenses are reprinted on pages 786-788, and will be found to contain some interesting official statistics respecting the importation of cameras during the past two or three years.

In a note on page 781 we refer to the official machinery provided in the Safeguarding of Industries Act for the making of a "complaint" in respect to goods which, it is alleged, are being "dumped" into this country.

In a leading article we offer some suggestions to professional portraitists on the personal manner which helps towards the making of characteristic likenesses of their sitters. (P. 782.)

In the King's Bench Division of the High Court last week judgment was given in a case of copyright infringement (of a musical work), when it was held that the authorising of performance of the music constituted infringement, even though the "authorising" consisted in neglect to prevent the performance. The judgment will be found on page 790, and our comment upon it on page 781.

Cleaning originals before copying, and the making of a novel plate-rack, are the subjects of "Assistants' Notes." (P. 788.)

For the cleaning of Bromoil brushes, and also for removing the pigmentation from a Bromoil print, carbon tetrachloride is much to be preferred to petrol. (P. 782.)

Mr. J. B. Payne has retired from the chairmanship of Mawson & Swan, after a connection with the photographic industry of more than sixty years. (P. 791.)

Croydon was in a Christmassy mood last week in finding analogies to emulsion constants. (P. 789.)

EX CATHEDRA.

Copyright Infringement by Authorising

In delivering judgment last week in the High Court respecting an action for infringement of the copyright in certain musical works, Mr. Justice Rowlatt had to lay emphasis upon a passage in the Copyright Act on which, so far as we remember, a case has not turned; at any rate, not a photographic case, although the circumstances might easily arise in connection with photographs. The passage is the last line of Section I (2) of the Copyright Act, which provides that the authorisation of any of the Acts which are an infringement of copyright is itself an infringement of the copyright. The case before the Court was that of a firm of theatrical producers who had been sued by the owners of rights in respect to the unlicensed performance of certain music between the acts of a play. One of the defendants was managing director of the theatrical producing firm, and in that capacity was responsible for the music which was played in the intervals of the performance. Apparently, the fact that he did not prevent the performance of the copyright music (it was the conductor of the orchestra who selected it) is held in law to be equivalent to his having authorised its performance. The judgment has an obvious application to cases which could easily arise in the reproduction of photographs, as, for example, those in which a person authorises the reproduction of a photograph of which he does not hold the copyright. It has long been recognised that a person who definitely orders a work to be reproduced is equally liable, as regards infringement, with the actual copyists. The passage in the 1911 Act, to which we have referred above, states this provision in a somewhat different way, whilst the judgment of last week serves to show the wide meaning which may be given to "authorise."

* * *

German Scientific Goods.

The Report has just been published of the Committee appointed by the Board of Trade in May last for inquiry into a complaint respecting the sale in this country of optical and other scientific instruments, including cameras and photographic lenses, manufactured in Germany. On another page we print the parts of this Report which relate particularly to photographic goods. Here, it may be of service to point out that Part II. of the much-discussed Safeguarding of Industries Act provides certain machinery for the purpose of preventing the "dumping" of foreign goods into this country. According to Section 2 (1) a "complaint" can be made to the Board of Trade that, in the opinion of the complainant, goods are being sold in this country (*a*) at prices below the cost of production, or (*b*) at prices which are below those at which the goods can be profitably manufactured here owing to depreciation of the currency of the country of origin; and further, that from one or other of these

causes employment in the respective industry in the United Kingdom is seriously affected. Taking advantage of this provision, several trade associations, among them those connected with the manufacture of photographic and optical apparatus, lodged a "complaint," whereupon the Board of Trade followed the course laid down in the Act, namely, of appointing an independent committee to hear the evidence of the complainants and that of any opponents. As will be seen from the Report no evidence was submited by the complainants regarding cost of production in Germany. On the alternative question, the Committee's Report is that the evidence respecting cameras and photographic lenses was insufficient to convince them that the German articles "are being sold or offered for sale generally or on a commercial scale in the United Kingdom at prices below those at which similar goods can be profitably manufactured in this country." While pointing out that their report was presented at a time (July last) when German currency stood at about 2,300 marks per £ sterling, they particularly emphasise, in regard to cameras, that the number imported from Germany is only a small proportion of the total trade of the United Kingdom in these goods, a view which they support from the official Customs statistics presented in tabular form in the Report.

* * *

Cleaning Bromoil Brushes. The technique of the Bromoil process has made great strides recently, and much of its uncertainty has been overcome by careful experiment. The literature of Bromoil has accordingly grown rapidly, but not much has been said about some of the minor, but still important, details of the process. Among other items, when the process was introduced, petrol was recommended for brush cleaning, and that is still the case now. Petrol has one or two drawbacks in use—it is never quite free from greasy substances, and therefore leaves a greasy deposit in the brushes after it has itself evaporated; and although this deposit may be small, it is sometimes enough to interfere with inking when the brushes are next used. Petrol is also very inflammable. A liquid which evaporates much more completely, and which refuses to take fire, is carbon tetrachloride. The name is admittedly more formidable than petrol, and local dealers may be found unfamiliar with the substance. It is, however, readily obtainable from large chemical dealers and sundriesmen, and its price is quite reasonable. The use of carbon tetrachloride is not confined to brush cleaning. It may be used with equal satisfaction for removing the ink from a Bromoil which is unsatisfactory; and it is also a perfect substitute for petrol for removing grease spots from clothing.

* * *

Bleach Prints. The aid of the photographer is very often called upon by the commercial artist or draughtsman to make prints, either of articles or of existing drawings, to specific sizes, in order that they may form part of a "lay-out." In other cases the print is merely used as a basis for a line-drawing in waterproof ink, the photographic image being dissolved away when the main work has been done. A photographer who has a convenient copying arrangement, and whose premises are in a strictly commercial neighbourhood, can make a very useful side-line of this work, but there are individual likes and dislikes among artists that should be studied if the work is to be profitable. The principal consideration may be summed up in the familiar slogan of the engraving and printing trades, "Time is the essence of this contract." Some artists like to make their line drawings upon a tracing linen or paper pinned over the photograph, instead of utilising the bleach-out method; in such cases obviously a vigorous print somewhat on the dark side is indicated. On the other hand, for the majority who still prefer the bleach method, an over-exposed print, developed in a diluted and restrained solution giving a weak greeny-grey result, will be the best, as the hand work will show up much more clearly as it progresses than upon a normal bromide print. Such a print bleaches out in the iodine bath in a very few seconds, and there is less for the subsequent fixing bath of cyanide to remove.

EXPRESSION IN PORTRAITURE.

If we except those sitters whose only desire is for a "pretty" portrait, we shall find that the great desideratum is a portrait with a pleasing or, perhaps, more correctly, a characteristic expression. More than one well-known portraitist can tell of sitters who, after he has expended the utmost of his skill upon them without success, have produced a snap-shot print and asked whether it could be enlarged and finished, because "it was the best portrait they ever had." Such happenings give food for thought on the part of the portrait artist, as to the way to avoid such humiliation in the future.

We should hardly like to refer to the oft-quoted story of Sir Joshua Reynolds, in which he is said to have wished to dine with a sitter before painting his portrait, did it not convey such an obvious lesson to anyone engaged in portraiture by any method. Here the painter wished to study his model at his leisure, carefully noting any little mannerisms, and particularly his expression, at the most favourable moments, so that the actual sittings were more devoted to drawing than to the study of expression, which was at this stage often marred by self-consciousness.

The photographer is in a much less favourable position than the painter, because not only has he less time to take stock of his sitter, but he has no opportunity of modifying his work as it goes on. It is just a question of an exposure of a few seconds at the psychological moment, and success in these circumstances calls for a combination of qualities which are rarely found in human nature.

Every class of society has its own peculiar amenities, and the methods which are suitable for one are out of place with another. Still, there are certain attributes which may be considered as general to operators of all classes, and we cannot do better than endorse the advice of Shakespeare to "assume a virtue though you have it not." Long experience teaches that in the vast majority of cases the sitter is a faithful mirror of the operator. If the latter be fussy and inclined to be irritable; if he be slow and self-absorbed; if he be unduly obsequious, or on the other hand arbitrary or overbearing, these will certainly have a deleterious influence upon the sitter. If, on the contrary, the operator be vivacious without being boisterous, courtly without being servile, and well informed upon such matters as are likely to interest his client, the latter is placed at his ease, and is likely to assume an expression which will be acceptable to his friends.

The arts which evolve a favourable expression must be carefully concealed from the sitter, or they will fail, and particularly is an excess of words to be avoided. We have heard operators of both sexes who have cackled (there is no other word for it) to the sitter during the actual exposure, and the worst of it was that the cackle was not even intelligent, attempts at sporting talk being on the level of Ouida, who described her hero as pulling two strokes to every one of the rest of the crew in a

'Varsity boat race. It is the experience of most successful workers that the less said during the actual process of posing and exposing the better, if the sitter can be put *en rapport* with the photographer at an earlier stage. A few words of appreciation, real or simulated, will often work wonders in securing a satisfactory expression, but these should only be uttered a moment or so before the bulb is pressed. Such sentences seem trite in print, but they are effective at the moment. A remark that there is a beautiful light upon the hair, gives rise to the idea in the sitter's mind that her hair must be beautiful, and the portrait reflects the "flattering unction" which has been laid upon the soul. It is surprising how much indirect flattery can be used, upon both sexes, without detection, and, indeed, how much direct flattery too, if there is no one else in the studio to hear it.

The great pitfall to be avoided is undue familiarity, and it is very difficult to say at what point this commences, so much depending upon the personality of the operator. What may be said without offence by a dignified veteran becomes unpardonable in the mouth of a man in the thirties, because it is assumed that the one is speaking from long experience and as an artist only, while the other is giving his personal opinion as a man.

Could we mention names we could give instances of failures which have been entirely due to an unfortunate personal manner on the part of the photographer, which has rendered the highest skill and the most unflagging industry worthless, while, on the other hand, a very moderate amount of photographic ability joined to a pleasing manner has spelled success. The public will endure faulty technique, bad posing, and almost any other artistic fault, but they will not forgive a bad expression, hence the success of the snapshot. It is well to remember this when tempted to spend too much time in arranging drapery or altering the pose, as it is so easy to weary the sitter and so lose all prospect of getting a good expression.

Brief mention must be made of the influence of the surroundings in the studio and reception room upon the sitter. Scrupulous cleanliness, well-chosen ornaments and furniture, fresh and healthy flowers and plants, all play an important part in producing a pleasing impression on the mind of the client, and no studio is too humble to be able to disregard this hint.

EXPERIMENTS ON CONTROL IN CARBRO PRINTING.

The writer is of opinion that there is no method of printing which gives such fine results to the worker who confines himself to a hand camera, and consequently uses small plates, as the Carbro process, unless, of course, he is prepared for the trouble of enlarged negatives and contact prints. In the course of making a considerable number of prints by this process certain results were obtained which did not quite fit in with what was expected; the number of variables which occur between the commencement of operations and the finished print make it difficult to determine what is exactly the cause of any particular variation. It was therefore decided to carry out a series of systematic experiments, altering one variable at a time, and to tabulate the results.

To eliminate one variable at the start, the question of the No. 2 solution is worth consideration. Early experiments with formaline purchased fortuitously gave good results, but the time of immersion in the solution with different samples was variable and longer than with the materials supplied by the Autotype Co. The druggist supplies formaline presumed to be B.P. strength, i.e., 36—38 per cent., but it appears to be rather a variable quantity. The solution shown in Table 2 was known to be out of a new stock, and the results are similar to those with Autotype solution. To eliminate this variable, however, it appears advisable to buy the solution from the source.

The method adopted was to take a certain number of prints, cut them in pieces, and take Carbros off each piece. When dry the margins were cut off and the parts pieced together, as it is considered that this method enables slight variations in density and contrast to be readily detected. As a species of cross check some of the later experiments were conducted with pieces of the earlier bromides; when finished, as will be seen from the notes at the bottom of the tables, these pieces fitted in with the earlier prints extremely well.

The writer is not possessed of a laboratory, but the conditions were certainly kept as constant as will usually be found in everyday working; the temperature of the room was carefully measured each time, and did not vary more than 5 degrees, the range being 60 deg. F. to 65 deg. F., and the temperature of the solutions varied to a somewhat less extent, certainly not more. As the temperature of the developing water has a considerable effect on the depth of the print, great care was taken to have a good volume and start operations on each print at exactly 91 deg. F. As soon as the backing was stripped, steps were taken, by agitating the print and by pouring water on to it, to remove all the freely soluble gelatine and pigment as quickly as possible. As soon as the print was clear it was rinsed in cold water and placed in the alum bath. No attempt, of course, was made by prolonged immersion, or by the use of hotter water, to lighten a test piece which would normally be considered too dark, nor were contiguous pieces off one bromide compared until they were ready for drying.

It did not appear useful to vary the time of immersion of the tissue in No. 1 bath, as it should be saturated with solution.

The places where variations might occur were:—

(1) Time of immersion in No. 2 bath.
(2) Strength of No. 2 bath.
(3) Time of contact with bromide print.
(4) Time of contact with transfer paper before development.

The tables below give the results, while the notes on the tables refer to the cross checks previously mentioned.

VARYING TIME OF IMMERSION IN No. 2 BATH.

Constants (1) Time of contact with bromide, 15 minutes.
(3) " " transfer paper, 30 minutes.

No. of print.	Make of paper.	Type of print.	Time of immersion (secs.).	Appearance of bromide print after contact.	Result.
1	Illingworth	Normal, no heavy shadow	0	Completely bleached	All half-tones washed up.
2	"	"	5	"	A good deal of washing up.
3	"	"	10	"	Correct.
4	"	"	15	"	"
5	"	"	20	"	"
6	"	"	25	"	"
7	Wellington	Strong, rather heavy print	10	Darker portions unbleached	"
8	"	"	20	As No. 7.	"
9	"	"	30	A considerable portion of print unbleached.	Distinctly flatter, less depth in the shallows.
10	Vitegas, bleached and re-developed.	Strong, heavy print.	15	Completely bleached.	Correct.
11	"	"	30	"	"

VARYING STRENGTH OF NO. 2 BATH.

Constants: Time of contact with bromide, 15 minutes.
" " transfer paper, 30 minutes.

No. of Print.	Make of paper.	Type of print.	Strength of solution.	Time of immersion (secs.).	Remarks.
12	Illingworth.	Normal.	A, normal strength.	15	All four pieces joined up without much difference in density and contrast. The quality of 12 and 13 was apparently slightly better than 14 and 15.
13	"	"	B, normal strength.	15	
14	"	"	B, half strength.	30	
15	"	"	B, quarter strength.	60	

NOTE.—A solution is Autotype Co.'s make.
B solution contains formaline B.P. strength, purchased from a druggist.

VARYING TIME OF CONTACT OF TISSUE AND BROMIDE.

Constant: Time of contact with transfer paper, 30 minutes.

No. of Print.	Make of paper.	Type of print.	Time of immersion. (secs.).	Time of contact. (mins.).	Remarks.
16	Illingworth.	Normal.	15	22½	No effect.
17	Wellington.	Strong print.	30	22½	Full depth.
18	"	"	30	10	"
19	"	"	30	5	"

NOTE.—No. 16 is part of print represented by 20, 21, 22; the four pieces join up together well.
No. 19 is a duplicate of 25, and both are of the same depth; the same applies to 18 and 24.
Nos. 18 and 19 show a trifle more contrast than 24 and 25; there was not much difference in the amount of bleaching between 17, 18, and 19, 17 was rather more bleached; but the results were clearly not proportional to the time.

VARYING TIME OF CONTACT OF TISSUE AND TRANSFER PAPER.

Constants: Time of contact with bromide, 15 minutes.
Temperature of development, 94° F.

No. of print.	Make of paper.	Type of print.	Time of immersion in No. 2 (secs.).	Time of contact. (mins.).	Remarks.
20	Illingworth.	Normal.	15	30	Normal.
21	"	"	15	50	"
22	"	"	15	60	"
23	"	"	15	12	"
24	Wellington.	Strong print.	30	12	"
25	"	"	30	60	"

No. 23 is a duplicate off the same piece of bromide as No. 4, and joins up well with 3, 5, 6.

The general trend of the results was a little unexpected. It was known that Illingworth's paper in normal working required less time in No. 2 bath than Wellington's, and the appearance of the bromide print when stripped from the pigmented paper is interesting.

In every case with Illingworth's paper (the prints were not very dark) the print was completely bleached, and the results tend to show that, given complete bleaching, none of the variations attempted has any effect on the ultimate result. Alternatively, there is not much object in continuing contact between the bromide and the tissue when bleaching has become complete.

With Wellington paper the prints used were rather dark. Some black was always apparent on stripping, and where the times of immersion in the No. 2 bath were long the amount of bleaching was less than where it was short.

This only confirms the published directions that short immersion gives depth and long immersion gives flatness, but with this limitation that it is not possible to increase depth over that which would be obtained as a straight transcript from the bromide, though some control in lessening the depth is possible.

It was not anticipated that so short a period as five minutes in contact with the bromide would give full depth, though the print was a dark one to start with. Further experiments with Illingworth paper gave results which were a trifle too light. It appears better, as stated below, to adhere to the standard fifteen minutes.

Another practical point which was clearly shown in these trials is that a print on black tissue looks slightly darker than one of brown colour, and this might be useful if a print was required from a rather light bromide.

The increased length of time between putting the tissue on the transfer paper and development did not, as is generally supposed, require hotter water. The time which elapsed before it was safe to strip the backing was certainly longer, but this may well be due to the tissue having dried somewhat more; there was no difficulty in developing a print, which had received sixty minutes' contact, with water at 94 deg. F.

In the writer's opinion, therefore, the amount of control possible by a long contact with the transfer paper is very small, the extra depth, if any, which could be obtained by this means is nothing more than could easily be washed off by hotter water without fear of blisters. Possibly a longer contact than one hour might have had some further effect.

It is therefore considered that the best method of procedure is to standardise the length of immersion in No. 2 bath at twenty seconds, with fifteen minutes' contact with the bromide, and thirty minutes' contact with the transfer paper, and make the bromide of such a depth that on stripping it will be found to have just a trace of black in the shadows.

This means that a print on Illingworth's bromide paper should be very considerably darker than on Wellington's; in fact, it should be a trifle darker than would be required for sulphide toning, while the Wellington print should not be darker than normal; if anything a shade lighter.

It is not advisable to make darker prints than described, as an increased time in No. 2 bath tends to impair the depth in the shadows, so that the beauty of the process is lost.

It may be useful to state the experience with various makes of bromide paper which have been tried:—With Kosmos, Criterion, Kodak, a good rich print a trifle darker than on Wellington is necessary. Paget should be half-way between Wellington and Illingworth.

Vitegas and Vittex Gevaert (after bleaching and re-development) require a print as dark as Illingworth's. All the above refer to matt papers; the semi-matt in the writer's hands have given considerable trouble with uneven patches.

Generally the best method is to have the right bromide for the particular paper used, to standardise the times, and rely on hot water for control, except in the case of very hard prints, when the time of immersion in the No. 2 bath can be increased somewhat.

A. H. HALL.

QUINONE COMPOUNDS IN INTENSIFICATION AND TONING.

IN preceding papers* we have shown that the remarkable oxidising properties of benzoquinone may be employed for the reduction of silver images, by using a solution containing sulphuric acid, and also for the intensification of negatives and toning of transparencies and prints by compounding the benzoquinone with a bromide or chloride. The theory of these actions, which appears most probable, has been outlined; and the properties which we have described have already been found of some service in photographic processes.

In the course of further experiments we have endeavoured

* "B.J.," 1910, August 19, p. 625, and December 16, p. 949; 1921, January 7, p. 6. For other references, see "B.J.," 1921, February 11, p. 74.

to ascertain if the above properties are peculiar to benzoquinone, or if they are exhibited by various bodies containing the quinone group, such as chloro, bromo, and sulphonated quinones and higher homologues.

Our experiments were carried out with monochlorquinone and its sulphonate, dichlorquinone, monobromquinone, and its sulphonate, toluquinone, naphthoquinone and anthraquinone.

The naphthoquinone, and also anthraquinone, used with sulphuric acid or with addition of bromide or chloride, exert no appreciable action upon the silver image; the other quinone compounds act very similarly to benzoquinone, although showing certain differences. The sulphonic derivatives (sodium salts), although possessing the advantage of more ready solubility, are not of practical interest, since they stain the medium and give results which in all cases are inferior to those obtained with the corresponding non-sulphonated quinone.

The chlor and brom quinones, with addition of an alkaline bromide or chloride, yield images which are more opaque than those obtained with non-halogenated quinones, probably because the chlorine or bromine in the compounds themselves form chloride and bromide of silver. This hypothesis appears to be confirmed by the fact, which is mentioned later in the present paper, that hypo reduces these images to a greater extent than those which have been bleached by a solution of a non-halogenated quinone.

The colour of the images and their degree of intensification vary according to the particular quinone which is used, but among the substances examined toluquinone alone was found to give results of substantial value for intensification or toning.

The degree of intensification which is given by toluquinone may not be equal to that yielded by benzoquinone, but, on the other hand, the intensified images are more transparent and of an agreeable purplish-red colour, of which advantage can be taken in the toning of transparencies.

The following is a comparative statement of the results obtained with benzoquinone, toluquinone, and chlorquinone, in conjunction with alkaline bromide for intensification of negatives and for the toning of transparencies and prints.

Intensification.

Benzoquinone. — Energetic intensification, brownish-red image, somewhat opaque, but toning to a dark brown in alkalis, sulphites, or bisulphites. Hypo reduces the toned image and increases its transparency without altering its colour.

Toluquinone.—Intensification somewhat less than with benzoquinone; transparent purplish-red image, with exceeding pure high-lights. The image is changed to a purplish-black by alkalis, sulphites and alkaline bisulphites. Hypo reduces the image without changing its colour.

Chlorquinone.—Intensification less than with benzoquinone, yielding an opaque image of yellowish-brown colour. Hypo greatly reduces the depth of this image, but does not alter its colour.

Toning.

The three preceding quinones produce very slight intensification of fine-grained images, and, in the toning of black transparencies, give the following results:—

Benzoquinone.—Transparent image of sepia-brown colour.

Toluquinone.—Transparent image of purple colour similar to that obtained by gold toning.

Chlorquinone.—Opaque image of reddish-brown colour.

The tones obtained on development papers correspond generally with those on transparencies, but the tones are not quite as bright, and the high-lights suffer a certain degree of tinting.

From our experiments, our general conclusion is that the property of benzoquinone of reducing, intensifying and toning silver images is possessed also by the halogenated quinones and by toluquinone. On the other hand, naphthoquinone and anthraquinone do not exhibit these properties. Among the various derivaties of benzoquinone, only toluquinone yields results of practical value, such as can be utilised for the toning of lantern slides, other transparencies on glass and cinema films.

A. and L. Lumière.
A. Seyewetz.

ENLARGEMENTS IN COLOUR.

For the establishment which depends to even a small extent on work for amateurs a line of coloured enlargements has big possibilities, and the present tranquility of business in general provides a good opportunity for launching a campaign of coloured work. The only requirement, over and above those of monochrome work, is the availability of someone with artistic skill, and if such a person is not on the usual staff, it is not difficult to get in touch with an artist who will do the work at home. In no case can the artistic skill be dispensed with, however. It is just as important for even the weakest pictures as it is for a good portrait, if the coloured line is to pay and do good.

There are different methods of colouring photographs, and as to which is best depends largely on one's taste and circumstances, while possibly the artist will be limited to a knowledge of one medium only. When there is no bias and different mediums are equally easy I would advise offering different styles at different prices, but for the best all-round single method I prefer the combination of water-colour and dye which was given in the "B.J." some time ago. This consists of painting practically everything but hands and faces in solid watercolour, and tinting the flesh with dyes. Very convincing results can be obtained in this manner, and from the hands of a good painter such work will have a "quality" appearance. For a cheaper line, dyes alone give very pleasing results, but a disadvantage of the dye method is that it appears too simple and does not always get the care that would be bestowed on opaque colouring. To look really well, dyes need more care, not less, than opaque colours, although a lesser degree of what I might call brush-technique is demanded with the transparent tints. Solid oils should fetch a higher price than water-colours, but personal taste often rules the comparative values of the two.

Unless small contact prints are included in the colouring schedule, coloured work will all be mounted, the tint of the mount being influenced by the quality of the colour. A pure white mount is probably the most suitable for a coloured picture, but mounts of any shade or tint may go with a picture which is not in a definite "tone" of painting. In the case of a monotone picture, the various tints of which are all within a cool or warm range (a seascape, for instance, showing nothing but blues and greens), a more restricted choice of mount is compulsory. A red mount on the seascape would be as upsetting as a green one on a firelit picture.

While it is in order to mount all coloured pictures, or, in other words, to offer nothing but mounted work, it is also easy to include framing or passe-partout, and so increase the monetary value of the work. Gilt is about the most popular thing for coloured pictures, and this can be obtained in passe-partout binding as well as moulding. A window show of well-coloured enlargements on fairly large white mounts in gilt passe-partout, makes a very attractive exhibit.

Whatever prices are decided upon, they should be well above those for similar pictures in monochrome. I recently saw a list on which the prices were over three times the black-and-white figures. As the actual cost of the colouring is not likely to be equal to the list price of the mounted uncoloured enlargement, a good profit was ensured by these figures, and though they seemed high, there was a fair demand. It is obviously possible to turn out good work at lower rates than these, but they must not be too low.

When framing and passe-partout are undertaken, the same principle should be applied. Frames can be bought for a shilling or so, but the making of a high-class frame to order is a different proposition. It does not pay a good firm to connect itself with shoddy stuff. The case is slightly different with passe-partout binding, as it is possible to get really first-class work in this line from the dealers at a very moderate figure, but I know one photgrapher who charges nearly double the usual prices, and does so successfully. My own plan is to double the cost of the materials and add 1s. per

picture: whatever the size, this method of pricing seems to give satisfaction all round.

It is, of course, simple enough to make a good display and offer a complete range of coloured work, without having recourse to framing of any kind, but the frame gives perfection and finality to a display. Framing will follow an order for a coloured enlargement as surely as the purchase of a stamp follows the writing of a letter, therefore it pays both photographer and customer to have the order finished completely at first.—THERMIT.

GERMAN SCIENTIFIC GOODS.

REPORT OF BOARD OF TRADE INQUIRY COMMITTEE.

ON Friday last, December 22, was published the report of the Committee of Inquiry appointed, under the Safeguarding of Industries Act, by the Board of Trade, to hear a "complaint" brought by several trade organisations, among which were the British Photographic Manufacturers' Association and the British Optical Instrument Makers' Association.

The Committee consisted of Sir R. Henry Rew, K.C.B. (Chairman), Mr. A. K. Davies, Mr. Rayner Goddard, Mr. A. E. Holmes and Mr. J. F. Mason, J.P., all of whom sign the report.

The instruction to the Committee was (1) to report whether the conditions specified in Section 2 (1) of the Safeguarding of Industries Act are fulfilled in respect of all or any particular varieties of optical and other scientific instruments. The conditions specified in this Section of the Act (which applies to the prevention of "dumping" into this country) are that the goods are sold or offered for sale at prices below the cost of production; or that by reason of depreciation of currency in the country of origin they are sold here at prices which are below those at which similar goods can be profitably manufactured in the United Kingdom; and that, in consequence of the above, employment in the particular industry in the United Kingdom is being, or is likely to be, seriously affected.

The Committee was also asked to report on the effect of the imposition of a duty under Part II. of the Act, and also was asked to express its opinion on the efficiency and economy with which the goods are manufactured in the United Kingdom.

The proceedings of the Committee were reported in the "British Journal" of May 19, 1922, pp. 298-299; June 9, 1922, pp. 342-343; and June 23, 1922, p. 371.

We print below those portions of the report which relate to cameras and photographic lenses, in addition to the general introduction and to the summary of conclusions. The portions omitted are those relating to microscopes, prism binoculars, ophthalmic lenses, and spectacle frames and eye-glass mountings, and mathematical drawing instruments.

To the

Right Hon STANLEY BALDWIN, M.P.,

President of the Board of Trade.

SIR,

1. By your original minute of appointment, dated 27th April, 1922, this Committee was constituted under Part II. of the Safeguarding of Industries Act, 1921, to inquire into a complaint by the British Optical Instrument Manufacturers' Association, Limited, the British Photographic Manufacturers' Association, the Spectacle Manufacturers' Association, and the Drawing Instrument Manufacturers' Association, that Optical and other Scientific Instruments manufactured in Germany are being sold or offered for sale in the United Kingdom at prices which, by reason of depreciation in the value in relation to sterling of German currency, are below the prices at which similar goods can be profitably manufactured in the United Kingdom, and that by reason thereof employment in the industry manufacturing similar goods in the United Kingdom is being, or is likely to be, seriously affected. We were directed, after ascertaining the facts, to report to the President of the Board of Trade—

(a) whether the conditions specified in Section 2, Sub-section (1) of the Safeguarding of Industries Act, 1921, are fulfilled in respect of all or any particular varieties of Optical and other Scientific Instruments;

(b) on the effect which the imposition of a duty under Part II. of the Act on goods of the class or description covered by the complaint would exert on employment in any other industry being an industry using goods of that class or description as material; and

(c) whether in the opinion of the Committee production in the industry manufacturing similar goods in the United Kingdom is being carried on with reasonable efficiency and economy.

2. The terms of reference to the Committee were published by the Board of Trade in the "London Gazette" of the 28th April, 1922 and it was announced that our first sitting for the taking of evidence would be held on the 15th May, 1922.

3. On the 16th May, 1922, the Board of Trade gave notice that our Terms of Reference were extended to include Optical Elements, whether finished or not, manufactured in Germany, and that the first sitting for the taking of evidence in regard to these additional articles would be held on the 31st May.

4. All the articles to which our inquiry relates (with the exception of spectacle frames and eye-glass mountings), are subject to a duty under Part I. of the Safeguarding of Industries Act, which came into force on 1st October, 1921.

5. The application was opposed by certain Wholesale and Distributing Houses and Export Merchants, and also on behalf of persons engaged in Scientific Research.

6. All the oral evidence was given in public and occupied four sittings of the Committee. In all, twenty witnesses were examined; ten persons, all of whom are concerned in the manufacture of articles to which the inquiry relates, gave evidence in support of the application. The opposition witnesses consisted of the General Secretary of the National Union of Scientific Workers, the Professor and Head of the Department of Chemical Technology at the Imperial College of Science and Technology, the President of the Electrical Wholesalers' Federation, and seven representatives of Importers, Wholesale Houses and Export Merchants. Both sides were represented by Counsel; Sir Arthur Colefax, K.C., and the Hon. R. Stafford Cripps (instructed by Messrs. Vizard, Oldham, Crowder and Cash) appeared for the Applicants, and Mr. T. W. H. Inskip, K.C., M.P., and Mr. Ernest Evans, M.P. (instructed by Messrs. Stikeman and Company) appeared for the Opponents.

7. The oral evidence was supplemented by a large number of specimens of instruments and articles which were handed in by the witnesses and by detailed statements of cost of production and other financial particulars which were supplied confidentially to the Committee.

CAMERAS.

24. No figures were submitted to us of the output of the whole of the camera-manufacturing industry of this country, but the representative of a large English firm of makers stated that at present their output of cameras is on the average about half that of 1913. Account, however, must be taken of the fact that the firm in question normally have a large export trade, and that this has decreased to, at present, about 20 per cent. of the pre-war amount. During the war, this firm, like others in the optical industry, concentrated on the output of apparatus needed for the conduct of the war, 90 per cent. of their plant being employed in the manufacture of special instruments. After the termination of hostilities the trade experienced a boom. The firm mentioned could not meet the demand in 1919; in the year 1920, the output was about three timea larger than at present. The number of employees varied as follows:—

Highest number employed in 1913 ...	845, working 55 hours per week.
Highest number employed in 1920 ...	1,260, working 47 hours per week.
Number employed at present ...	380 (60 per cent. working 47 hours per week and 40 per cent. working 34 hours per week).

The total number of persons employed in the manufacture of photographic apparatus was estimated by one witness at 20,000, but this number was stated to include some 12,000 to 13,000 making sensitised material.

25. A witness for the Applicants informed us that German competition is very severe in the larger forms of camera, especially those used by professional photographers, but the sales of this class of instrument are small; competition is felt most keenly in respect of the small plate camera. He stated, however, that the demand for the plate camera is diminishing, whilst the demand for the roll-film camera is steadily increasing. He added that the most formidable competitors of the British manufacturers imported their cameras from Canada.

26. The sole agent in Great Britain and Ireland of a German manufacturer stated that his firm sold 11 roll-film models for every

Barnet Matt-Emulsion Plates.

Self-Screen 300 H. & D.

Super-Speed 550 H. & D.

43, Dover Street,
Piccadilly, London, W.1.

To Messrs. Elliott & Sons, Ltd., Barnet.

Dear Sirs,

The batch of Barnet Super-Speed Matt Plates just received is extremely good. You seem to have conquered the control of the plate, and each batch seems better than the last.

I also appreciate the fine grain; it greatly facilitates the retouching.

Yours faithfully,
MARCUS ADAMS.

Send for particulars.

Manufactured only by
Elliott & Sons, Ltd., Barnet, Herts.

two plate models, and that of the plate cameras approximately half their turnover was in models which British manufacturers do not make. He submitted the following estimate for the whole camera trade of the proportion of supplies from various sources—

Camera sales in Great Britain :—

British make	13 per cent. of the value of the whole.
German make	7 per cent. of the value of the whole (as against 12 per cent pre-war).
Kodak	80 per cent. of the value of the whole.

This takes no account of supplies from other sources, which, however, are small.

27. We are able to supplement the evidence by the following statistics, relating to the imports of cameras from Germany, the United States and Canada, which have been abstracted by the Statistical Department of the Board of Trade from Returns furnished by the Customs. These figures, which do not include the lenses imported with the appliances, are as follows:—

IMPORTATIONS OF CAMERAS INTO THE UNITED KINGDOM.

	From Germany.			From U.S.A.			From Canada.

28. One of the witnesses attributed the prevalent unemployment in the British photographic industry to (*a*) over-production and over-stocking by dealers in 1920, (*b*) loss of export trade, (*c*) the general trade depression, and (*d*) the failure of British manufacturers to produce popular types of camera. We are unable to determine the relative importance of these various causes, but undoubtedly the camera industry must be regarded as, to a large extent, a luxury trade, dependent upon the general prosperity of the country.

29. The evidence on the subject of the comparative prices in the United Kingdom of similar British and German cameras was conflicting. The value of a camera is largely dependent on the type of lens with which it is fitted, and we found some difficulty in deciding whether articles submitted as similar were, in fact, strictly comparable. Broadly, the Applicants' case, which was mainly founded on the relatively cheap camera and was supported by a number of exhibits, was to the effect that German-made cameras were offered in this country to retailers at prices equal to from 47 to 66 per cent. of those of the equivalent British-made cameras, and that the retail prices varied from about 50 to 75 per cent. of those of the British goods, but there was little evidence of the actual sale of any considerable quantity. They contended, however, that, although the German and British cameras were capable of doing the same work, the German instruments were actually inferior, but that the degree of inferiority was not such as to compensate for the difference in price. Before the war, prices were arranged by agreement between the principal British and German manufacturers.

30. One witness for the Opposition, who contended that, generally speaking, German cameras are not cheaper in this country than similar British-made instruments, gave particulars as to prices which tended to show that especially in the higher-class type of camera the prices of the two makes are about the same. Another witness stated that the prices charged for the cameras of the German firm of which he is the sole agent in Great Britain were based on those of the Kodak cameras, and as these form so large a proportion of the total supply they must have a considerable influence on the prices of competing firms.

31. As we have pointed out, the number of cameras imported from Germany is only a small proportion of the total trade of the United Kingdom, and after reviewing the evidence, we have arrived at the conclusion that it is insufficient to show that they are being generally sold in the United Kingdom at a price lower than that at which they can be profitably manufactured in this country.

PHOTOGRAPHIC LENSES.

32. A very large proportion of photographic lenses being used in the manufacture of cameras, any falling-off in the sales of cameras is reflected in unemployment in the photographic lens industry. We have been supplied with certain incomplete statistics which show a decrease in the number of employees engaged by four different firms on the manufacture of lenses.

33. It was stated by one witness that Messrs. Zeiss fixed their prices at approximately 20 per cent. below those charged by his firm, this cut being, he suggested, what they considered was necessary to get the business. On the other hand, evidence was adduced by the Opposition which indicated that the list or retail prices of lenses of certain German manufacturers, although generally lower than those charged by his firm, were in very few instances lower than the prices of similar lenses of four other British firms. The witness in support of the Application contended, however, that German-made lenses are sold in this country below the prices at which they are listed by the German firms' accredited British agents, although he expressed the opinion that the agents themselves charged list prices for the lenses and that they were endeavouring to frustrate "back-door methods" of importation. We were informed by the Opponents that English camera manufacturers had agreed not to list German lenses.

34. After considering the evidence, we are of opinion that the Applicants have failed to justify the allegation that photographic lenses manufactured in Germany are sold in the United Kingdom at prices below those at which similar goods can be profitably manufactured in this country.

SUMMARY OF CONCLUSIONS.

51. Before summarising our conclusions, we think it right to draw attention to the fact that the value of the German mark in relation to the £ sterling has fallen from 1,400-1,470 on June 19* to 2,300-2,350 on July 27. It would not, however, be practicable to take this fact into account without reopening the whole inquiry. Our conclusions are as follows:—

(1) No evidence was submitted regarding the cost of production in Germany of any of the articles with which we are concerned, and we are, therefore, not in a position to express an opinion on the question whether they are being sold or offered for sale in the United Kingdom at prices below the

* The date on which the Committee concluded their public examination of witnesses.

cost of production as defined in Section 8 of the Safeguarding of Industries Act, 1921.

(2) The evidence placed before us in regard to microscopes, prism binoculars, cameras, photographic lenses and ophthalmic lenses is insufficient to convince us that such articles manufactured in Germany are being sold or offered for sale generally or on a commercial scale in the United Kingdom at prices below those at which similar goods can be profitably manufactured in this country.

(3) We are of the opinion that (*a*) metal spectacle frames and eyeglass mountings, and (*b*) mathematical drawing instruments, manufactured in Germany, are being sold or offered for sale in this country at prices which, by reason of depreciation in the value in relation to sterling of German currency, are below those at which similar goods can be profitably manufactured in the United Kingdom. We consider further, that, by reason thereof, employment in these industries is being or is likely to be seriously affected.

We are of opinion that the imposition of a duty on these articles would exert only a negligible influence on employment in any other industry using them as material, and also that the industries manufacturing these goods in this country are carried on with reasonable efficiency and economy.

(4) No evidence was offered to enable us to express any opinion on the question whether the conditions specified in Section 2, Sub-section (1) of the Safeguarding of Industries Act, 1921, are fulfilled in respect of any optical elements or optical or scientific instruments other than those we have specifically dealt with.

We wish to express our indebtedness to our Secretary, Mr. T. Turner, for the valuable assistance he has rendered us during the whole of our proceedings and in the preparation of this Report.

We have the honour to be,

Sir,

Assistants' Notes.

Notes by and for assistants will be considered for this column. Payment for accepted contributions is made on the first of the month following publication.

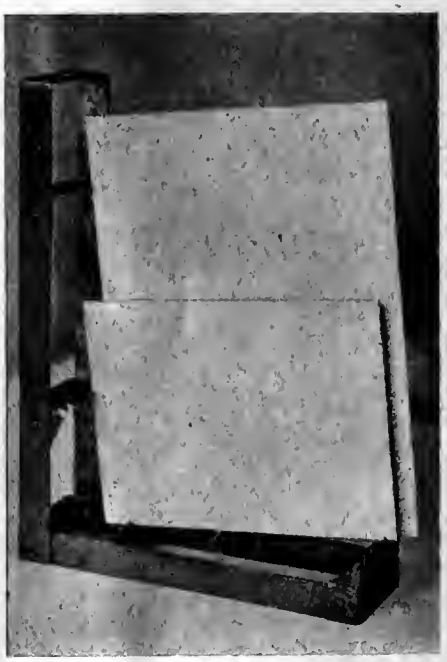
Cleaning Originals before Copying.

Many of the original prints received for copying would yield better results if they were cleaned before being pinned upon the easel. This must not be done indiscriminately, however, as what may freshen up one photograph may utterly ruin another. A Daguerrotype, for instance, will hardly stand brushing with the softest of camel-hair, while a collodion positive (often confused with the above-mentioned), if uncoloured, may be washed with water and a tuft of cotton-wool. These also may be revarnished to advantage, but a hot varnish must be employed, a cold celluloid varnish being quite unsuitable. Some cold varnishes are liable to dissolve the collodion, and with this the picture. Many of the "tin-types" brought in to be copied are coated with gelatine, and will stand a fresh fixing in hypo, followed by the usual washing and drying. A coat of varnish upon these will often remove the scratchy surface caused by rubbing. As regards prints, a collodion print must not be cleaned with spirit, but with plain water, which, however, may remove any spotting that has been done upon it. A platinum print may be rubbed over with very soft rubber or with bread if there is much dirt to remove, but the handling must be patient and gentle, and the print quite dry. Gelatine and albumen papers may be cleaned with water, with the risk of removing any hand-work, but methylated spirit, often advised, seems liable to make a dirty solution that soaks into cracks, especially into the edge of the print where it joins the mount.

Where hand work has been done upon prints of all kinds, a very safe thing to use for cleaning is good motor spirit or benzine. This will not affect any touches of water-colour, but will most certainly remove pencil-work. For any kind of print which bears pencil drawing it seems impossible to do anything more than brush off any loose dust.—C. M. K.

A Novel Plate Rack.

The plate-rack illustrated was made partly as an experiment to discover whether certain ideas would be practicable, and, secondly, in order to make use of a set of deep but narrow stoneware tanks that came into my possession. The result of the experiments proved perfectly satisfactory, and there is no reason why the principle of this rack should not be adopted with entire success. Wooden racks for tank use are not particularly easy to load, especially with panchromatics in the dark, and they displace a large volume of water, so that a roomy tank is needed, or care must be taken to use the right bulk of solution. Moreover, if a wooden rack is not filled up it tends to float and lift plates above the solutions at one end or corner. Metal racks, which have the grooves nearer together than wooden ones, are liable to corrosion and chemical action, which may affect the plates. The aim of the rack shown is first of all to hold the plate firmly at as few points as possible, so as to allow solutions in developing and fixing, water in washing, and air in drying, to circulate with a minimum of obstruction. It succeeds in doing this by supporting the back and edge of the plate at three points



only, a slight tilt preventing any tendency to slip out. The film side is not touched at all. This is achieved by having the teeth of the racks perpendicular on the right-hand side, and slanting away on the other side, so that by putting plates in with films to the left they drop into the notches until the glass comes up against a straight side.

That there is no particular difficulty in loading up I proved by taking the rack, as soon as I received the first model, into the dark-room with a packet of spoilt plates and loading up in absolute darkness. With no previous trial the operation was as quick and accurate as with any other kind I have used. Also the plate will not easily drop out, as I have repeatedly demonstrated by swinging a rackful about quite happily, and it may also be noted that the same rack will accommodate more than one size of plate.

By means of a small hole in the top bar the rack can be hung upon a hook screwed into the wall. Drying of negatives thus takes place evenly and rapidly, while they are out of harm's way and require no shelf-room.—D. Charles.

FORTHCOMING EXHIBITIONS.

December 9 to 31.—Rochdale Amateur Photographic Society. Particulars from the Hon. Secretary, W. Lord, 10, Derwent Street, Rochdale.

1923.

February 5 to March 3.—Northern Photographic Exhibition. City Art Gallery, Manchester. Latest date for entries, January 12. Particulars from the Hon. Exhibition Secretary, Walter Johnson, 30, Hartington Road, Chorlton-cum-Hardy, Manchester.

February 10 to 24.—Scottish Photographic Salon. Particulars from the Secretary, George A. Ross, Northfield Cottage, Brechin.

February 12 to 14.—City of London and Cripplegate Photographic Society. Latest date for entries, January 29. Particulars from the Hon. Secretary, J. J. Butler, 7, Gresham Street, London, E.C.2.

February 14 to 17.—Horsham and District Camera Club. Latest date for entry forms, February 3; exhibits, February 7. Particulars from the Hon. Secretary, S. Mitchell, 33, Bedford Road, Horsham, Sussex.

March 1 to 8.—Birmingham Photographic Society. Latest date for entries, February 15. Particulars from the Hon. Secretary, J. E. Breeze, 178, Broad Street, Birmingham.

March 2 to 31.—Pittsburgh Salon of Photography. Latest date, February 5. Secretary, Charles K. Archer, 1,412 Carnegie Building, Pittsburgh, Pa., U.S.A.

March 13 to 16.—Exeter and West of England Photographic Exhibition. Particulars from the Hon. Secretary, R. W. J. Norton, 4, Buddle Park, St. Thomas, Exeter.

March 17 to 26.—Welsh Salon of Photography. Latest date for entries, March 10. Particulars from the Hon. Secretary, H. G. Daniel, 154, Penylan Road, Cardiff.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications December 11 to 16 :-

CAMERA DEVICE.—No. 33,887. Devices for determining distance from lens to plate, etc., in cameras. K. G. Hagstrom and A. J. Ostlind.

REFLEX CAMERAS.—No. 34,026. Reflex cameras. R. G. Matthews.

PICTURE TRANSMISSION.—No. 34,181. Method of transmitting pictures to a distance. Picturadio Corporation.

CINEMATOGRAPHY.—No. 34,221. Production, projection and viewing of cinematograph, etc., pictures. W. J. Haydock.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

CAMERA FOR WHILE-YOU-WAIT POSTCARDS.—No. 182,117 (June 22, 1921). The specification describes certain improvements in the photographic apparatus, described in specification No. 166,524 ("B. J.," 1922, November 17, p. 699-670). The red observation glasses or a joint glass for the two observation apertures are lifted by the action of a spring and fixed in the removed position so that, on the door being closed, they are released and automatically returned to the closed position. The wall of the box, on which the carrier and the focussing screen are mounted, may be rotated together with the carrier frame and focussing screen, and the objective frame connected to the copying frame support by removable bellows.—Wilhelm Feuerzeug, 30, Briggittenauerlände Vienna XX., Austria.

The following complete specifications are open to public inspection before acceptance :—

TRIPOD HEADS.—Heads for camera tripods and like apparatus. J. Mery.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, JANUARY 1, 1923.

Bradford Photographic Society. Whist Drive and Dance.
Forest Hill and Sydenham P.S. 1921 R.P.S. Competition Prints on view.
Walsall Phot. Soc. "Paget Colour Slides." Paget Prize Plate Co.

TUESDAY, JANUARY 2.

Royal Photographic Society. "The Lamplough Flash Lamp." H. Lamplough. "Demonstration of German Aeroplane Camera." A. C. Banfield.
Bournemouth Camera Club. Competition. Prints made from negatives taken on Club Rambles.
Cambridge and District P.S. "'Ilford' Lantern Plates." A. Brooker.
Exeter Camera Club Exhibition of 1922. R.P.S. Affiliation Competition Slides.
Hackney P.S. "Modern Negative Making." Kodak Co.
Maidstone and District P.S. "Bromoil." H. W. Witcombe.
Manchester Amateur P.S. "Across France to the Pyrenees." W. Butcher & Sons, Ltd.
Morley Amateur P.S. Members' Evening. Social and Supper.
Portsmouth Camera Club. "The Exhibition Picture." Eng.-Cmdr. E. J. Mowlam.

WEDNESDAY, JANUARY 3.

Bristol Photographic Club. Musical Evening.
Croydon Camera Club. "Reminiscences of a Summer Holiday in the Swiss Alps." C. Keifer.
Leighton Buzzard and District C.C. "The Romantic in Landscape." R.P.S. Lecture.
South Suburban and Catford Phot. Socs. "Rambles in Palestine." F. R. Salmon.
The Photomicrographic Society. Members' Evening.
Wolverhampton Phot. Soc. "Landscape Photography." H. Rushton.

THURSDAY, JANUARY 4.

Edge Hill Camera Club. Social Evening.

Kodak Staff P.S. "Off the Beaten Track at the Zoo." J. E. Saunders.
Liverpool Amateur P. Assoc. Lecturettes by Members.
Richmond Camera Club. "Shutters and Shutter Testing." T. Smith.
Sunderland Phot. Assoc. "Transferotype." R. Chalmers.
The Camera Club (London). "The Evolution of the Lantern Slide." W. L. F. Wastell.

CROYDON CAMERA CLUB.

Mr. J. M. Sellors resumed and concluded his "Common-sense Exposure System, for bromide papers, lantern-slides, etc." Yielding to the persuasion of a member, who pointed out that in fairness the club should not alone be afflicted, the learned honorary secretary has graciously promised to prepare a description of the system and slide-rule, which doubtless will appear in the "B. J." in due course.

Practically the same system (since improved) was demonstrated by him over nine years ago, and he was then subjected to a very severe test. Three negatives not previously seen by him and three sheets of bromide paper of different brands were handed him by doubting members. Based on density-meter readings of the negative, and estimation of the speed of the papers under a step-wedge, three enlargements were made. They proved to be technically perfect, and the pronounced sniffers present had to abate their nasal intake.

Mr. Sellors said that he had found a range of speeds in present-day bromide papers in ratio 1 to 63, and different batches of the same brand often varied widely. If any sensible person wants to know the time he consults a watch or a clock, he continued. Why not, therefore, adopt almost as simple a procedure for finding the correct time for an enlargement.

An analogy might be drawn between the curves of plate densities and human tendencies. The period of inertia (=0) was represented by the teetotaller. A happy mean by the moderate drinker, full of beans and bounce, equivalent to a gamma of 1. Over-exposure and over-indulgence induced a flattening of tones and ideas respectively, whilst reversal was represented by the gentleman

in the gutter. At this juncture the "office boy," alleging a gamma of only 0.25, demanded and obtained the usual interval.

This brightened things up a bit. Mr. Wadham had come to the conclusion that if the density-meter were furnished with a powerful spring and easy release it would form a rat trap of real utility. The question of stained negatives then arose, and Mr. Jobling suggested standardising their densities by means of a Wynne actinometer in conjunction with the rat trap. Mr. Purkis said that readings should be made through blue glass, but on thinking the matter over, at the not unduly polite request of Mr. Salt, said no more on this point. He deplored that the average amateur, who often took infinite pains in other directions, took no steps to become familiar with the A B C of Messrs. Hurter and Driffield's investigations.

Mr. Ackroyd mentioned he had tried the system advocated for lantern-slides. Previously, on an average, he had only obtained two good slides out of a dozen plates, but since adopting it these numbers had been reversed. "To secure twelve good lantern-slides from two plates is indeed a feat," commented Mr. Salt. Mr. Ackroyd, somewhat short in manner, explained that ten good slides out of a dozen was meant.

Standard illuminants within the reach of the ordinary amateur were next considerd. It was agreed that an electric bulb run off the main was a ludicrous solution of the problem. In the same category were bats-wing burners, now the cash-consuming thermal-units are in force. Better, an incandescent gas burner or acetelyne jet. The two latter, Mr. Purkis pointed out, should always have a screen in front perforated with an aperture small in comparison with the area of the flame. Mr. Hibbert followed with a general eulogy of the lecture. Recognition, he thought, ought to be made for the enormous amount of labour it must have involved. Someone suggested "passing round the hat," but a hearty vote of thanks was accorded instead.

Commercial & Legal Intelligence.

Copyright Infringement by Authorizing.—In the King's Bench Division of the High Court, on December 19, before Mr. Justice Rowlatt, the action of the Performing Rights Society, Ltd., against the Ciryl Theatrical Syndicate, Ltd., and P. M. Faraday, was heard. As reported in the "Times," the plaintiffs in this action were the proprietors of the right of performing in public a large number of musical works, and the defendants carried on business as producers of plays at the Duke of York's Theatre, W.C. The claim was for damages and an injunction in respect of the infringement by the defendants of the plaintiffs' copyright in works known as "Mary" selection and "Colonel Bogey" march, which had been performed at the Duke of York's Theatre in July, 1921, without the consent of the plaintiffs.

In delivering judgment, Mr. Justice Rowlatt said:—In this case I want to say a few words about the Copyright Act, 1911. By section 1 (2) the rights included in the word "copyright" are enumerated, and one of these rights is to authorize the performance. That is to say that one of the rights protected is the mere authorizing as opposed to the authorizing followed by acting upon the authority. Secondly, authorizing does not mean giving power to an agent. Authority can be given to a person to act without such person being an agent. Thirdly, I do not think the word "authorize," has any relation at all to the character which the person giving the authority bears. If a person authorizes a thing to be done, it is not to be said he does not do it because he is acting as agent for somebody else. In making a contract, a person who acts as agent is not a contractor because his principal is the contractor. But in authorizing a thing to be done, a person does it himself, although he may be only acting as agent for someone else.

Section 2 (1) deals with infringements, and it makes a person an infringer who does any act which the proprietor of the copyright alone has the right to do. It makes an infringement the doing of anything which comes within the meaning of the word "authorize," which I have just explained. In this case the defendant syndicate were the lessees of the theatre and the defendant Faraday their managing director. Mr. Faraday engaged Mr. Bobbé when the theatre was taken over by the syndicate. In the course of performing, Mr. Bobbé—who selected the music—infringed the plaintiffs' copyright. Mr. Faraday could have prevented that. He had power to prevent Mr. Bobbé playing any particular piece and he had power to dismiss Mr. Bobbé. If Mr. Faraday, as managing director, allowed the performance, he authorized it. Mr. Faraday wrote that he did not care what was played, and if, in consequence of that, music was played which was an infringement of copyright, it rested upon him alone. There was ample evidence that Mr. Faraday authorized these infringements, and there must be judgment against him and also against the defendant syndicate. Plaintiffs are entitled to an injunction, and therefore there will be judgment for the plaintiffs with an injunction and costs, and they may take out, as damages, the £10 paid into Court.

News and Notes.

Panoram Kodaks.—A new booklet has just been issued by the Kodak Co., containing particulars and instructions for use of the Nos. 1 and 4 Panoram Kodak cameras, making pictures 7 by 2¼ in. and 12 by 3¼ in. respectively.

Held Over.—Owing to the fact that the present issue has been clased for press several days earlier than usual, by reason of the Christmas holidays, a number of notes, answers to question, etc., are unavoidably held over until the first issue in the New Year.

Welsh Salon of Photography.—The Wales and Monmouthshire Photographic Federation will hold the Welsh Salon of Photography at Cardiff from March 17 to 26. The last day for entries will be March 10. Entry forms and prospectus are obtainable from Mr. H. G. Daniel, 154, Penylan Road, Cardiff.

Reduction in Lens Prices.—Messrs. Aldis Brothers, of Sare Hole Road, Sparkhill, Birmingham, the makers of the well-known Aldis lenses, inform us that on and from January 1 they are making a substantial reduction in their list prices, approximately 25 per cent. A small temporary list, embodying the new prices, has been prepared and may be obtained upon application to Messrs. Aldis.

Nature Photographs as Christmas Cards. — Handsome cards, which made capital Christmas cards for nature lovers, were produced by the authorities at the Natural History Museum, South Kensington. They consisted of excellent photographs of the wonderful groups in the Bird Gallery, as well as of the mammals and even the insects. We are told that on some days a queue of people were buying them at 1½d. each.

Horsham Camera Club.—The first annual exhibition arranged by this club will be held in the Town Hall, Horsham, for one day, February 14 next, and at the club premises from February 15 to 17. There are five open classes, in addition to others for members only. Mr. C. P. Crowther, who will judge, will have silver and bronze medals at his disposal. Prospectus from the hon. secretary, Mr. S. Mitchell, 33, Bedford Road, Horsham, Sussex.

Photographs by Wireless.—It is stated that a photograph has been sent by wireless from Rome, Italy, to Bar Harbor, Me., and thence by mail to New York City, in less than 24 hours' time. The apparatus used was of the type originally developed by Dr. Arthur Korn, of Berlin, for telegraphic reproduction of pictures. He now has a laboratory in the Italian city, and has been co-operating with the U.S. Navy radio station at Otter Cliffs, near Bar Harbor.

London Camera Club.—We hear that it is the intention of the London Camera Club to resume the publication of a monthly journal of its proceedings, a policy which obtained for a while some years ago under the present organisation at John Street, Adelphi, London, W.C.2. The step will be welcomed, particularly if verbatim notes of lectures or communications of technical interest can be published in its pages. The files of the original series of the journal, issued when the Camera Club was in the Charing Cross Road, are a storehouse of many important papers by Abney, Hurter, and Driffield, and others.

Eaton School of Photo-Engraving.—The school conducted at Effingham, Ill., United States, by Mr. E. R. Eaton, a former instructor at the Bissell College of Photo-Engraving, has issued a prospectus of its courses of practical instruction in line and half-tone negative making for letterpress, photo-litho and offset printing. No mention is made in the prospectus of instruction in printing and etching. It seems difficult to understand that a course of training which does not include these parts of the process can

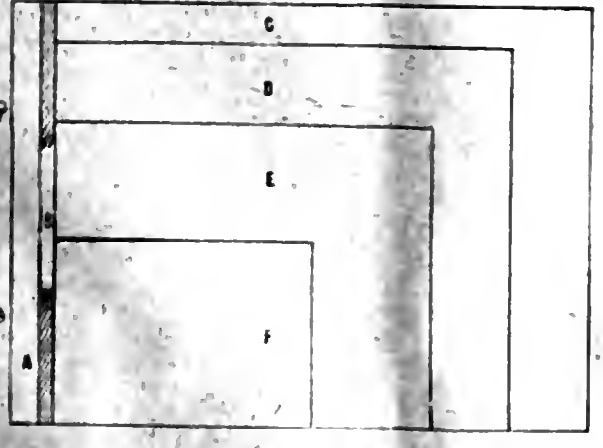
have any great value for students intending to make use of their skill commercially.

RETIREMENT OF MR. J. B. PAYNE.—A member of the photographic industry, who is among the oldest in point of long association with it, is retiring at the end of the present year in the person of Mr. John Buxton Payne, for many years managing director of the old-established firm of Mawson & Swan, Ltd., Newcastle-on-Tyne. In token of his long services to the company the shareholders of Messrs. Mawson & Swan, recently made a presentation to him of a silver rose bowl, appropriately of the local Tyne design. Everyone who has known Mr. Payne and has realised the activity of his long business life will wish him every leisure and enjoyment in his retirement. He will be succeeded by his son, Mr. Arthur Payne,

MR. JOHN BUXTON PAYNE.

who has been connected with the business on both the technical and commercial sides for many years, and who is well-known to the general body of photographers by his writings and experimental work, chiefly in orthochromatic photography. Under Mr. Arthur Payne's management and with the advantage of his father's advisory aid as chairman of the company, there can be no doubt that the business of Mawson & Swan will continue to be carried on upon the lines which have merited respect for so long a period of time.

STANDARD ALBUM SIZES FOR COMMERCIAL PHOTOGRAPHS.—The Commercial Photographers' Association of Chicago have adopted a standard size of mount for photographs, which are intended for binding into albums. The mounts are attached to a strip of card, of the same material as the mount itself, by a hinge of cloth. Holes are pierced through the strip with a 3/16th inch standard



punch, and the positions of such holes are altered to suit the different sizes of mounts. The holes should be punched in such a position that a distance of $\frac{1}{8}$th inch is allowed between the back edge of the strip and the centre of the hole.

We publish herewith an illustration of the standard chart supplied by the Association, together with the measurements, as they appear in the current issue of the "Bulletin of Photography."

A is the $\frac{3}{4}$-in. strip of card which is attached by the cloth hinge to B, $\frac{1}{4}$-in. wide, to the mounts. The holes for the plugs of the loose leaf binder are shown outside the strip, but these, of course, are punched through the strip as required. The centres of these holes are shown, and measurements are made from these. The largest mount, C, is $10\frac{3}{4}$ in. by $13\frac{3}{4}$ in., and the holes are punched 6 in. from centre to centre. Mount D measures $9\frac{3}{4}$ in. by $11\frac{3}{4}$ in., and the holes may still be 6 in. apart. In mount E, the measurements are $7\frac{3}{4}$ in. by $9\frac{3}{4}$ in., and the holes $4\frac{1}{2}$ in. from centre to centre, while the smallest mount, F, measures $4\frac{3}{4}$ in. by $6\frac{3}{4}$ in., and the holes are $3\frac{1}{2}$ in. apart.

MIDLAND COUNTIES FEDERATION.—Its year book for 1923 has been issued by the Midland Counties Photographic Federation. It contains lists of officers and federated societies, and a directory of the lecturers within the membership of the Federation who voluntarily offer their services. Their names and the titles of their subjects show the valuable help which the Federation can render through them to society secretaries in the preparation of attractive programmes. Further particulars of the Federation are obtainable from the Hon. Secretary, Mr. J. S. Lancaster, 9, Middleton Hall Road, King's Norton, Birmingham.

THE "KODAK MAGAZINE."—A copy of the first issue of the "Kodak Magazine," to which we recently referred, has reached our table. It is an attractive and well-illustrated 16-page periodical, with contents appropriate to the season. Mr. and Mrs. Cadby write of winter sports' photography. There is a paper on flashlight, including its use for making silhouette portraits. The fascination of night photography is underlined by a reproduction of a photograph of the Scott Memorial at dusk, illustrating an article on the pictorial wealth of Edinburgh. Mr. J. E. Saunders, noted for his photographs of animals in the Zoo, contributes the first of a series of chapters on "Photography with a Purpose." Practical notes, such as those on the use of a tripod and on fixing, have their place, and elements of art and humour theirs also. The little magazine will be certain to make friends for itself among the innumerable users of Kodak cameras. It is sold by Kodak dealers and at Kodak branches, price 2d.

Correspondence.

WHAT IS PICTORIALISM?

To the Editors.

Gentlemen,—I shall not "come on" to the slightest degree more than necessary. I have neither friend Evans's evident leisure, nor his mercurial energy. Suffice it to say that I never denied taste in selection of subject to Mr. Evans; and if he maintains that such taste constitutes creative art, as he calls it, I'm quite agreeable. It is, however, wrong to assume that the only alternative to over-exposure for shadows is "empty blackness." I assigned the difference between the works of White and those of Evans to printing and to negative-making facilities. Mr. Evans pushes these facilities as far as they will go, which is far beyond the limit of White; and of Velazquez. Farther still, Velazquez does *not* give detail in shadows. Mr. Evans had better have another look. It is amazing to me that he can couple his photographs (in this connection) with the works of Turner and Bosboom. It shows the hopelessness of argument, and explains his query, "What is Pictorialism?" No one can answer this in words; and, perhaps, only painters thoroughly know, because it is an intuitive perception, not a thing to understand by definition. "Waiting" and "studying every hour" will not give more than an almost inconsiderable factor in it. What Mr. Evans says about his tomb print supports my contention. One does not make a "picture" of carvings on a tomb.

I fancied I had done these Westminster prints full and generous justice. But Mr. Evans never was content with "all the toys"; he will have the "big doll" too.

Yours faithfully, F. C. TILNEY.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

E. T.—(1) Yes, but you will require a further diffusing medium in the shape of a sheet of flashed opal, placed near to the lamp. This may be obtained from Messrs. James Hetley & Co., 35, Soho Square, London, W.1. (2) The amount of enlargement is certainly great for an apparatus of this type, and we fear the exposure would be rather excessive with a lens of only *f*/8 aperture.

S. K.—We advise, first of all, copying the print as it stands. Then having obtained a passable negative, you may try and remedy the present print. Soak the print in water for about one hour and then place it in the following solution: Alum (saturated solution), 10 ozs.; hydrochloric acid, 3 drs. The print should be carefully watched in this solution and removed from time to time to a dish of clear water.

W. P.—Photograph the wording (from print, preferably) upon a thin celluloid Process film. This will give you clear letters on a black ground, which may be used for printing upon your cards. If you have arranged the words in the position they will occupy upon the postcards the wording negative may be used to print after the card has been exposed. If you require the wording to print with each negative, remove a portion of the film from the bottom of the picture negative and place the name strip in this position when printing.

M. S.—Coat the glass side of your negative with matt varnish in which has been dissolved a flake or two of iodine. When dry, scrape away the varnish covering the part of the machine you wish to show. The background in the whole negative should now be painted over with "Photopake," taking care that the outline does not cover any small detail of the machine. You will thus get a faint printing of the parts of the machine which are not essential to the illustration, while the essential part will show strongly against a white background.

V. R. T.—The film may be removed by soaking the negative in the following solution:—

Methylated spirit	1 oz.
Water	2 ozs.
Hydrofluoric acid	60 minims.

When the film appears to be leaving the glass at the edges it should be rolled up by aid of the finger, keeping the film all the while under the solution. When quite free from the glass the film should be washed for five minutes in running water and then placed upon its final support.

W. H. V.—We should suggest the Barkay reflector with a 3,000-c.p. lamp, and on the other side of the studio a 2,000-c.p. lamp, as you suggest. By this means you would have a good amount of light, but for the photography of children another lamp of about 3,000-c.p. would be necessary, to be used only as required. You would then be able to obtain well-exposed pictures and be sure of your results. It is rather difficult to advise you in reference to the lens, as price enters rather largely into the question, but for preference we should obtain either a Cooke Series II. portrait, or a Dallmeyer Series A or B portrait.

A. G.—A formula for a combined developer and fixer to produce black and white results is as follows:—

Water, to make	40 ozs. fluid.
Hydroquinone	½ oz.
Soda sulphite	4 ozs.
Soda carbonate	4 ozs.
Hypo	8 ozs.
Liq. ammonia .880	2 fl. ozs.

Addition of more ammonia to the developer gives more vigour. The plates develope (and partly fix) in two or three minutes. They can then be examined in daylight and fixed in plain hypo.

REFLECTOR.—Your studio should prove quite large enough for moderate groups, but you will require more light. The two 3,000-c.p. lamps on the right-hand side should be augmented by one other of 3,000 c.p. placed in the position marked, while on the other side you require two lamps of the same candle power. You could increase the light still further by using the Barkay reflector. A spot light should be extremely handy; indeed, we think the general utility of such a lamp demands its use in the studio where special lighting effects are attempted, as the light may be concentrated over areas extending from about 10 inches to many feet.

H. C.—The usual method for reducing the intensity of a background in a subject such as that of the machine which you send is to coat the back of the negative with a matt varnish and to scrape away this latter from the parts over the foreground portion of the subject. If still greater reduction of the background is required, a very little yellow dye may be added to the varnish. In fact, a usual way of colouring the varnish for this purpose is to dissolve in it a flake or two of iodine. You can get a suitable ground glass varnish from, say, the Vanguard Manufacturing Co., Maidenhead, and from this same firm you can also get a preparation known as "Billdup," which can be used in a somewhat different way. It gives a clear coat on the glass side of the negative, which then can be worked up with a stump and powder for reduction of the background. But for your special purpose the ground glass varnish method is the better.

O. S. R.—(1) The curtains should be loose enough to run freely on the wires. A sag of 3 inches in the middle is enough. (2) If the sitter is brought well forward away from the background the back lighting will give little trouble, screens or backgrounds may be arranged so as to intercept as much as possible. (3) We do not think the 4 curtains enough to cover 10 ft. of glass, five black ones would be better. There is really no need for so many white blinds, three would be ample. (4 and 5) About 10,000 c.p. distributed in such a way as you may choose, say four 2,000 c.p. and two 1,000 c.p. You would not need always to use the full number, but it makes the lighting simpler to have a reserve of power. The lamps may be arranged in a curve or L-shape, the front ones being about 8 ft. high and about 6 ft. from the background, the side ones and that at the angle of the L should be lower, say 6 ft. If possible all lamps should be made to raise and lower. (6) Choose a small sized panelling, each panel say 12 inches wide and 15 to 18 inches high. Medium dark shade, not "antique" colour. (7) The lens is excellent value for the money, and is quite suitable for portrait work; the field is not as flat as those of the more expensive types. (8) We know of nothing more satisfactory than the cylindrical oil heaters. If these are kept clean they are practically odourless. (9) There is no way of economising current while focussing except by switching off some of the lamps. For effective control of the lighting each lamp should have a separate switch.

MONTHLY SUPPLEMENT

ON

Colour Photography.

CONTENTS.

RAYDEX THREE-COLOUR PRINTING.

To anyone who has not himself experimented with three-colour photography the process described in detail appears intricate and full of difficulties, but in actual practice these intricacies and obstacles disappear, and, given reasonable care, once the original negatives are made the procedure is as simple as any other. No special apparatus is needed except that the camera must be adapted for plates, that the slides move easily in their guides, and above all that the apparatus is steady and firm, for the slightest movement during the taking of the three negatives is fatal to success. In addition to the camera, three-colour filters—red, green and blue—are required, and it is most advisable to procure a set of these from the start, as such a set is tested before leaving the factory to fulfil the following requirements:—

(1) Give the same sized image.

(2) Be of identical thickness. These filters are made of suitably dyed gelatine films, and may be used either unprotected or cemented between glass; if the bare films be employed they may be placed in front of the lens, taking care not to damage them by finger marks—to which the film is very susceptible. If they are cemented between glass the latter must be of the very finest quality and optically worked to enable them to be used in front of the lens; if used behind, thin plate glass will suffice. In the third alternative position—i.e., placed immediately in front of the plates, as in a repeating back—the quality of the glass is immaterial.

In outline the process is as follows:—

(1) Three negatives are made, each through one of the filters referred to.

(2) Three bromide prints from these are made.

(3) Three-colour positives are made from the bromides on yellow, red, and blue tissue, and subsequently by means of transparent supports superimposed in exact register on a final paper base.

We will take first the making of the negatives. It is best to experiment with still life subjects which can be taken indoors, thus doing away with any difficulties arising from movement due to wind—flowers, fruit or butterflies make admirable trial subjects, the more brightly and sharply defined the colours the better, as this makes the process the easier to follow. The trouble concerning wind in outdoor work to which I have referred is, of course, the waving of branches, trees, etc.; in an ordinary monochrome reproduction this is irritating, but it is even more so in three-colour work, as it will give rise to colour fringes.

A method of obviating this is to practice counting seconds and half seconds without reference to a watch—being thus enabled to keep an eye on the subject while the exposure is being made, as soon as a breeze springs up and movement seems imminent the shutter may be closed and reopened when all is still again. The moment of opening should be reckoned as 0, not 1, and if it is found necessary to close the shutter when, say, 3 has been counted the time of re-opening should be the same as that counted on closing.

We will suppose that it has been decided to make the first attempt on a butterfly. Having pinned the subject on the easel and sharply focussed, the next step is to ascertain the correct exposure by the aid of a meter. A very full exposure is necessary, two or even four times that indicated by the reading being not excessive. We will suppose that using *f*/8. the meter indicates ¼ sec., and we decide to give a normal exposure of 1 sec. The next step is to find out the multiplying factors for the filters in use. Presuming we are using Wratten tricolour filters and Wratten Panchromatic plates we shall find the necessary factors on the card accompanying the latter—we will say that these factors are:—Red 7, green 10, blue 6, then we shall have to give 7 secs., 10 secs., and 6 secs. respectively. (By the way, it is always advisable to number the plates 1, 2 and 3 when filling the slides, and always to work in the same order—red, green, blue or blue, green, red, to obviate any subsequent difficulty in identifying the negatives.) Backed plates should always be used. Inserting the red filter in the holder, the negative numbered 1 is exposed for 7 secs.; reversing or changing the slide, as the case may be, and altering the filter to green; No. 2 is exposed for 10 secs., and finally, No. 3 is exposed through the blue filter for 6 secs. Care must be taken in using the filters to see that they are always placed in position the same way; there are small labels on each Wratten filter, and by means of the lettering on these this is quite easy of accomplishment. Another point is that great care must be taken not to jar or move the camera in any way while removing old or inserting new slides.

Having given the plates identical relative exposures the next procedure is to give them identical development—in fact, from this stage, whether we are dealing with plates, bromide prints, or colour positives all must have exactly the same treatment to ensure uniformity of the final result. To this end, then, we develop the three plates side by side in a dish, or better still, in a tank, and thus escape the temptation to lift any one of them from the developer for inspection, which would be liable to impair the uniformity of development. Having fixed, washed and dried the negatives, we are ready for the next step, which is to make the bromide prints.

The paper employed for this purpose should be cut off from a roll, each piece in the same direction of the grain to secure equal expansion during the subsequent treatment. The Raydex Co. supply bromide paper in rolls for this purpose in two grades, fast and slow. We now cut off four from the roll, one for each of the negatives and a smaller piece for use as a trial exposure; providing the negatives have been correctly exposed the time required to obtain a good print from the green negative is the correct exposure for all three. Having marked each piece of paper R, G, and B, in pencil on the back to correspond with their respective negatives, we proceed with the printing; they should preferably be printed side by side simultaneously, but if the size of the negatives or the limitations of the source of light prohibit this they may be printed in succession, taking care that identical exposures be given and that the intensity of the light is stable. They are then soaked in cold water for a little while and developed together in the same dish with amidol or M.Q.—developing them right out as would be necessary for subsequent sulphide toning or the Carbro process.

Having thoroughly fixed and washed the prints, the next stage—the making of the colour positives—may be proceeded with, or the prints may be dried and operations continued at a later date; from now onwards all the operations may be performed in daylight.

For the third stage, the making of the colour positives, the following articles are necessary:—

Three transparent celluloid supports.

Three pieces of pigmented tissue or "colour sheets," yellow, red and blue, cut slightly larger than the bromide prints in use.

Two dishes, one preferably large and deep.

Sensitising solution. Waxing solution. Flat squeegee.

About half an hour before they are needed the three transparent supports are waxed by pouring a few drops of the waxing solution on a clean, soft rag and rubbing it lightly over the support. If there is an excess it should be polished off with a clean rag, taking care to leave no streaks; but it is essential that the whole surface be covered, else there will subsequently be difficulties in stripping the final paper support.

If the bromide prints have been dried they must be soaked in water until limp and then placed on clean glass supports, e.g., clean negative glasses.

Now fill the larger dish with clean, cold water and immerse the three-colour sheets until limp—they will soon uncurl, and should remain in the water for two or three minutes—longer in hot weather—after which they are hung up to drain. Now proceed to measure out the sensitising solution, which is done by taking 1 dram of Raydex No. 1 and No. 2 solutions and making up with water to 1 ounce. The preparation of this solution should be left till the last moment, as chemical action between them starts at once. It will be found that one ounce is sufficient to sensitise three ½ pl. sheets, but care must be taken to avoid air-bells. In dealing with the colour sheets as in the case of the negatives, each must have identical treatment, and the operations should be carried through in the order in which they have been commenced, say, red, green, blue.

Now take the yellow colour sheet and immerse it in the solution, dispelling any air-bells, when it may be followed by the red, and lastly the blue; the duration of this bath is two minutes, during which time the dish must be rocked and the sheets continually moved. At the end of this period remove the yellow colour sheet with the left hand, and with the right take up the bromide print from the blue negative with its glass support, immerse both under water, and quickly slide the colour sheet on top of the bromide, holding them firmly so that there is no slipping, as chemical action takes place at once, and any movement would give rise to a double image. Remove them instantly, taking care that the surplus solution falls into a sink or other receptacle and not into the water, as, even in a weak state, it will work havoc with the succeeding bromides; squeegee them firmly together, again avoiding any slipping or movement, and then treat the "green" bromide with the red colour sheet, and, lastly, the "red" bromide with the blue. Now remove them from their glass supports, yellow, red, and then blue, and place them between blotting paper under a flat weight for about twenty minutes, when the action will be complete. It is recommended to practise applying the colour sheets to the bromides with two pieces of paper until dexterity and confidence are attained, as there must be no fumbling at this stage; subsequently, everything is plain sailing. The sheets should be applied as quickly as possible, otherwise loss of detail in the high-lights is liable to ensue.

When the twenty minutes has expired, place one of the waxed transparent supports on a level surface—a piece of plate-glass is excellent—and taking the yellow colour sheet with its bromide, gently strip the two apart, placing the latter in a dish of clean water: immerse the colour sheet in another dish of clean water for a few seconds, then drain and place upon the support; squeegee in all directions, and then place a piece of dry blotting paper on the back of the colour sheet and squeegee thoroughly to remove all moisture, or subsequent frilling may occur. Repeat this performance with the red and the blue sheets. After a thorough washing, the bromide prints may be re-developed and used again.

"Development" can be proceeded with immediately. This consisting of placing the supports in water at a temperature of 115 deg. F. After a minute or so the backing may easily be removed, and, having served its purpose, is thrown away, when the supports will be seen to be covered with a thick coating of pigment. To remove the superfluity of this they are moved about face downwards under water, holding them vertically at times to allow the pigment to drain away, but do not always drain in the same direction. At the conclusion of this stage the celluloids may be very gently mopped with a camel hair brush to remove any loose particles of pigment; they are then placed in cold water for a few minutes and set aside to dry. I have usually found it advisable to develop the yellow positive by itself, as otherwise particles of the yellow pigment adhere to the red and blue.

We now have three colour positives on celluloid supports, and it only remains to combine them on a final paper support—I am for the present dealing only with single transfer. Take a piece of transfer paper, soak it in clean cold water for about half an hour, then immerse the yellow colour positive and bring them into contact underneath the water, place them on a flat surface, gently squeegee, and set aside to dry, when, by slightly bending the celluloid, the transfer paper will leave the support, carrying with it the yellow print. Now moisten a soft cloth with petrol and gently rub the surface to remove the wax, finishing off with a clean cloth. Repeat this operation two or three times to make sure that the wax is removed, otherwise it may be difficult to strip from the next support, and then soak in water for a few minutes with the red positive. Remove them in contact, and quickly move the print about until it is in exact register with the red colour positive; then squeegee carefully so as not to disturb the registration, and put aside to dry, when the paper will leave the support carrying the yellow and red prints combined. Remembering to clean the wax off carefully with petrol, the same operation is repeated with the blue colour positive, and, when dry, the picture is complete. It will then have a highly glazed surface, which may be removed if desired by cleaning with petrol, followed by a short soaking.

The single transfer process necessarily gives a picture which is reversed. In some cases this is quite immaterial, *e.g.*, in flower studies, etc.; but when reversal is undesirable, the double transfer process must be used. Personally, in all cases I much prefer it to the single.

In this case a piece of temporary paper support is soaked in water for ten minutes, and then applied to the colour positives in precisely the same manner as in the single transfer process, only it is obvious that now the order of assembling must be reversed, *i.e.*, blue first and yellow last. When the three colour positives have been registered on the temporary

paper support the latter is treated with petrol to remove the wax, and then soaked in water for two or three minutes together with a piece of final support a little larger than the size of the picture—the Raydex Company supply the latter, or any of the smoother Autotype papers are excellent. Remove them in contact, squeegee, and then place between blotting paper for about five minutes. At the end of that time place them in water at a temperature of 120 deg. F. with the final support uppermost. The latter should be kept dry. After two or three minutes, turn them over so that the temporary support is uppermost, and submerge them under water, when the temporary support may be carefully stripped off, leaving the picture on the final support. Having consideration for the fact that three negatives are required and the present cost of plates, it is satisfactory to know that whole-plate prints may easily be made from small negatives by making enlarged bromides in place of contact prints; the exposures, of course, must all be accurately timed and all identical.

The process may appear very lengthy, but in reality it is not so. I have frequently made a colour print in a morning. Moderate heat may be employed to dry the colour positives on their transparent supports and in their various stages, and this hastens the proceedings. Having made the negatives, the remainder of the process should be an ideal one for the winter evenings.

H. J. CAMPBELL.

A MODIFIED TWO-COLOUR PROCESS.

In Patent Specification No. 169,533, granted to Mr. J. F. Shepherd and Colour Photography, Ltd., a process is described in which a yellow image is added to the combination of blue, green and pink. It is pointed out that a method of colour photography of this class has been described in Patent No. 26,608, 1910 (of Pfenninger and Townsend; no patent granted on the application.—EDS., "B.J."), in which a compensating colour-positive is prepared to be used as a third or fourth part print in a complete colour print for strengthening certain of the colours in the other colour-positives utilised in the resultant coloured photograph.

The present invention relates essentially to a modification of a two-colour process. It is known that a two-colour process by itself will not, generally speaking, reproduce in correct natural colours the colours or tones of a subject possessing several different colours. The invention, while still not being intended to reproduce exact natural colours, does effect an improvement of the result generally obtained by a simple two-colour process and results in a more pleasing picture.

According to the invention, in a two-colour process of the class described, one of the two negative-records is a record mainly of the green constituents of the object and the other is a record mainly of the red constituents. The positive image produced from the green record negative is coloured magenta or minus green and the positive image from the red record negative is coloured blue-green or minus red, and the two positives so coloured are combined in register with a third positive record which is coloured yellow and is obtained by superimposing the two negative records and obtaining a positive print therefrom.

Preferably the two-colour record negatives are produced simultaneously on two superimposed sensitive surfaces whereof the front surface, that is the one receiving the incident light, may conveniently be an ordinary non-colour-sensitised surface. One such method of producing two-colour record negatives and positives therefrom is described in the Patent Specification No. 134,238 (of W. Friese Greene and Frank Garrett. "B.J.," 1919, December 12, p. 728.—EDS.).

In carrying the invention into effect in the preferred manner, two dry plates are placed film-to-film and exposed in the camera, the emulsion nearer the lens being sensitive to blue and green mainly, and the other being sensitive to red; for example, a panchromatic plate. The screening effect of the first emulsion (which may be an ordinary non-colour-sensitised emulsion), due to its yellow colour, enhanced, it may be, by dyeing the emulsion suitably or by interposing a coloured filter film between the two emulsions, will ensure that the image produced on the second or rear plate will be mainly a record of the red constituents of the object, while the first or front negative will be a record mainly of the green and blue constituents, or, if a yellow light filter is placed in the path of the rays from the object, mainly a record of the green constituents.

From the first or green record negative a positive image in a magenta or minus green colour is produced, preferably by projection, the colour being produced by any one of the many well-known methods, for instance, by toning.

Similarly, from the second or red-record negative is produced a blue-green or minus-red positive.

Finally, the two negatives are superimposed in register, forming in effect a single negative image which is a record mainly of the red and green constituents of the object, and a third colour positive is produced from this composite negative, this positive being printed, toned or otherwise coloured yellow.

The three-colour positives thus produced are then superimposed in register to form the final picture, and owing to the effect of the yellow positive, which plays to some extent the part of the blue-sensation print in three-colour photography, the colour rendering is a much closer approximation to the original colours than would have been possible if only two colour positives, prepared from the originally exposed negatives, had been used.

It is, of course, obvious that the process detailed above may be varied in many ways without departing from the invention.

The positive images may be produced by any of the well-known methods either as transparencies or opaque prints; for instance, they may be pigment "carbon" prints, toned silver prints, or mordanted dye images. In the production of a coloured picture on paper one of the images may be a toned or otherwise coloured bromide print, the other two being transferred in register thereon from a temporary support or backing.

A colour-photography process of the class described which consists in preparing two negative-records, one of which is a record mainly of the green constituents of the object and the other is a record mainly of the red constituents, preparing positives therefrom and colouring the image of the positive of the green record negative magenta or minus green and the image of the positive of the red record negative blue-green or minus red, preparing a third positive by printing from the two negative-records combined and superimposed in register, colouring the image of the third positive yellow and combining the three colour positives in register.

THE TRIST THREE-COLOUR CAMERA.

In the "Colour Photography" Supplement for December 2, 1921, p. 48, we reprinted a short description of the camera designed by Mr. A. Ronald Trist, in the shape of an article by Mr. W. Penrose Gimble in "Penrose's Annual." The patent specification of Mr. Trist (No. 164,476 of March 6, 1920) adds some further particulars to those already given.

The invention relates to cameras in which three plates are successively exposed through filters and in which no reflecting or deflecting means are introduced into the path of the light passing through the optical system.

Means are provided to enable the effective aperture of each filter to be independently varied so that the exposure value of all the filters can be made similar and the actual time of the successive exposures constant regardless of the specific relative exposure value of the filters.

An apertured disc having a filter in each aperture may be so pivoted relative to the axis of the optical system that upon rotation about its pivot each of the filters will in turn be correctly placed about the axis. Each aperture, in addition to a filter, has a diaphragm so that the effective aperture of each filter may be varied as desired within limits. By means of the diaphragms, it will be obvious that, the exposure value of each filter may be adjusted to a suitable standard, *e.g.*, the exposure value of the slowest filter. In association with the optical system a shutter of suitable type and a magazine for colour sensitive plates, or films, are arranged in suitable relation, means being provided which, upon operation, make the repeated exposures and suitably change the filters and sensitive media until the required number of exposures have been made.

In use three colour filters are usually employed blue, green and red, and the effective aperture of these filters adjusted to comply with the maker's directions as found upon packages of colour-sensitive plates or films, so that a definite and uniform exposure may be given through each filter. When these adjustments have been made all that remains is to expose one sensitive plate through, say the blue filter for the predetermined period of time, change the sensitive plate and expose the next sensitive plate through, say, the red filter for the same period of time and similarly expose the next plate through the green filter, all of

which operations can be automatically effected in proper sequence by mechanically associating the plate-changing, filter-changing and shutter-operating gear.

In fig. 1 *a* is a disc pivoted at *b* and having four circular apertures formed therein; one aperture *c* is left blank and enables ordinary photographs to be taken when desired, for which purpose an ordinary iris *o* is employed in association with the optical system in the usual way, the iris *a* being maintained at full aperture when exposures through the filters are being made. The next aperture is provided with a blue filter *d*, and iris *e*, an iris-operating handle and pointer *f* and a scale *g* for enabling the diameter of the effective aperture through the iris *e* to be easily ascertained. The next aperture is provided with a green filter *h*, an iris *i*, an iris-operating handle and pointer *j* and a scale *k* for enabling the effective diameter of the aperture through the iris *i* to be easily ascertained. The last aperture of the series is provided with a red filter *l* which is also provided with an iris *m* an iris-operating handle or pointer *n* and a scale *z*.

The disc *a* may be rotated by a spring and controlled by an escapement device of suitable form to enable a step-by-step movement to be made by the disc *a* for disposing the filters in front of the optical system in proper sequence. Starting from the position indicated in fig. 1 which shows the blue filter *d* in place, the first operation might expose a plate; the second operation might simultaneously change the plate and release the disc *a* so as to place the red filter *l* in position; the third operation might expose another plate; the fourth operation might simultaneously change the plate and release the disc *a* so as to place the green filter *h* in position; the fifth operation might expose another plate, and the sixth operation might change the plate and release the disc *a* so as to bring the clear aperture *c* in front of the optical system.

To enable the above series of operations to be repeated the disc *a* is rotated by hand backwards by means of the handle *p*.

Whatever may be the mechanism or the sequence of operations employed it is absolutely essential for good results that the exposures through the three filters should be made with the smallest possible time interval between them. To attain this result the actual exposure time period through each screen is made constant and the aperture for each exposure is suitably modified to enable this to be done.

The necessary modification is effected by varying the effective diameter of the iris *i* and the effective diameter of the iris *e* relative to the effective diameter of the iris *m*.

Assuming that a lens having 150 mm. focal lengths is employed, the manufacturers have marked the packet of plates 6, 9, 12, for the blue, green, and red exposures respectively, and it is decided to stop the lens down to *f*/8. The effective diameter of aperture

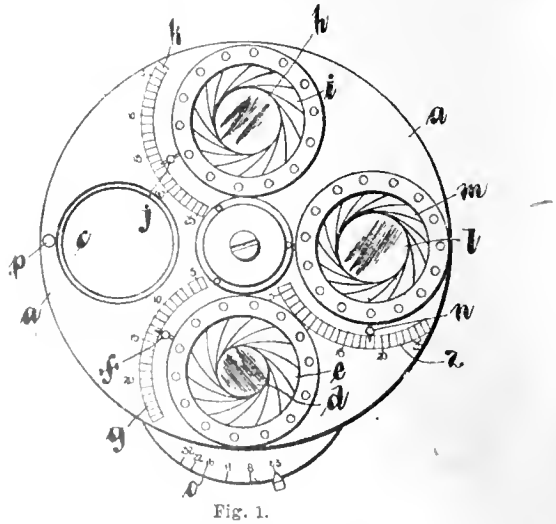

Fig. 1.

with such a lens at *f*/8 is approximately equal to 18.8 mm., and the iris *m* is adjusted to give this effective diameter to the aperture through the red filter *l* when exposure is effected. The manufacturer's indicator shows that the exposure through the green filter is to be three-quarters of that through the red filter, accordingly the area of the effective aperture of the green filter *h* is made three-quarters of the area of the effective aperture of the red filter *l* by moving the pointer *j* to a position on the scale *k* which indicates that the diameter of the aperture of the iris *i* is approximately 16.3 mm.

The iris *e* of the blue filter *d* is similarly adjusted and its pointer *f* is moved to a position on the scale *g* which indicates that the apertore of the iris *e* is approximately 13.3 mm., that is to say the ratio of the effective areas of the apertures throngh the blue and red filters is as 6 is to 12.

Referring to fig. 2 the tables *q*, *r*, and *s* enable the required diameters to be readily ascertained. The table *q* is for use when the highest value in the manufacturer's indicator is ten, the table

Fig. 2.

r is for use when the highest value in the manufacturer's indicator is eleven and the table *s* is for use when the highest value in the manufacturer's indicator is twelve and obviously more tables may be employed if desired.

The first column *t* of each table refers to apertures in focal units which are the effective apertures employed with the filter associated with the highest value the top row *u* of figures in each table refers to manufacturer's exposure indicators and the intersections of a horizontal line through the aperture in focal units employed with such filter and vertical lines through the particular indicators required will give the diameters of the apertures for the other two filters. The dotted lines in tables *s* refer to the actual settings referred to above.

THE GORSKY PROCESS OF COLOUR CINEMATOGRAPHY.—Particulars of a further stage in the development of the process of colour cinematography invented by Professor S. de Procoudine Gorsky are given in the December issue of our contemporary, "Conquest" (The Wireless Press, Henrietta Street, London, W.C.2, 1s.). These relate to the design of the camera, or rather of the optical device by which three separate images are obtained from a single viewpoint. Professor Gorsky divides his light before it enters the lenses, and uses for this purpose a system of three right-angled prisms. The longer sides of two of these are coated with bands of reflecting silver deposit. In the case of the prism which receives the light from the subject the bands occupy two-thirds of the space, each band being twice the width of the intervening bands. By this prism one-third of the light is transmitted and two-thirds reflected to the second prism, which in turn reflects one-third and transmits one-third. The three separate pencils of light, traversing different optical parallel paths, are taken up by three lenses, which form corresponding images on three separate bands of film, the gates of the films being placed in "staggered" fashion to the front surface of the prism block. Accessory non-refracting blocks form part of the system as means for equalising the absorption of light. It is claimed for this system, which we believe is a new device in making three-colour negatives, that it provides identical images. Our contemporary, "Conquest," reproduces a number of photographs of the cinematograph camera which has been built by Messrs. Cinechrome Instruments, Ltd., for carrying the system into effect. At the present time Professor Gorsky is at Nice engaged in making a series of films with the new instrument.

Colour Photography.

CONTENTS.

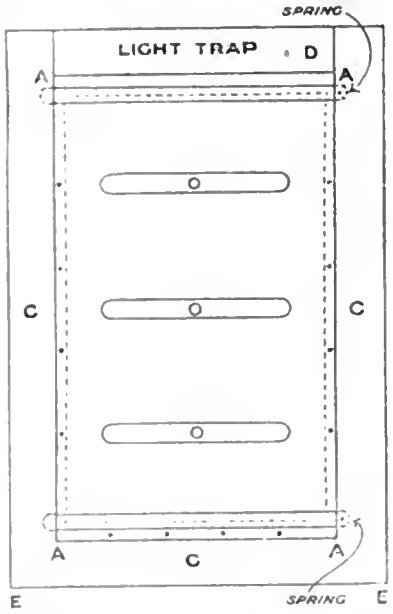
A PLATE-HOLDER FOR THE PAGET COLOUR PROCESS.

The lack of an efficient dark slide adapted to its needs has, to my mind, always been somewhat a drawback to the Paget process of colour photography. Some photographers that I have known have adopted this process with a view to making all their lantern slides with it, and, after a cursory glance at the maker's instruction, have loaded the best slides for the purpose that they happened to have, and when the resulting positives failed to register, blamed the seeming uncertainty of the process rather than the fact that their own procedure had made success very problematical. It cannot be too strongly impressed upon photographers adopting this beautiful process, that it is not sufficient to have the two plates in contact in the dark slide, but the latter must be so made or adapted that the contact is over the *whole* area, and not merely local, as sometimes happens, with the result that while one part of the transparency will register satisfactorily, others show only patches of false colours. The ordinary pattern of double dark-slide has been fairly satisfactory in my own work if strong springs are employed to supplement the central springs upon the metal dividing plate. When doing this there is always the danger that while sufficient contact is secured between the two plates the action of the springs is also forcing the slide apart, allowing the admission of light. These facts have led me to design the slide described below. Though primarily adapted for a 3¼ by 2½ pocket camera, the idea may be adopted for almost any make of instrument. I do not claim that there is anything original in the idea, but that it may be very satisfactorily employed for the purpose intended.

A general idea of the slide may be gathered from the drawing which shows the slide empty. It will be seen that three springs are fastened at the centre, which provide the requisite pressure from the back of the negative plate, while across the tops of the plates and at their extreme tops and bottoms are two extra springs holding them in position in the slide, and also ensuring contact. These are fastened at one side, pass across the two plates, and fasten in a recess notched out of the woodwork at the opposite side, A A, after the fashion of the older printing-frame springs. Four small pins are fitted two at each end, with two at the side, with the object of assisting in putting in the plates and also in keeping them square with each other. The position of the plates is shown in the sketch by rectangular dotted lines. It will thus be seen that the negative plate and its taking screen are squeezed together with a double pressure from both back and front, which ensures absolute contact.

The construction of such a slide is a fairly simple matter for anyone skilled in the use of simple woodworking tools, or one of the photographic cabinet makers would doubtless undertake the work at a reasonable cost. If the work is to be done at home the worker should set about it in the following manner. No dimensions can be given, since these vary with individual cases.

The base of the slide should be first cut out. This should be of fairly thick wood, according to the size of the slide, or from about 3-16 in. thickness for a small size up to ⅜ for a larger one. The three central springs should be first



fitted to this. They should not be too strong, and may range from about 3-16 in width for the small sizes to ¾ for the larger ones. Old clocksprings may be made to serve for this, and they should be bent into a half-moon shape and fastened to the slide with a screw through a hole drilled in the centre. The two other springs shown at A A in the sketch should then be fixed at one end at each side in the position shown. The sides c c c may then be attached with glue, and, after the latter has become well set, small screws may be inserted flush with the woodwork. These sections, c c, should be provided

with grooves or a projection, according to the design of the camera back at the edges. A plush light-trap should be fitted at the top, as shown at D. Care must be taken to see that the sections c c c are deep enough to allow the springs A A with the plates in position to be clear of the draw-out shutter. The grooves for the latter may now be fitted, and for lightness and saving in space I recommend that both the grooves and the draw-out shutter should be made of stout sheet zinc. A very simple way of fitting these is to first fix a strip of rather thicker zinc at the outer edges c c c, and over this a wider piece that completely covers these sections, taking care to get a good light-tight joint at the corners E E. Thus a channel is formed for the draw-out shutter to slide in. The latter may then be cut out after the usual pattern. The whole of the inside of the slide may be given a coat of dead black paint, which also gives a good finish to the metal work; the rest of the outside woodwork may be given a coat of varnish or finished in the same way at the discretion of the worker. If carefully made the above design allows little chance of light-leakage: if, however, this occurs, it may be due to faulty joints, which should be filled up with beeswax or putty.

To load the slide for Paget colour work, place the plate and its taking screen in the correct position within the pins on the central springs, and then bring the others A A across into the recess cut for each on the opposite side.

One point may be raised, *i.e.*, that of register. In the case of larger apparatus having deep slides, this may not be altered, but in the case of the smaller apparatus using thin metal plate-holders there will no longer be correct relation between the plate and focussing screen. In any case it is just as well to make a test of this by the very simple method described in the editorial article in the "B.J." Almanac for 1920, page 300, and I take the liberty of quoting it. "Insert a tapering strip of card between the focussing screen and a stiff flat ruler, such as a steel rule, laid across the frame of the screen. Secondly, make the same test on the plate holder with the plate in position and the rule laid across the face of the holder. The wedge of card should come to the same place in both cases, and a very slight error in register may be detected in this way."

I should suggest that if the error in register is found to be considerable that a new focussing scale be made and fitted or that the camera front be racked in, after focussing, the exact difference in register as indicated by the triangular wedge above mentioned. This should always be carried in the camera case.

R. M. Fanstone.

COLOUR CINEMA FILMS FROM LARGE AND SMALL NEGATIVES.

[The following is the description of a process patented by Zoechrome, Ltd., and Thomas Albert Mills for the production of "self-contained" cinema films in natural colours. It will be observed that the inventors propose to take a full size key film, which may be black or in a given colour, and to combine the positives therefrom with colour positives from smaller negatives by enlargement of the latter according to a process protection for which is granted in Patent No. 172,714.]

This invention relates to an improved method of producing cinematograph films in which each individual picture is a complete colour rendering of the subject.

There are produced upon the negative film (by the aid of suitable colour screens) a set of images of full or normal size (key images) and interposed sets of small sized colour-giving images, each preferably of half the linear dimensions of a key image. The small colour-giving images may be three in number, corresponding to the usual triple division of colours, and the key image taken without a colour screen so as to give the black and white effect only. Or the key image may also be a colour image, giving, say, the blue in the resulting positive film, either the blue being printed alone, from the negative key image, or by a double printing both the blue and a similar black and white or true key image, and only two small images may be produced. Each key image and its associated small images are taken simultaneously through separate lenses, and, as the lens for the large image has to have a correspondingly greater focal length, and if employed to give a direct image would form an obstruction for the small images, the increased focal length is preferably provided for by a prism or other reflector, allowing all the lenses to lie in the same plane. This displaces the key image from its corresponding colour images, and therefore the key and colour images of one exposure are interposed between the key and colour images of other exposures.

In producing the positive film from the original negative, the latter is moved at each operation through a distance equal to a key image and the following small colour images, closing up the key images on the positive film so that they are reproduced in succession without the interposition of the colour images, these being afterwards enlarged and superposed. The reproduced image, if the key image is to be in one of the colours employed, say blue, is suitably coloured or dyed, but if the key image is black and white the usual process only is employed. Or the same large image may be reproduced twice, once as a black and white image and once in colour. The reproduced key film is then coated with a sensitive emulsion, and one of the colour sets of images is then enlarged to the key size and superposed upon the key images, the new positive images being coloured to the required colour, complementary to that of the colour screen employed for the negative. The next set of colour-giving pictures is similarly superposed, and, in the case of the process employing black and white key images and three colours, the third set of colour images is then superposed, with the result that the finished film is a complete colour rendering of the subject, and can be projected by the usual apparatus upon the screen. The apparatus employed for producing the positive may be of the type described in Middleton's Patent, No. 16,353 of 1913 ("B.J.," September 18, 1914, p. 715). It is to be understood that the term "key image" is used in a wide sense, as the image which is originally taken of full size and thus serves as the most important image in giving definition to the picture, but it is not necessarily an opaque or black and white image in the positive picture.

In the drawings, fig. 1 is a diagram illustrating the production of a negative having a set of key images and three sets of colour-giving images; and fig. 2 is a similar diagram illustrating the case in which the key image is also one of the colour-giving images.

In fig. 1, A is the negative film. B, B are the key images of full size. C, C, C, are three sets of half-size colour-giving images arranged with one central image and two images side by side. D, D^1 are the camera lenses, of which the larger lens D is of twice the focal length of the smaller lenses D^1. E is a prism reflector. The lenses are arranged as shown at the right of the figure, the small lenses forming a triangle below the large lens. The triangle may be inverted to bring a pair of small lenses close to the large lens and leaving only one small lens at an appreciable distance. The reflecting prism E is arranged so that the pencil of light from the large

lens D, indicated by dotted lines, is reflected from the lower and upper surfaces *e*, *e'* and on to the film A, a distance of two full images existing between the resulting image and the images due to the lenses D¹. The length of the path from the large lens to the film is twice that of the direct path from one of the small lenses to the film so that the increased focal length of the large lens is provided for while allowing the lenses to be placed in the same plane. The shutter mechanism and the colour screen are not shown as they may be of ordinary type.

In fig. 2 the key pictures B¹ are produced by the aid of a colour screen, say red, and instead of separating the images

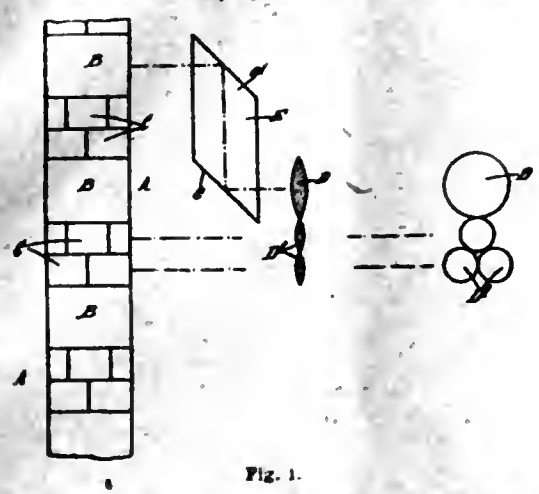


Fig. 1.

by a full picture width as in fig. 1 the separation is of half a picture width only, to accommodate a pair of small colour images C¹ taken through the two other colour screens of the set of three. The small lenses D² are placed symmetrically below the large lens D. Otherwise the arrangement is as in fig. 1, and the prism reflector E doubles the distance of the path from the lens D to the film.

In producing a positive from the negative film as shown in either fig. 1 or fig. 2 the key image is thrown upon the positive film and the negative film is moved for each exposure in the apparatus through the space of two pictures or a picture and a half according to whether the arrangement of

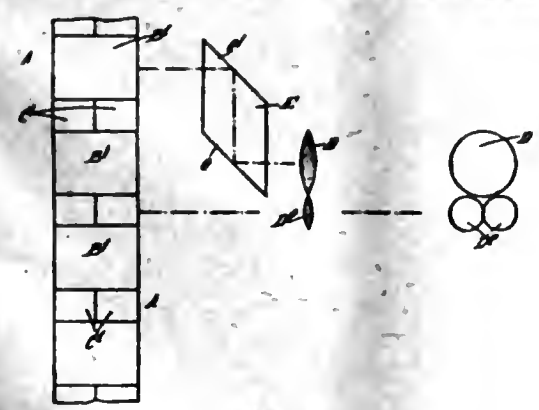

Fig. 2.

fig. 1 or fig. 2 is employed, the positive film being moved one picture space at a time. The positive film with the key images on it is then developed and fixed and may be varnished before sensitising again. If the key image is also a colour one the positive image is coloured to, say, blue. Or a black and white key image may be used and a second printing from the large images taken and coloured.

The resensitised positive film is again exposed and the enlarged images of one of the sets of small colour images superposed upon the key images. The lens system employed for copying is arranged to give the required enlargement, while for the key pictures, the original and reproduced images are of substantially equal size. The images B and C having been relatively displaced by the action of the reflector, the colour images superposed must be those separated by the intermediate images, as indicated by the dotted lines in the drawings, so that the colour images shall be those taken by the same exposures as the key images on which they are superposed. The positive film is coloured and resensitised again for the second colour set, the operations being repeated where a key picture and three small pictures are employed as in fig. 1. The final result is a positive film fully coloured and adapted to be projected by the usual projecting apparatus. The three-colour system has been taken as the basis of the method described and illustrated, but it is obvious that other colour systems may be used.

Owing to the fact that the key images and the colour images are taken simultaneously the original film should be moved more rapidly than is the case with an ordinary film, since the space of two or of one and a half ordinary pictures has to be covered between each exposure, while the coloured positive is moved at the normal speed for projection. Since the key image is of full size the projection on the screen gives a clearness of impression substantially as good as that of the ordinary uncoloured picture. To obtain this clearness it is not essential that the colour producing images should be so sharp, so that the smaller scale on which they are taken does not materially affect the sharpness of the result and the great advantage is obtained that the colour effect is given by an addition to the length of the negative film of only 50 or 100 per cent. according to the colour system employed. The disturbing rainbow effect produced when colour images are taken successively is also entirely eliminated by the simultaneous exposure of a complete set of images.

A NEW METHOD OF MAKING COLOUR PRINTS.

(A Note in "Penrose's Annual," 1922.)

In Volume 20 for 1915 of "Penrose's Annual" we described an interesting method of producing photographic prints in colour invented by Mr. John Lewisohn, of New York, and patented by him in America in 1913. Since that he has invented and patented in America and in England another process which is an extension and improvement on the former one, though utilising fundamentally the same means.

The method consists in first obtaining three negatives through the usual colour filters. A blue print on ferro-prussiate paper (the same as is used for engineers' blue prints) is made from the yellow printing negative. The entire blue part of this print is washed with a yellow dye, such as aurantia. It is then dried and afterwards immersed in a weak solution of silver nitrate sufficiently strong to dissolve the blue and leave the yellow image. The side of the print bearing the image is then coated with a blue-print sensitising medium, which may be applied before the print is dry after the preceding operation.

The re-sensitised print is impressed with an image through the red printing negative, which is adjusted to get the print in register. The blue print so formed is washed with a red dye, such as eosine red, then dried and treated as before with nitrate of silver to remove the blue, leaving the red image on the yellow image previously formed.

The operation of re-sensitising with the blue-print solution is repeated, and a print made through the blue printing negative, taking care to secure register. The print so formed will have the blue colour, so that it is unnecessary to remove this. The result will be a combination print of yellow, red and blue colours superimposed and will substantially reproduce natural colours.

It is self-evident the process can be used for only two or with more than three colours. The principle of the process consists in forming a series of superposing blue images, of which the preceding blue image has been substituted by another colour before the succeeding blue image has been formed. Presumably the washes of colour are applied locally with a brush, otherwise it would seem that the sheet of paper would be completely dyed. On this point the patent specification is not clear. We shall be interested to see further results of this process, which appears to be a very simple method of making colour prints.

WILLIAM GAMBLE.

THE TRIADOCHROME PROCESS OF MAKING THREE-COLOUR PRINTS.

Some months ago, namely, in this Supplement of May 6, 1921, page 20, we had a short note from particulars contained in a local newspaper of the process of three-colour printing worked out by Mr. J. F. Shepherd, of 10, Derwentwater Road, Acton, London, W., by whom the name "Triadochrome" has been given to it. Since then we have had the opportunity on one or two occasions of seeing the process in working and of examining a considerable number of the results, and have no doubt that many of our readers will be interested in hearing more of a method which without question has considerable commercial possibilities and has already found commercial applications.

The process is purely one of three-colour photographic printing from the customary set of three-colour sensation negatives. Mr. Shepherd's work has been directed towards perfecting a method of printing which can be put in operation on a commercial quantity scale with assurance of producing prints of satisfactory colour rendering and also uniform throughout a batch. In doing this he has reduced the operations required for the assemblage of the three-colour impressions to what appears to be an irreducible minimum, and thereby has rendered it possible to produce prints in any reasonable number on the day following the completion of the negatives.

Without going into minor details of manipulation, the process is as follows:—The red print (from the green-sensation negative) is made by the carbon process on a celluloid support. The blue print (from the red-sensation negative) is prepared on a transfer bromide paper, its blue colour being obtained by the ordinary process of iron toning and fixed in a special fixing bath to clear the whites and give a correct blue-green. The blue paper print is squeegeed down in register with the red impression on the celluloid, surplus water is blotted off, and, after remaining for about an hour, the paper support of the blue print can be stripped off, leaving the red and blue impressions together on the celluloid. It remains to add the yellow print (from the blue-sensation negative). This print is made on ordinary bromide paper and toned to a yellow by a special combined toning and bleaching bath process. It is in turn squeegeed on to the composite red-blue print on the celluloid and the whole assemblage allowed to dry. The original celluloid support can then be stripped off dry, leaving the three-colour print on the paper base provided by the bromide paper on which the yellow print was made. We were able to see from prints in various stages of making and from a number of completed results that the process yields quite satisfactory registration of the three images. As regards systematising the production of prints on a considerable scale, Mr. Shepherd provides a small test chart of red, yellow and blue colours, and a white, when photographing the original. This chart is recorded on the edge of each negative taken, and thus, in the making of the component prints, the work can be distributed between three separate departments, in each of which the printer has a standard before him to which he must work as regards depth of print and, in the case of the toned bromides, as regards producing the correct tone. While it is not claimed that the making of these prints is work for the slipshod hit-or-miss printer, experience has shown that printers of reasonable competence can make individually large numbers of red, yellow and blue prints which, when subsequently assembled, yield satisfactory three-colour results.

So far the negatives with which the process has been used have been made by successive exposures in an ordinary camera, and so have been of still-life subjects, such as pottery, paintings, textiles and other articles of manufacture. We have seen some remarkably good three-colour prints of hats and costumes, and Mr. Shepherd has even obtained some striking prints of the show windows of a large department store, photographed at night through the plate glass and by the artificial electric illumination.

Speed of production and uniformity in the results are the two outstanding claims which are made for the process—claims which, so far as our observation has gone, may be thoroughly substantiated. There is undoubtedly a great commercial demand for satisfactory colour photographs, particularly of manufactured goods in textile, pottery, furniture, and other industries, as well as among firms concerned in such businesses as flower growing, interior decoration, etc. The "Triadochrome" process certainly appears to have been brought to a stage at which it is capable of fulfilling such demands.

News and Notes.

BYE-PATHS OF COLOUR PHOTOGRAPHY.—Messrs. A. W. Penrose & Co. have a volume in the press on this subject. It is stated to be the work of a practical photographer who has devoted many years to the study of colour photography, and who prefers to conceal his identity under the pseudonym of "O. Reg." The volume is announced to deal with colour cameras, filters, colour-sensitising of emulsions, and the making of colour transparencies and prints.

THE GLORIOUS ADVENTURE.—The public exhibition of the film, "The Glorious Adventure," in natural colours by the Prizma process was begun a week or so ago at Covent Garden Opera House, London, W.C. More than ordinary interest attaches to it, since it is the first production of a drama or story cinema film in colours by a photographic process. When we referred (in this Supplement, May 6, 1921, p. 18) to last year's exhibition of Prizma colour films we had to point out that, while the results were most certainly a triumph of printing, the negatives were evidently made by the ordinary method of exposure, so that there was lack of identity between the images of each trio representing the three colour-sensations. Hence, in cases of rapid movement of the subject, there was the production of colour fringing around the outlines of objects in movement. As has already been announced, this disability has been removed by the design of a camera which yields identical images in each trio of exposures. The pictures now included in "The Glorious Adventure," which is a full-blooded drama with any amount of movement, emphatically show that this defect has been removed almost completely. At one or two places there was a momentary splash of what may be called stray colour, but possibly this was due to other causes, for example, accidental mechanical damage of the film. It is not too much to say that, so far as colour fringing is concerned, this difficulty has been overcome by the experts of the Prizma process.

When we come to the technical quality of the film, considered as a piece of animated photography in colours, it is necessary, in expressing an opinion, to distinguish between two kinds of scene. The action takes place very largely at close quarters, and almost without exception the photographic quality and the colour quality are both of them altogether excellent. In many instances the renderings on the screen of these phases of the story are supremely beautiful, and exhibit the most delicate colour tonalities of complexions and dresses, which are a veritable modern miracle when one has in one's mind the tiny postage stamp transparencies which are projected. We imagine that it is phases of this kind which have prompted some of the most appreciative eulogistic notices in the newspapers, a typical specimen of which is that the film is "a thousand oil paintings come to life." But as regards the more open scenes, whether outdoor or in the studio, it must be said that the photographic and colour qualities are of a much lower standard than that of the "close ups." We are afraid we can only say that this is so without being able to assign the cause. In some of the general studio scenes lack of sufficient illumination appeared to be indicated; some of the film had the appearance of being under-exposed. But the general outdoor scenes, for which, presumably, there was plenty of light, frequently were seen to suffer from an unnatural colour rendering in those parts which were relatively distant from the camera. We believe this is a difficulty in colour cinematography which is generally experienced, and which is perhaps associated in some way with the action of ultra-violet light. Then, again, the task of stage-managing large scenes containing a whole miscellany of colours must have been an enormously difficult one for the producer. When it is remembered how immensely superior the tonal qualities of modern cinema films are in comparison with those of, say, ten years ago, it is too much to expect that the first production under the entirely different conditions imposed by a colour record should be free from discordant notes. Probably all these three causes in various proportions are responsible for the less satisfactory renderings of the general scenes in comparison with those of the "close-ups," where the conditions of distance, lighting and composition are much more favourable. But we do not wish to emphasise these considerations. So much of the film is so admirable that, as a whole, it must be saluted as wonderful, and a very great triumph, even if not an entirely complete one, over great technical difficulties by the producers, Messrs. J. Stuart Blackton Photo-Plays, Ltd.

FACTS AND FALLACIES IN COLOUR PHOTOGRAPHY

The literature of colour photography is so scanty that any new book appearing on this subject is sure of a cordial welcome, especially when it contains the results of many experiments and much new matter. The author, who partially conceals his identity under the thin disguise of "O. Reg," gives special attention to the problem of the one-exposure camera, and wholeheartedly advocates the single reflector type (Bennetto's principle with compensators). So far, so good, and it is, therefore, all the more to be regretted that he should permit incorrect deductions to mar the value of his book and to treat the labours of others in the same field in a depreciatory manner. As most one-exposure cameras produce the three images by means of transparent reflectors, much space is given to considering the "refraction error," i.e., the error caused in the direct image by the cone of rays from the lens passing through the inclined reflector, and the means of compensation for this. Before dealing with this question, distinct exception must be taken to the statements on pages 9 and 16, that "Cameras on the two-reflector principle, like the chromoscope, cannot give three identical images." The answer to this is that "They do and have done so for many years past," a fact that the author could have easily verified by application to Mr. Butler. I have examined a good many Butler negatives, from whole plate to 4½ × 6 cm., and can assure prospective users of two-reflector cameras that the registration difficulty is a pure myth. A few days ago I took, with my Butler quarter-plate camera, a man-of-war dressed with flags, and the delicate tracery of the rigging provided an excellent test of registration from which the camera emerged with flying colours. It is, in fact, an old controversy, "Do Butler negatives register?" and I should not have raised the point, had it not been for these misstatements, backed up by the diagram of a badly designed chromoscope on page 9, and for the astonishing statement on page 28 that "One-exposure cameras with more mirrors than one, are only theoretical illusions and scientific experiments *ad absurdum*."

Fig. 1.—Camera made according to Patent 12,181 of 1909. Position and shape of prisms are shown by pieces of paper attached to camera. Filter holders and dark-slide resting against back of camera.

Let us, however, consider the refraction error problem more closely. The refracted image differs from the geometrically correct image by having one half contracted and the other half expanded. If the reflectors are parallel, this error is magnified, if they are at right angles, as in White's camera, this error is very nearly eliminated. I have recently designed a camera on the latter principle, and find that the direct refracted image is distorted to the extent that a wedge of glass from 0001 in. to 006 in. would cause, when placed in front of the plate.

The camera in question is designed for a 6¾ in. *f*/4.5 lens to cover a plate 3 in. × 4¼ in. The second reflected image is more difficult to correct, but this can be done by inclining the focussing plane, in spite of our author's denial of this possibility. To return to the Butler camera; how is his registration obtained? It seems quite plain to me that in the course of his

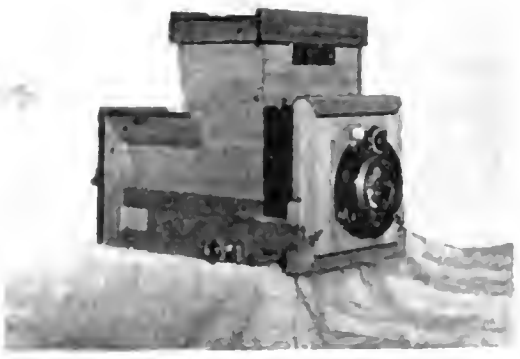

Fig. 2. Butler tri-colour quarter-plate camera.

adjustment, the first reflector is thrown slightly out of the exact angle of 45 deg., which is equivalent to inclining the focussing plane, thereby inducing a slight distortion of the picture, equal to that produced by refraction. In the same way the second reflector is out of the 15 deg. standard by a smaller amount. If the course of the marginal rays be traced it will be seen that astigmatism is introduced into the lens system, whose effect is to increase the depth of focus at the expense of definition, though as far as my experience goes with an $f/6.8$ lens the definition is entirely satisfactory. I have perhaps had to deal rather fully with this point, but the statements made are likely to prejudice people against a type of camera, which I believe to be by far the best for colour photography, and a type, which I hope I may be instrumental in putting on the market for the benefit of colour photographers. At the present time any further reference to this is premature. The principal trouble with a reflector camera is to get the mirrors absolutely plane.

Hamburger and Costen's patent for distorted reflectors is somewhat drastically dealt with on page 34, but I will leave these gentlemen to fight for themselves, merely contenting myself with the observation that I have seen the Polychromide camera, and the finished prints showed excellent registration.

In Chapter IV., which deals with "Real Inventions" in a somewhat sarcastic vein, I find a diagram depicting Ives' camera, patent No. 12,181, of 1900, though the author has "no desire to commemorate these imaginative geniuses." Unfortunately his criticism fails because he is unacquainted with the precise dimensions of the cameras concerned and the degree of stereoscopic error involved. Returning to the realm of fact, we find that Mr. E. Sanger-Shepherd designed and manufactured such cameras, prior to the war, and sold them as landscape cameras. A camera in my possession has an $8\frac{1}{2}$-in. lens, and the stereoscopic separation between top and bottom images is $\frac{3}{8}$ in. Registration is therefore perfect at distances over 10 ft., and I am informed by the designer that prints 20 in. × 16 in. have been made from his lantern-size camera. Two photographs are given of these unfortunate cameras, and I have indicated the position of the rhomboidal prisms on the S.-S. camera.

Space does not permit me to deal with the author's camera. I will only remark that to adjust his exposure ratio by using three plates of different speed is unsound. A far more philosophic method is to use equi-speed plates and a compensating filter on the lens.

His chapter on printing is frankly archaic. I believe that Rotary tricolour films have been off the market at least nine years. Raydex is the modern and easiest method of pigment printing, but there are many others that he might have tried, such as the beautiful dye imbibition process of Sanger-Shepherd and Bartlett, and the D.I.P. process is also most promising.

Notwithstanding these errors there is much of interest in the book, and it is recommended to the favourable notice of colour photographers if they will take the customary pinch of salt.

H. E. RENDALL.

ADDITIVE TWO-COLOUR CINEMATOGRAPH PROJECTION.

[A system of colour cinematography, which is the joint invention of an Italian and a French technician, Cesar Parolini and Gustave Perron, is described in a recent patent specification, No. 145,478. The inventors adopt a method of optical printing of side-by-side half-size positives from the negative taken alternately through orange and green filters. The pairs of positive pictures are combined by a pair of objectives mounted for production of a single composite image on the screen.]

THE invention consists in a process for the manufacture of a cinematographic film for projecting images in colours which comprises the taking of negative images by a cinematographic camera laid on its side so as to give images with their horizontal lines parallel to the length of the film, the speed being twice the ordinary speed of, say, fifteen images per second in order to obtain two images through two coloured screens in the time usually occupied in taking a single ordinary image or three times the ordinary speed in order to obtain two images and a blank, the increase in speed being obtained by the inclusion of a speed-multiplying gearing in the camera; then producing a positive from the negative by projection, the two films being arranged and moved relatively at 90 deg., the printing being effected in such a manner that the two images on the negative are together projected to produce on the positive film two side-by-side reduced images with their horizontal lines transverse of the film, and which occupy the surface corresponding to an ordinary image.

The projection of such a film is effected on an ordinary screen by means of an ordinary cinematographic projector, which is suitably modified instantaneously and momentarily for the purpose.

In the taking of negatives the film, which is an ordinary one, is exposed with the horizontal lines of the images taken parallel with the direction of the length of the film, that is, the taking of a photographs is effected with the cinematograph apparatus laid on its side.

The speed of exposure is about twice the ordinary speed of, say, fifteen images per second, in order that two images shall be obtained during the time usually occupied in taking one ordinary image.

When taking photographs of objects moving at a very high speed, the speed of exposure may be increased to three times or even four times the normal speed of exposure.

The camera differs from an ordinary camera in that, in order to obtain an increase of speed in the taking of photographic negatives, the driving mechanism of the apparatus is modified by the arrangement of a speed-multiplying gearing.

Moreover, and without modifying the shutter, a transparent disc coloured half green and half orange will be arranged in front of the objective, on a rotating axis actuated by the multiplied motion, in such a manner that the two images taken during the time of taking an ordinary image shall be respectively taken through the two colours, green A and orange A^1 (fig. 1), which gives on a

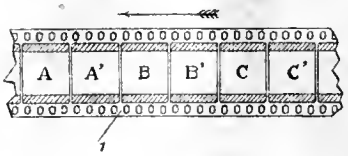

Fig. 1.

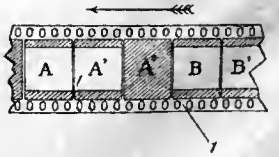

Fig. 2.

panchromatic film, groups A, A^1, B, B^1, C, C^1, etc., of two images for an ordinary one

In the case of the extra rapid taking of photographic negatives where the speed of impression is three times the ordinary one, the multiplying mechanism will be devised accordingly, and the coloured transparent disc comprises three equal sectors, the first one in green, the second one in orange and the third one being opaque, in such a manner that during the time necessary for taking an ordinary image, groups A, A^1, A^0—B, B^1, B^0, etc., consisting of two images and a blank will be obtained, two of which are taken through the two screens respectively, green (A) and orange (A^1) and the other one null (A^0).

The negative film with the images thus obtained is then employed for the production of images on an ordinary positive film in the following manner, which constitutes the second phase of the process.

The printing is effected by projection and not by contact, as shown in the drawing.

The developed negative film 1 passes in the printing machine in a horizontal position, whilst the unexposed positive film 2 is passed vertically, the respective position of the two films being always at an angle of 90 deg. It is also possible to obtain the same result by passing the negative film vertically and the unexposed positive film horizontally.

The arrangement being ensured, the negative 1 is displaced at the

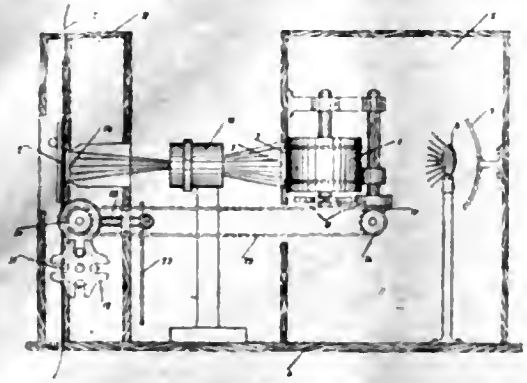

Fig. 3.

rate of one group of images A, A^1 or A, A^2, A^3 for a displacement of a surface of unexposed positive film 2 corresponding to the surface of one ordinary image, in such a manner that the projection by reduction gives the two successive reduced images A, A^1, B, B^1, etc., of each group on the surface corresponding to that of an ordinary image, on the unexposed positive 2, whilst the null image A^2—B^2, etc., in the case of groups with two images and a blank remains out of the projection.

The positive film 2 obtained by the printing method has the horizontal lines in the images transverse to the length of the film as in an ordinary positive film. As shown in fig. 6, each surface 3 corresponding to that necessary for an ordinary image comprises in

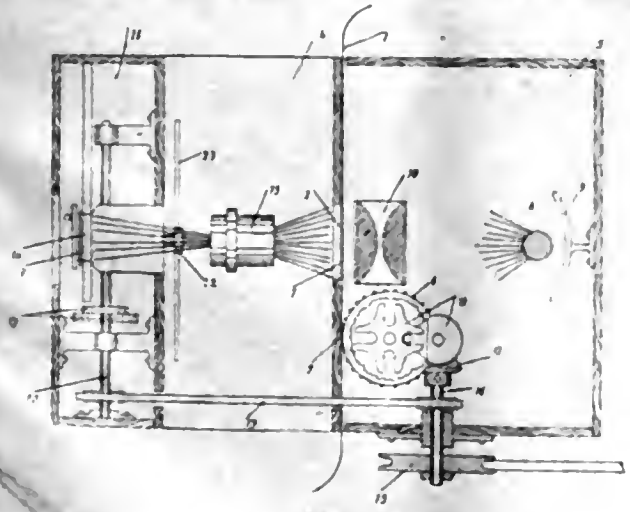

Fig. 4.

this case the two reduced successive images A, A^1—B, B^1 of each group, arranged side by side, in the direction of width of the film, which allows, for projecting purposes, to pass the film as this is done with an ordinary film, that is, vertically.

The printing by projection is effected by means of a printing apparatus consisting of a box or frame 4, enclosing the mechanism (figs. 3, 4 and 5).

A mechanism for causing a horizontal displacement of the negative film 1, by means of a toothed drum 6, is arranged in a back compartment 5, the images being projected through the window 7, by means of any kind of luminous source 8 with reflector 9 and condenser 10.

A mechanism for causing a vertical movement by means of a toothed drum 21 of the positive film 2, which is to be exposed, is arranged in a front compartment 11. The light-rays projected through the negative images by the objective with diaphragms 13 arranged between the two compartments 5 and 11, act upon the film 2, through the window 14.

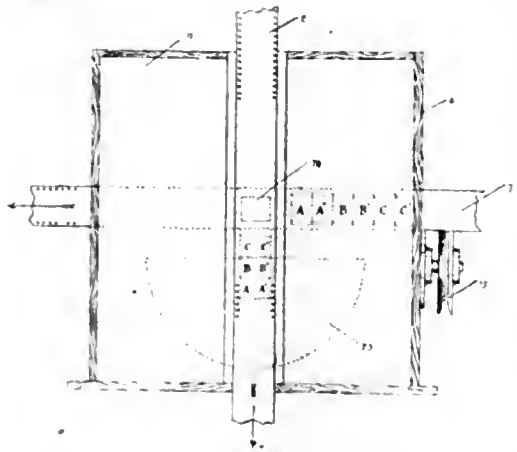

Fig. 6

The means for causing the movement of the drums 6 and 21 are actuated, by any kind of motor, through the pulley 15, the axle 16 of which actuates directly the mechanism by a Maltese cross 18 of the drum 6 by means of bevel pinions 17, and indirectly by means of an endless chain 19, the shaft 20 operating the mechanism by a

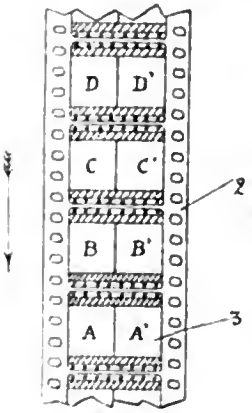

Fig. 6.

Maltese cross 12 of the drum 21, mounted below the shaft 20, the same shaft 20 operating also, by means of bevel pinions, the axis 22 of the obturating sector 23 during the motion of the two films 1 and 2, which motion is calculated so that the positive film 2 shall be vertically displaced in front of the window 14, through a space corresponding to that of an ordinary image, whilst the film 1 (the

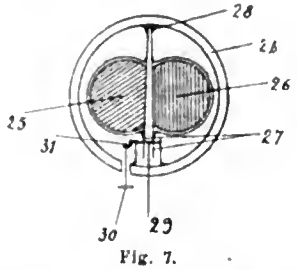

Fig. 7.

drum 6 of which has a larger diameter than that of the drum 21) is horizontally displaced in front of the window 7, through a space equal to two consecutive images A, A^1—B, B^1 or three images A, A^1, A^2; B, B^1, B^2 of each group, the null image remaining non-projected by giving, for this purpose, suitable dimensions to the window 7.

The driving may be effected by means of mechanism, provided with clutches or with eccentrics without affecting the method of printing, and also modifications in the details may be made, the printing apparatus described being by way of example only.

The clearness of the reduced images is not diminished when the positive film 2 is thus obtained.

For projecting the positive film an ordinary projecting apparatus is sufficient, it only being necessary to remove the ordinary objective and to replace it by a special objective which is mounted in its place. Fig. 7 shows a front view of this objective.

The objective comprises a cylindrical mounting 24 inside which two coupled objectives 25 and 26 are mounted, the lenses of the objectives being cut in such a manner as to enable their axes to be brought nearer to each other so that they are separated by the exact distance of the centres of the two images A, A^1—B, B^1, etc. An adjustment is effected by mounting each objective on a kind of double middle partition 27 with a hinge 28, the variable distance of which is operated by a micrometric screw 29 by means of a knob 30 with bevel pinions 31. Each of the objectives which may be mounted in such a manner that their axes shall be slightly convergent, has a special screen, one coloured in green, the other one in orange.

Owing to the arrangement, when projecting the positive film 2, the two images A, A^1—B, B^1—C, C^1, etc., are simultaneously projected on the screen, and are superposed so as to give one image only in natural colours.

RISE AND PROGRESS OF THE TECHNIQUE OF COLOUR PHOTOGRAPHY.

Under this title a demonstration illustrating the history of colour-processes was given by Mr. F. J. Stoakley, F.C.S., at the Camera Club on February 23. Mr. Stoakley showed a remarkable series of colour-slides as examples of both current and obsolete processes. The following note of the lecture is considered worthy of record on account of the simple manner in which the subject was treated.

The meeting was first reminded that colour is not a substance but a sensation, and in order that there should be colour there must be light. When light falls on an object it is seldom entirely reflected. More commonly a portion of the light is absorbed by the object, and the remainder is reflected to the eye, where it produces the sensation of colour. After a few words on well-known phenomena of the continuous spectrum, such as that produced when light is passed through a prism, and the reconstitution into white light by a second superimposed spectrum formed by a prism turned in the opposite direction, the speaker then asked the simple question, "Why does a red rose appear red?" As white light is composed of a mixture of the colours of the spectrum, and a red rose absorbs all the colours except the red rays (or, say, orange), it follows that the rose must appear red, for redness is the only sensation aroused in the eye. Now, suppose that a red rose be looked at through a piece of green glass, the rose no longer appears red, but, on the contrary, it appears black, i.e., colourless. What has happened here is that the green glass has absorbed the reflected red rays from the rose, and the net result is that between the red rose and the green glass all the colours of which the original white light was composed have been absorbed. A similar reasoning applies to the case of green grass. Green grass absorbs all the colours of incident light except green, and if we look at green grass through a red screen the latter absorbs the green rays so that the grass appears black. We know that in both cases the objects have not in reality changed in any respect, and consequently we may assume that the phenomenon of colour is due to absorption.

The earliest attempts to produce photographs in colour were made by what is called the "additive process," that is, the process which depends upon the addition of coloured lights to one another. At this point it is necessary to note that the colour resulting from the addition or mixture of coloured *lights* is quite different from the colour produced by a mixture of several *pigments* of the same colours as the lights. Thus, a mixture of a blue pigment with a yellow pigment is green, but the mixture of a blue light with a yellow light is practically white. The speaker had not with him the apparatus necessary to prove that all the colours of Nature can be simulated by varying the proportions of mixtures of the "primary" colours, and he merely recalled the fact that these three primary colours are red, green and blue-violet.

In 1861 Clerk Maxwell succeeded in reproducing photographically (and projecting on a screen) a piece of coloured tartan ribbon. He made three negatives, one through a red screen, the second through a green, and the third through a blue-violet (or rather a deep-blue) screen. From the negatives so obtained he prepared three positive transparencies, and these were projected on to the "collecting" screen by means of three lanterns, each transparency having its own "taking screen" in front of it, with the result that the colours of the tartan ribbon were approximately reproduced. Similar work on these lines was carried out by Von Hubl, F. E. Ives, etc. The beautiful and ingenious Ives' "Kromskop" gave stereoscopic reproductions in colour based on the principles of the Clerk Maxwell process, viz., the additive process.

The next great step was the development of the additive method so that a single plate could be used instead of the three hitherto employed. This was effected by preparing a plate in such a way that it was in reality an enormous number of tiny screens comprising the essential colour sensations. The tiny colour-screens were composed of regular rulings or patterns of the essential colours on the plate, but this method of tiny screens was further extended to plates with irregular markings. Hence the plates of this type can be grouped under two heads (*a*) and (*b*). (*a*) The Regular: exemplified by Joly's "ruled-line screen," the "Thames" (Finlay), the "Omnicolore" (Jougla), the "Dioptichrome" (Dufay), the Paget Process, etc., the tiny screens of which consist of coloured lines, squares or dots in various patterns in the three colours red, green, and blue-violet, all over the plate.

(*b*) The Irregular: exemplified by the Lumière Autochrome plate, which is prepared by dusting on to a tacky glass plate grains of potato starch which have been previously dyed red, green and blue-violet, and dried and mixed in the proper proportion of colour.

In both cases the screen part is varnished for protection and coated with a panchromatic emulsion. Since this emulsion is more sensitive to blue and violet rays of light than to orange and red it is necessary to use a compensating screen.

Mr. Stoakley showed examples of each screen and micro-photographs of the several screens were projected on to the lantern screen, as well as colour-photographs by the various screen processes. Attention was called to the great superiority of the "irregular" screen for depicting fine shades of colour, metallic surfaces, the sheen of birds' feathers, etc., and the physics of the phenomenon was described. The portrayal of black and white through colour-screens was also shown.

The last process described is that known as the "subtractive" method, as exemplified by the Sanger-Shepherd and its modifications, which have a wide application. Three negatives are made in succession through the red, green and blue-violet screens, and from each of the negatives, or "colour sensations," a positive is prepared. By chemical treatment (or dyeing) the positives are made in the complementary colours of their "taking screens." Thus the positive from the red sensation is made cyan-blue, that from the green sensation is made pink, and that from the blue-violet sensation is made yellow. Two of the positives are taken on gelatine films so that all the positives can be bound up together and projected or viewed by transmitted light so as to reproduce exactly the colour of the original.

The speaker showed a number of slides made by this process, and by means of partly made slides, i.e., slides with 1, 2 or 3, or 2 only, of the combinations of the colours, demonstrated the synthesis of the process and described in detail the precautions necessary to get the best results. The causes of failure or defects were also explained.

The preparation of colour-prints for book-plates and advertisement illustrations depended on making three negatives as above described, and from them blocks were made and inked up in the three complementary colours which were superposed on a white background.

A CHRONOLOGY OF THE PHOTOCHROMOSCOPE.

It would seem desirable, in the interest of correct historical record, to give a summary of the *facts*, as evidenced by the literature available.

First, as to the invention of the word "photochromoscope." J. Francis[1] thus termed an instrument he had devised for examining lantern slides, which was exhibited at the Photographic Exhibition in 1879. This consisted of a tube with enlarging lens, a slot for the slide, a ground glass, and a flexible curtain with graded colours for tinting the picture; this curtain being adjustable by means of a knob. Incidentally it may be remarked that he wrote, claiming priority, because he thought that his idea was being "cribbed by a Yankee"; but the Yank, who was E. L. Wilson, the editor of "Wilson's Photographic Magazine," repudiated any such intention, and abandoned his projected patent.

As regards the instruments used for colour photography we again meet with the fact that Ducos du Hauron and Chas. Cros were the original inventors, and quite independently of one another, as they were of so many other ideas, which have since been patented and exploited by others, without any credit to these pioneers.

It is probably well known that du Hauron sent, in 1862, a paper to M. Lelut with a request that it be read before the Académie des Sciences, and that this paper was rejected; but was reprinted in 1897.[2] And here he described a photochromoscope, with figure, a rough sketch of which is reproduced. It is unnecessary to give in detail du Hauron's description, as its construction will be apparent to anyone conversant with such instruments. Suffice it to say, that the three mirrors, shown in continuous lines, are at right angles

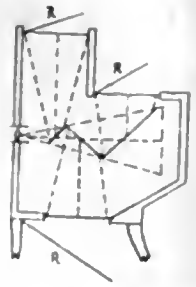

Fig. 1.—Du Hauron's 1862 Photochromoscope

to one another, and the paths of the rays from the three transparencies are shown by the broken lines, as is also the position of the compound image at the extreme right. R, R, R represent adjustable mirrors for illuminating the pictures. Du Hauron suggests that it is possible to modify the results by varying the colour of any positive, locally or entirely. Also that the instrument could be used for stereoscopic work by merely doubling the length of the apparatus so as to enable stereo transparencies to be used. Further, it can be says, possible to use only three single positives

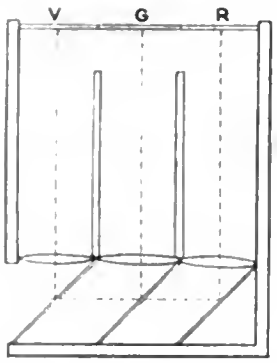

Fig. 2. Du Hauron's 1869 Photochromoscope.

with less perfection it is true (*avec moins de perfection il est vrai*), by arranging for the one eye to see the red and yellow proofs, and the other eye to see the blue. A method, which is physiologically unsound, but which was subsequently patented by Lumley, Barnard and Gowenlock, in the Kromaz, and by Nachet.

Again, in 1869, du Hauron[3] says, "if the images of the three proofs are projected on to a white surface by means of three lenses, placed in such a way that the three images will be exactly superimposed, there will appear on the screen a polychrome image, which is the faithful representation of Nature. To fuse the three proofs into one picture, one may replace the polyoramic apparatus with three lenses by an apparatus composed of three unsilvered glasses (*trois glaces sans tain*), placed one behind the other with respect to the eye of the observer, on each of which there will be by reflection a different picture. To avoid the doubling of each image from the two parallel faces of the corresponding glass, it is necessary to place between the pictures and the glass a convergent or divergent lens, the magnification of which should have the effect of placing the picture at such a distance that this doubling becomes imperceptible." No diagram of this instrument was given; but

1. B.J., 1880, Vol. 17, 36. Wilson and Henerman ran a photo material business, or stock house as it is called, in Philadelphia, and made a specialty of lantern slides. Wilson's "Lantern Tours of the World" were famous.

2. *La Triplice Photographique des Couleurs et de l'Imprimerie*, Paris, 1897, 449-464.

3. *Les Couleurs en Photographie, Solution du Problème*, Paris, 1869, 54, cf. L. Vidal, "Bull. Soc. Franc. Phot.," 1897, Vol. 44, 225, where he quotes Cros and du Hauron. Incidentally it may be noted that about this time a somewhat acrimonious paper discussion raged between Vidal and F. E. Ives as to the priority of the invention of these instruments, and it is not worth while to record all the ink spilt. In order to save space, translations only of the original passages are given by me.—E. J. W.

later, after recalling his previous, 1869, remarks, du Hauron says: "Here is moreover, a diagram which, still better than the preceding description, will explain all the simplicity of the construction, of which it treats." This I have roughly re-drawn, and it requires no explanation.

In 1874 another camera[5] was patented, which was later embodied in his English patent,[6] and the latter says:—"The rays coming from the subject to be reproduced are received upon a glass unsilvered with parallel faces inclined 45 deg., or thereabouts, in respect to the model and in respect to a first lens, towards which it reflects a part of the above-mentioned rays. The greater part of these rays traverse the first glass, and they are received by a second glass equally unsilvered and with parallel faces also inclined 45 deg., or thereabouts, in relation to the model and in relation to a second lens towards which it partially reflects the rays it receives. Lastly: the rays that this second glass allows to pass are received by a third lens either direct or by interposing a silvered or metallised glass, which reflects nearly all of them. The distance of this first glass to the first lens is equal, or nearly equal (slight discrepancies do not appreciably alter the results), to the sum of the distances of the first glass to the second, and of this latter to the second lens, and it will be equal also to the sum of the distances of the first glass to the third lens (or if a third glass is made use of it is equal to the sum of the distances of the first glass to the third glass *plus* that of that of that third glass to the third lens). In virtue of this arrangement the three images received by the three lenses are geometrically the same."

For reproducing near objects, it is pointed out that the doubling of the outlines of the objects from the thickness of the glasses can be easily remedied by interposing between the said apparatus and the model a magnifying glass, having the effect of placing the subject farther back.[7] The use of a concave lens near the sensitive plate is also described to flatten the field, in both patents the unequal sensitiveness of the plates to the green and violet is pointed out, and it is suggested that this may be adjusted by the use of two or more reflector glasses superimposed and in perfect contact, in front of the green-sensitive plate. But in the French patent it says: "This may be obtained, moreover, if desired, by a single glass of which the silvering (*l'etamage*=plating) may be partially removed, in such a way as to present regular alternation of large unsilvered spaces and smaller silvered spaces.[8]

5. Fr. Pat. 105,881, 1874. The full specification is given in *La Triplice Photographique*, 219.
6. Eng. Pat. 2,973, 1876; given in full B.J., 1877, Vol. 24, 152,163, 181, 212, 238, 249, 259; abst. ibid. 1907, Vol. 54 Col. Phot. Supp., Vol. 1, 6.
7. Du Hauron says, loc. cit. 222, that this magnifying glass is nothing more than a magnifier (bonnette d'approche) recently introduced for ordinary work.
8. This is, I believe, the first mention of partially silvered reflectors, later patented by many others, Ives, Lumière, Sanger-Shepherd, Comstock, Brewster, etc.

In 1885 another camera was patented[9] in which "three small mirrors were juxtaposed one against the other, not on the same plane, but in such a manner as to form three facets, differently inclined, but all inclined at 45 degrees with respect to a virtual plane, to which their backs were turned. This virtual plane being built vertically and the three facets being disposed in a triangle, the two facets at the lower part and the facet at the top reflected the same image, the two first ones into two horizontal cameras, where the sensitive plates were, consequently in a vertical position, and the third into a vertical camera where the sensitive surface formed the floor (*plafond*); the triad of the little mirrors occupied the centre of the system and each of them was inclined at 45 deg. with respect to the objective that corresponded to it."

"*Si defecteuse et si rudimentaire*," as the patentee admits this to have been, it gave him satisfactory results. He points out that the three small mirrors should be preferably of plated glass, metal mirrors, or, better still, glass with a perfectly polished silver coating, or they might be three small prisms with silvered hypothenuses. Presumably du Hauron distinguishes between mere "plated" glass, that is ordinary mirrors, and surface silvered glass, the former being mercury and foil treated.

Cros's idea of a photochromoscope is definite enough, though no figure is given, as he says:[10] "Print separately the three clichés on a sensitive paper or on glass—so as to have the three positives. Coat the positive obtained with the red frame with the same varnish which was used for the glass of the frame. The same for the other two positives, of which the first will be covered with yellow varnish, the second with blue varnish. This done, take two clean glasses. Mount on five independent supports, at the same height, the two white glasses and the three positives coloured as has already been described. Finally try to make coincide the images of two of the three positives formed in each of the transparent glasses with the third positive which one looks at direct through these glasses. It may be convenient to illuminate the positives by mirrors. One may also, by modifying the obliquity of the reflection of the transparent glasses, vary in every proportion the intensity of each virtual image. In repeating this experience, one will find the conditions of detail which will prove the best. These conditions being once fixed, one will deduce the principles of construction of an invariable and definitive apparatus which permits, with the three elementary proofs, of reconstituting by the eye the real picture with all its tints."

A VARIATION OF THE SCREEN-PLATE PROCESS.

[A recent patent specification, No. 175,373, in the name of Miss Florence M. Warner, who some years ago was associated in the Warner-Powrie process, proposes a variation of the separate method of making screen-plate colour transparencies. The exposure in the camera is made upon a panchromatic plate, the emulsion of which is coated upon a three-colour mosaic, preferably of parallel-line pattern. On development a negative in complementary colours is of course produced. From this negative a monochrome positive transparency is printed by daylight or artificial light upon a panchromatic plate, and the positive thus obtained bound up in register with a mosaic colour screen, similar to that used in taking the negative. It is obvious that in this process the panchromatic emulsion of the positive plate may require the use of a compensating filter for the purpose of bringing the printing light into adjustment with the colour-sensitiveness of the emulsion. Thus the process eliminates the use of a loose and separate taking screen at the cost of the necessity for this balance in making the positive transparency.]

The invention has for its object the production of transparent positive photographs in natural colours from a negative taken of a subject on a sensitive plate provided with a permanent colour screen having different coloured elements.

The method is for overcoming the difficulties of the separate and combined screen-plate processes, by which positive transparencies can be made in any number and in natural colours from a negative made on a screen plate having the sensitive emulsion on the screen plate itself.

According to the invention, positives in any number may be made from a negative taken on a sensitive plate having a permanent coloured screen of lines, dots, or figures, by making a monochrome positive from such a negative on a panchromatic plate, so as to produce a good black and white condition, if the positive is taken under what may be termed balanced conditions of light and emulsion. By "balanced conditions" is meant balancing or compensating the sensitiveness of the emulsion and the printing power of the light.

A negative is made on a plate produced by coating a screen plate having a recurring pattern as recurring parallel lines of the three primary colours, green, blue, and red, with a sensitive emulsion, the emulsion being placed directly on the colonred lined surface of the plate so that the screen is permanent, that is, the screen is not removed during the process of development. A screen having a pattern of parallel lines is preferred, though screens having other patterns of regular recurring elements may be used.

As shown in fig. 1, the subject chosen for illustration is a red

Fig. 1.

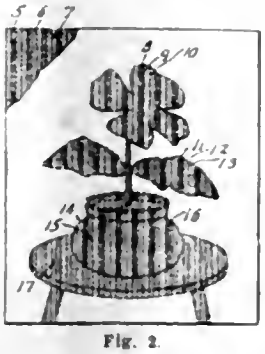

Fig. 2.

flower 1, with green leaves 2, in a blue pot 3, standing on a black table 4. An exposure of this subject is made on a screen plate having alternate parallel lines of red, marked 5, green, marked 6, and blue, marked 7. This exposure is made in a camera equipped with a compensating filter. This negative after exposure is developed and fixed in the usual manner, and there is produced a negative image in colours complementary to those of the subject. These colours are indicated by the lines; the black lines 8 are the lines through which the red lines of the screen have let pass the red light of the red flower 1 and exposed the sensitive coating of the plate. The emulsion over the green and blue lines 9 and 10 has been unacted on so that when the negative has been developed and fixed these lines will appear clear. The same action occurs for the green leaves, the silver emulsion over the green lines in this instance being exposed and being indicated by the blackened lines 11, the emulsion over the blue and red lines 12 and 13 being unexposed; and the same action has occurred in the negative of the bowl, the silver emulsion over the blue lines having been acted on and forming the black lines indicated at 16, the emulsion over the green and red lines 14 and 15 having been unacted on. None of the silver emulsion over the lines back of the black table of the plate has been acted on and the silver is unexposed, this condition being indicated by the lines 17.

From this negative a positive is printed on a plate having a panchromatic emulsion, so as to produce a monochrome having a good black and white condition, that is, in which a true black and white is obtained, and not a black or white tinged with colour. In printing this positive, any source of light may be employed. Preferably this would be an artificial white light, such as that of acetylene gas or the well-known nitrogen lamp. Where the printing is to be effected by such light, the emulsion of the plate will be of such character that it is equally sensitive to the green, blue, and red of the negative screen, and in such case the compensating filter may be omitted in the printing. If, however, the printing is to be effected by natural light, a compensating filter is used, this filter rendering the emulsion equally sensitive to the three colours of the screen, and where such filter is used no change in the emulsion is necessary.

This monochrome positive is then developed and fixed in the usual manner and with the usual developing and fixing agents. After developing and fixing, the monochrome positive appears as shown in fig. 3, the red flower appearing in lines 18 and 19, the lines 18 corresponding to the lines 8 of the negative of fig. 2, and the lines 19 corresponding to the lines 9 and 10 of negative of fig. 2; similarly the green leaves appear in lines 20 and 21, the lines 20 corresponding to the green lines 11 of the negative of fig. 2, and the lines 21 corresponding to lines 12 and 13 of the negative of fig. 2 similarly with the blue pot in which the lines 22 correspond to the lines 16 of the negative of fig. 2 and the lines 23 correspond to the lines 14 and 15 of the negative of fig. 2, and the table 24 is a black silver deposit covering all the lines as shown at 17 of fig. 2.

The positive plate is then superimposed in registered position with a colour screen similar to the screen through which the

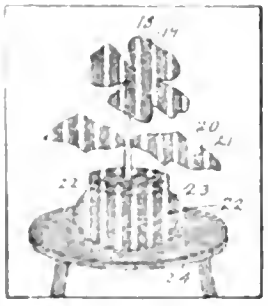

Fig. 3.

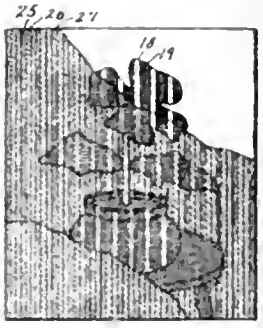

Fig. 4.

negative was taken, such as a lined screen having parallel lines 25, 26, and 27 of alternate red, green, and blue colours. The two plates are superimposed and adjusted with respect to each other and mounted together. When properly adjusted the subject photographed will appear as a transparency in its original colours, and this condition is illustrated in fig. 4. As shown in this figure the monochrome positive and the lined screen plate are so adjusted that the lines 18 of the red portion of the subject are superposed over the red lines 25 of the screen plate, the green lines 20 are superposed over the green lines 26 of the plate and the blue lines 22 are superposed over the blue lines 27 of the plate.

TRIADOCHROME THREE-COLOUR PRINTS BY TRANSFER AND CHEMICAL TONING.

[In the issue of this Supplement for February 3, we published a short account of the process of three-colour printing worked out by Mr. J. F. Shepherd and named by him Triadochrome. The full way to the particulars of the process are contained in the patent specification, No. 175,003, granted to J. F. Shepherd, and [illegible] Photography Ltd.]

This invention consists in improvements in or relating to colour photography, and refers particularly to those methods of obtaining subtractive three-colour prints wherein the three superimposed coloured images are prepared by two or more dissimilar methods. Examples of such methods of obtaining colour-prints which have been proposed are described in the Patents Nos. 1,937 of 1911 and 20,556 of 1912.

According to one feature of the present invention a method of three-colour photographic printing consists in superimposing two chemically toned photographic images and a pigment or dye image, the colours of the three images being those usual in subtractive methods of colour photography; and the colour of the pigment or dye image may be any one of the three.

By "chemically toned image" is meant a coloured image produced by chemical action on an image consisting of metallic silver which is thereby changed completely into a coloured compound;

and by "pigment or dye image" is meant a coloured image consisting of a pigment or dye only and does not include an image produced by chemically treating or replacing a silver image. An example of a chemically toned image is a blue-green image produced from an ordinary silver image by treating it first with an alkaline ferricyanide solution and subsequently with a ferric salt solution.

An example of a pigment or dye image is a colour carbon print, produced as is well known by the hardening action of light on bichromated gelatine impregnated with a pigment or dye. Another example is an imbibition image, produced by imbibition or absorption of a dye by a gelatine from a dyed printing-plate. Further, an image produced by mechanical printing in colour from a half-tone block is also regarded as within the scope of the term "pigment or dye image."

As an example of a method according to the invention, there may be superimposed in register on a positive magenta carbon print, two bromide prints chemically toned respectively to the colours required for the blue-green and yellow positive images. If desired, the colour-tone of the magenta image may be modified by the immersion of the positive magenta carbon print in a solution of flavazine or naphthol yellow, or a combination of flavazine and naphthol yellow. Moreover, the blue-green and yellow positive prints are treated with toning solutions which can preferably be modified to vary the colour-tone of the resulting print.

According to one method of carrying out the invention one of the superimposed bromide prints is stripped, during the process of superimposition, from its backing, and the other bromide print is superimposed as an outside element of the composite photograph, the original paper or equivalent backing of that print remaining as the backing for the composite photograph.

Another feature of the invention comprises a method of three-colour photographic printing which consists in superimposing in register two chemically toned colour positive prints and impressing the third image—that is, the pigment or dye image—in register on either one or the other of the prints before or after superimposition by means of a dyed printing plate.

By the term "printing plate" is meant any surface so formed or produced as to retain pigment or dye to different extents at different parts thereof and to transfer the pigment or dye to the surface upon which it is to be impressed. Thus, for example, such a printing plate may be a bichromated gelatine surface exposed through a photographic negative as used in the so-called "imbibition" method; or it may be a half-tone printing block of the ordinary kind.

Some preferred methods of carrying the invention into effect will now be described in detail by way of example only.

In the first method now to be described three-colour record negatives of the object are obtained in the manner well understood in three-colour photography. The positive print, of which the image is to be a magenta or minus green colour, is obtained from the appropriate negative by printing on a magenta carbon tissue. Positives are printed from the other two negatives as black and white prints on bromide paper, conveniently of the kind which is sold and known as "Transferotype" paper. Such paper is a bromide emulsion paper specially prepared so as to be capable, after printing, of having the backing paper stripped off from the emulsion during the transfer process.

The black and white bromide prints are chemically toned respectively blue-green and yellow, or, in other words, minus red and minus blue respectively. For the "blue green" print the following toning solution is preferred:—

Potassium ferricyanide	½ oz.
Ammonium citrate of iron	½ oz.
Citric acid	1 oz.
Water	60 ozs.

In practice the bromide print for the blue-green image is preferably transferred in its black and white condition on to the magenta print and after being so transferred is toned to the blue-green colour with the solution above described. The toning of the blue-green image does not affect the magenta image during the process of toning. For this purpose the black and white bromide print is superimposed on the magenta carbon image and allowed to set for about one hour, after which period the paper backing is stripped off conveniently by soaking in water at a temperature of about 85 deg. F. The backing is found then to be easily removable and the blue-green toning is effected after the backing has been stripped off.

The yellow print is preferably toned before superimposition, and a solution for toning this print is prepared preferably as follows:—

STOCK SOLUTIONS.

(1) Mercuric iodide, 5 per cent. solution; (2) Potassium iodide, 5 per cent. solution; (3) Potassium ferricyanide, 3 per cent. solution. admixed with ammonium bromide, 3 per cent. in equal proportions.

To make a yellow toning solution for use—

3 ozs. of No. (1) stock solution.

4 ozs of No. (2) stock solution.

8 ozs. of No. (3) stock solution are admixed with 10 per cent. water.

After toning the print should be washed well for about 20 minutes.

The carbon print is first transferred on to a glass, celluloid or other transparent support and, in the manner described, the other two prints are superimposed in register thereon in succession. The last print to be superimposed does not have its backing stripped from it, but the composite print is stripped from the transparent mount leaving the backing of the last applied print as the backing of the finished photograph.

Alternatively the backing of the last applied print may be stripped off and the coloured photograph used as a transparency. It is immaterial in which order the prints are superimposed, but if the paper backing of one of the prints is to remain as the backing of the finished photograph, that paper backing should be the original backing of one of the bromide prints.

The process adapts itself to reproduction on a large scale of coloured prints from the one set of negatives, but it is found that if the prints are not to be superimposed immediately surplus moisture should be blotted off at least from the bromide prints and the prints allowed to dry as rapidly as possible. These prints can then be laid aside until they are required for making up the composite picture, when they will be soaked in water before being transferred and superimposed one on the other.

In another method of colour printing according to this invention blue-green and yellow toned bromide prints are prepared in the manner described above. The blue-green print is conveniently transferred to a celluloid or other transparent support and its backing stripped off. The yellow print is then superimposed in register over the blue-green print, is squeegeed thereon and when dry the prints are pulled off from the support and remain on the paper backing of the yellow print.

The magenta print is obtained by making a black and white positive transparency from the green record negative and from the positive so produced a print is made on a bichromated gelatine film which is transferred to any desired backing and soaked, either before or after transference, in a magenta dye. As is well known, this bichromated gelatine film absorbs dye more readily in those parts which have not been exposed to light, and consequently when the two-colour print already made is squeegeed into contact and in register with the dye-soaked film, a magenta dye image will be transferred to the print by imbibition, thus completing the three-colour print.

It is immaterial to the invention, in what order the prints are superimposed or impressed provided that any one of the three-colour images which is opaque in character is next to the paper or other backing.

PRACTICAL COLOUR PHOTOGRAPHY.—The American Photographic Publishing Co., 428, Newbury Street, Boston, Mass., announce for early publication a comprehensive treatise on colour photography by Mr. E. J. Wall under the above title. The work is to be divided into nineteen chapters dealing with principles of colour, sensitive plates and colour filters, cameras, subtractive printing processes, colour screen-plates, the Lippmann process, two-colour and other processes as well as with colour cinematograhy. The price of the work has not yet been definitely fixed, but will probably be three dollars. Orders will be accepted in advance of publication at the special price of 2 dols. 50.

SOME CAUSES OF FAILURE IN AUTOCHROME WORK.

The Autochrome process is, I think, rightly regarded as among the simplest of the present-day methods of producing photographs in natural colours, and though the manufacturers of the Autochrome plate give specific and minute directions for their manipulation, many photographers, even after a fairly lengthy experience, do not obtain results as good as the process is capable of giving. Hence some notes on causes of possible failures may perhaps be of use to many workers, who may not have obtained strikingly beautiful results.

One of the most prolific causes of failure in securing Autochrome transparencies pleasing as regards brilliancy and rendering of colour can be traced to the fact that many exposures are made under dull lighting conditions. The light in this country, even at its brightest, is none too good for colour photography. Under dull lighting conditions, while the plate may render the colours up to a certain degree, the visual brightness that we associate with the subject is lacking: the transparency looks dull and spiritless. It is not generally realised by those who have not had a grounding in the scientific principles of colour that the brilliance of the colouring in any object depends almost entirely upon the strength of the light illuminating it. If, for example, we examine a deeply coloured orange in a shadowed corner of a room we shall be sensitive of its colour in only a slight degree. If we take the same orange to a more brightly lit part of the room near a window we shall be impressed by its colour still more; while if we take the same orange into bright sunlight its colouring will be more brilliant still. I would go so far as to say that the orange when examined in the dark corner of the room looked almost *colourless*, and probably the impression as to its colour was a *mental* rather than a *visual* one. The colour of the orange was known, and this fact influenced to a great extent the idea formed of its intensity of colouring. By way of emphasising this point still further, if the orange is placed upon a table near a window, the light coming from one main direction, it will readily be observed that the colour is more intense where the light is strongest, while on the extreme shadow there is little or no colour visible. It is there of course, but the light has not brought it out. Now a colour photograph taken of this orange would be unsatisfactory. There would be a small area of colour upon the orange, the rest being in shadow, and, reflecting no coloured light-rays would be seemingly inaccurate. The picture would be accurate, but as a colour photograph distinctly unpleasing. If the Autochrome worker can only grasp this point fully at the outset he will go far to avoid one of the most prolific sources of failure. I do not mean to infer that it is not possible to make quite good Autochromes under dull lighting conditions, but rather that the best results are certainly only to be obtained under the most brilliant lightings. We are so used to thinking of the brilliance of the colours when viewed under sunlight that we do not fully realise what a great difference an absence of sunlight really makes.

Further, it seems that the very weak light-rays emanating from shadow detail cannot pass through the screen of an Autochrome plate unless a very full exposure can be given, a fact contributing towards lack of colour in the deep shadows. In this respect the average Autochrome rendering of a sunset is often disappointing. There is a central spot of colour in an area of black shadow, which, though satisfactory from the scientific point of view, fails to please as a picture. I would most strongly emphasise that all exposures should, as far as possible, be made out of doors, even when taking Autochromes of flower, fruit and still-life studies, for unlike monochrome work, where we need shadow and tone, the Autochrome needs colour, and the strongest possible even lighting is required to bring this out and avoid contrasts.

The question of exposure, where so many workers go wrong, is best settled by a careful calculation with an actinometer that makes an actual test of the light, the indicated exposure being very accurately timed. Ten per cent. of the time may be added with advantage if the light is dull or with a view to allowing for any slight lessening of the speed of the plate after its manufacture. Many Autochrome transparencies that I have seen bear abundant evidence of the fact that the question of the exact exposure has not had the amount of attention necessary.

As regards dark-room manipulation, the safe-light recommended by the makers should always be used; and this requires to be most carefully employed if it is not to affect the colour of the Autochrome plate. I have seen many Autochromes possessing a greenish blue tint that has very obviously resulted from too close an inspection by the Virida light. This should be kept at least 4 feet from the plate, the latter always being shielded from direct rays.

I recommend that whenever the exposure is known to be correct the plates should be developed in a tank by a reliable time and temperature system. This will produce far better results as a general rule than the old method of judging the

process of development by inspection. In fact, even after a considerable experience this is no easy matter, and incorrect development may be regarded as a very prolific cause of failures, even when the exposure was correct. Using the highly concentrated solutions recommended for Autochrome plates, the image appears very rapidly, and the plate quickly begins to blacken over. Owing to this fact and the necessarily weak dark-room light, the degree that development has progressed is not easy to judge. Even if tank development is not adopted, the time and temperature system should be employed. The chief danger is under-development in the first bath. If this happens, the first image, being weak, leaves too much unreduced silver after reversal, with the result that after the second development the Autochrome is dull, opaque and lacking in brilliancy of colour.

Trouble sometimes arises from a lack of understanding upon the part of the photographer that an Autochrome film is far more delicate than an ordinary dry plate, and will not stand rough washing; prolonged immersion, in solutions, or solutions of abnormal strength, handling with hot fingers, etc., without risk of mechanical damage. The film must not be touched while wet with the fingers. If proper cleanliness of solutions, dishes, etc., is observed there should be no need for this.

An otherwise good Autochrome may be spoiled through needed after-treatment being postponed until the plate has dried. If an Autochrome transparency, after the second development, is found to need intensification or reduction, this should be proceeded with at once, for if the plate has once been dried re-wetting is almost certain to produce green spots, if not worse. After-treatment which involves prolonged immersion of the transparency is to be avoided if possible, but my own experience has been that if strict cleanliness is observed, the plate handled as little as possible, and immersed for as short a time as is consistent with the effective action of any solution at normal strength, few failures will occur.

Finally, some Autochrome transparencies, after coming from the second development, are of an unpleasing brownish tint which detracts from the beauty of the colouring. If this is found to be present the reversing bath may be diluted to about one in forty, and the Autochrome, after well washing, immersed in this bath. Great care must be taken not to leave the plate in the solution too long: half a minute at the outside is sufficient to clear the image; longer action may greatly reduce the image. Though not generally regarded as essential, most Autochromes are the better for the clearing bath, especially if the colours are inclined to be dull. The plate should be washed for about four minutes afterwards.

At the present time most of the early difficulties have been satisfactorily overcome, and the production of perfect colour pictures is a certain and simple matter. The makers point out that owing to the extreme delicacy black spots do sometimes appear in the emulsion, but in my own case it is rare to find them, and as a general rule if a plate gives an unsatisfactory result the worker himself is usually to blame.

ROBERT M. FANSTONE.

A CHRONOLOGY OF THE PHOTOCHROMOSCOPE.

(*Concluded from Page* 14, *Supplement.*)

Of course it may be said that this description is so vague that it cannot be advanced, from a patent standpoint, to anticipate anything; but Cros, later, was more explicit, and in a communication to the Société Française de Photographie[11] he describes in detail a "chromometre," which admits of no cavilling. It is unnecessary to reprint his preliminary observations in full, and we can summarise them by saying that he recognised the fundamental triad, "already published by M. Helmholtz," of red, green and violet;

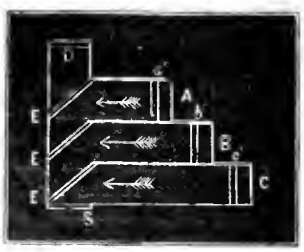

Fig. 3.—Cros' 1879 Chromometer.
A. B. C. Positive images on glass obtained with different coloured rays. *a' b' c'*. Grooves for troughs of coloured liquids to be placed in conjunction therewith. D. Ground glass. E E E. Transparent plate glass screens upon which are projected respectively the images of A B C. S. Spectator, who sees the three images of different colours coalesced into one image.

that he used glass troughs filled with a red solution of cobalt chloride, a yellow solution of neutral chromate of potash and a blue solution of copper nitrate, and combined them to obtain the correct triad. He then says: "For a more handy presentation before the Photographic Society of France I have replaced these systems of troughs by glasses coloured respectively violet, green and orange by means of collodion tinted with aniline colours. I have called this instrument a 'chromometre,' because it can serve to distinguish the colours one from the other by numerical denomination. In fact to vary indefinitely the tint resulting from the visible field, it suffices to vary the force or amount of lighting of each opening. I propose to employ the method of Arago by polarised light, but I cannot afford the construction of such costly apparatus. I must content myself with the instrument I have already had constructed, and vary the lighting by the interposition of thicknesses, more or less numerous, of transparent paper. One of the most curious applications of the chromometer is the following:—I obtain three negatives reproduced from any coloured picture—the first negative through a green, the second through a violet, and the third through an orange medium. The media are, again, the parallel-sided troughs of plate-glass containing standard coloured solutions. I may here remark in passing, that the inequality of actinism of these different lights is completely compensated by various organic substances with which I impregnate the sensitive plates. The negatives obtained are formed of reduced silver-like ordinary negatives. I obtain the black positives from these negatives, and I place each of these positives in the chromometer before the same medium of the same colour as that which served to obtain the corresponding negative. I make the three reflections to coincide, and the resulting image is that of the coloured model picture when the force of the three illuminations has been properly arranged."

It is evident from the above that we have the fundamental ideas of all subsequent photochromoscopes, and anticipation of several patented details.

Later Instruments.

Turning to modern instruments, if one can call modern those which are in some cases more than a quarter of a century old, the Patents Chronology of the "B. J." of 1907, Vol. 54, gives an

11. *Compt. Rend.*, 1879, Vol. *88*, I., 121; Bull. Soc. Franç. Phot., Vol. *26*, 23; Phot. Times, 1879, Vol. *9*, 186; B.J., 1879, Vol. *26*, 29; also described with similar figure in Phila. Phot., 1879, Vol. *16*, 90, by E. Stebbing, who was the French correspondent of this journal. Ives' patent for a three-step chromoscope is U.S. Pat. 531,040, 1894; corresponding Eng. Pat. 2,305, 1895.

abstract of the English patents; it is unnecessary, therefore, to repeat these, and only such additional references will be given with regard to the same as may round out the information, and the page number refers to the said chronology. But there are a few additional instruments, which can be interpolated by anyone interested in the same.

A. H. Cros, p. 6, also Fr. Pat. F. E. Ives, p. 15, same as U.S. Pat. 475,084 and Fr. Pat. 222,121, 1892.

C. Zink[12] also made a photochromoscope, although apparently it was not patented, and H. Krone gives the following data:—In the spring of 1893 Carl Zink, a photographer of Gotha, without knowing the photo- or heliochromoscope of Ives, constructed an apparatus which could be used for the same purpose, which he called a "photopolychromoskop," and which on account of the greater simplicity in its arrangement appears capable of acting as Ives' apparatus. In the exhibition of the 23rd Convention of the Deutscher Photographenvereins in August, 1894, at Frankfurt a/M., Zink exhibited for the first time an example of his photopolychromoscope, and, after testing, it was awarded the silver medal by the prize committee of the Convention. It is again unnecessary to enter into the details of construction, as this is clear from the accompanying diagram, a copy of that given by Krone. It will be sufficient to state that the filters V, G, R represent the violet, green and red respectively, and that 3 was a silvered mirror, the other two being plain glasses; and the eye E saw the composite image at I. It is also suggested that the instrument might be used as a camera, by inserting dark slides in the three steps, and that the green filter should be replaced by a yellow one. Further, that it might be used for projection by fitting it with three condensers and three small arc lamps; that it had the advantage that only one objective was used and there was no doubling of the outlines.

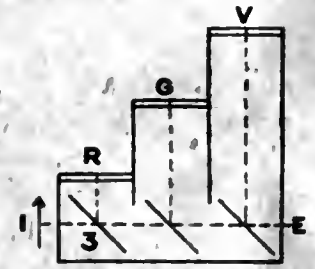

Fig. 4.—Zink's Photopolychromoskop.

C. Nachet[13] constructed several instruments; a stereophotochromoscope, fig. 5, and two of the positives were placed opposite the lenses, whilst the third, the green, was placed at the bottom of the instrument, its image being combined with either the red or blue by the platinised mirror. Niewenglowski states that Nachet obtained the idea for his instruments from Vidal's lectures at the Conservatoire des Arts et Métiers in 1891. Nachet[14] also made two cameras, figs. 6 and 7, and it will be noted that the latter is practically the same idea as White's camera of 1896, dealt with by Commander Rendall.

Niewenglowski[15] conceived the idea of increasing the usefulness of Nachet's stereo instrument by fitting it with analysers and polarisers, fig. 8, in which P is a pile of glass plates and N the Nicol prism or another pile of glass. Variations of colouring were thus obtainable by merely rotating the Nicol; the date of this must be 1894 or early 1895.

Ducos du Hauron[16] designed two cameras, one, fig. 9, was for one plate and was fitted with two transparent reflectors at an angle of 55 deg. to the optical axis, which reflected the rays to the three silvered mirrors M, M, M, and thus gave equal optical paths for the three images. In the other type the advantage of a single plate was sacrificed to compactness, fig. 10, and here two transparent mirrors at right angles were used, the first face reflecting the rays to the silvered mirror M, thus also equalising the paths. These instruments were called "chromographoscopes" and could be used as cameras as well as chromoscopes for viewing the results.

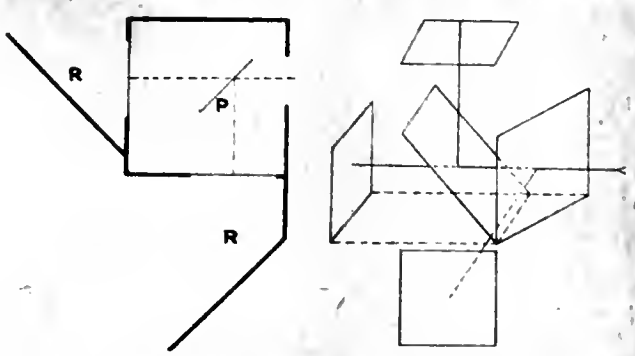

Fig. 5.—Nachet's Stereochromoscope. Fig. 6.—Nachet's Camera.

Ives, p. 16, same as U.S. Pat. 546,889, 1895; and p. 24, same as U.S. Pat. 531,040, 1894. He also patented[17] the insertion of a second plate of glass between the transparencies and reflectors to correct distortion, and claimed wedge-shaped reflectors. In a later patent[18] a camera is claimed in which the images are obtained on one plate by means of six reflectors, and tilting the camera to an angle of 45 deg. by means of a block of wood.

Du Hauron, p. 56, this camera was called the "melanochromoscope," and corresponds with U.S. Pat. 686,897, 1901, and Fr. Pat. 288,870, 1899.

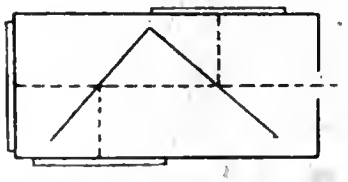

Fig. 7.—Nachet's Camera.

Ives[19] used three primary parallel reflectors one behind the other, and three reflecting prisms in front of three lenses; the camera obviously having to be angled as regards the subject; the plate being at an angle of 45 to the axial ray of the primary reflectors, and the prisms at an angle of 67.5 deg. to the said axial ray.

Selle[20] patented a camera and chromoscope, in which two central mirrors at right angles to one another reflected the rays to secondary silvered mirrors above and below; the central optical path being equalised by an inserted lens.

Ives[21] used a primary reflector at an angle of 45 to the incident ray, and behind this two right-angled prisms with their bases cemented in contact, this contact surface being either thinly silvered or with opaque metal reflecting surfaces broken into lines, dashes, dots, etc. The images were received by three lenses for three separate cameras placed on three sides of a square.

14. Bull. Soc. Franc. Phot., 1896, Vol. 42, 564; 1896, 312.
15. *Les Couleurs et la Photographie*, by G. H. Niewenglowski and A. Renault, Paris, 1896, 361.
16. C. L. Rockert, loc. cit., 169; *Bull. Soc. d'Encourag.*, 1899, Vol 98, 368.
17. U.S. Pat. 635,263, 1899.
18. U.S. Pat. 666,712, 1900.
19. U.S. Pat. 668,989, 1901.
20. Eng. Pat. 12,514; Fr. Pat. 322,840, 1903. This was very similar to Eng. Pat. 13,666, 1899; abst. Col. Phot. Supp., 63. Ger. Pat. 120,982, 1899, corresponds to this last patent.
21. U.S. Pat. 703,929, 1902. Lined silvered prisms were patented by Sanger-Shepherd, Eng. Pat. 10,992, 1902.

Krayn[23] introduced a two-step chromoscope with adjustable mirrors externally to vary the illumination of the pictures. He also[23] patented the linking together of the transparencies so that they would automatically fall into position on the chromoscope. Also, he patented[24] the adjustment of the reflectors in a two-step instrument by fastening them rigidly into a frame that slid along the base of the instrument.

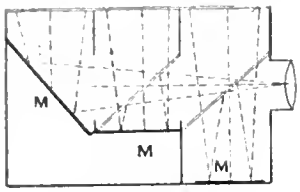

Fig. 9.—Du Hauron's Chromographoscope.

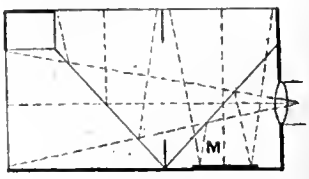

Fig. 10.—Du Hauron's Chromographoscope.

Ives[25] patented the use of bent springs engaging with the ends or sides of the reflectors to alter their figure.

This seems a convenient point to close up. It would be possible to include later forms, but these have been dealt with almost entirely in the Colour Supplement of the "B. J." since 1907. I have refrained from commenting on the obvious similarities of many of the ideas, as it would probably lead to needless discussion, and anyone interested in the subject can draw his own conclusions, and refer to the original sources if thought desirable.

25. U.S. Pat. 622,480, 1899; also patented by A. Strauss-Collin, Ger. Pat. 102,206, 1898.

REFRACTION COLOUR SCREEN-PLATES.

The following is the process described by M. Albert Keller-Dorian, of Mulhouse, Alsace, France, in a patent specification No. 158,511, applied for under the International Convention on January 21, 1920:—

It is known that total reflection from the inner face of a refracting medium can take place only when the said face is separated from a medium of the same refractive index, by a distance equal at least to one-quarter of the wave length. It follows that if at the back of the reflecting face a surface is arranged of the same refractive index, the distance of which increases from zero to the greatest wave length of the visible spectrum, the following effects are obtained:—

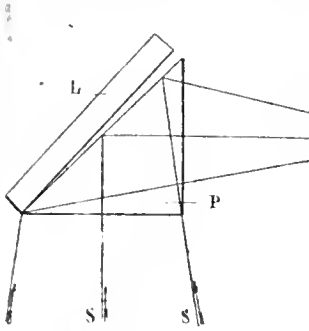

Fig. 1.

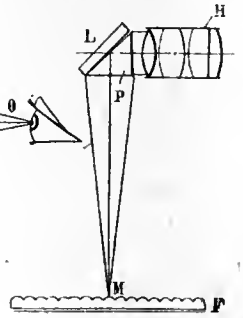

Fig. 2.

(1) At the points where the distance is less than one-quarter of the length of the smallest visible wave, no reflection will take place, and an impression of black will be produced;

(2) Beginning from the point where the distance becomes greater than the said minimum, the colours of the spectrum will be seen to succeed each other from violet to red;

(3) Finally, if the distance increases beyond the quantity required for reflecting the red rays, a second spectrum (spectrum of the second order) will be seen to succeed the first one, and so on, until the colours merge into white light.

According to the invention, apparatus producing these phenomena is used for the polychrome selection required in certain colour photography processes, namely, in those which are based on the use of sensitised surfaces mounted on a substratum provided with microscopic refracting elements.

This process is based on obtaining, on the sensitised layer, as many elementary images of the disc of the camera lens as there are microscopic refracting elements in the substratum of the sensitised layer. In order that the process should result in a polychrome selection of the radiations emanating from the object, the radiations of different colours must pass through the camera lens at different points. In the Berthon process, the disc of the camera lens is covered by suitably arranged three-colour selection screens. This device has the drawback of using screens which are necessarily arbitrary in colour and which falsify the natural colours.

The present invention consists in the combination with a sensitised plate having microscopic refracting surfaces and a camera lens, of a reflecting device comprising relatively inclined surfaces for the purpose of producing interference, the surfaces being located between the lens and the plate.

Fig. 1 shows an arrangement of the apparatus. At P is a total reflection prism (it could be replaced by a plate with parallel faces, but this would result in doubling the image). At L is an optically flat plate located a very small angle with the hypotenuse of the prism. From the point of observation O, the colours of the spectrum will be seen in steps from below upwards, with the plate L inclined, as shown in drawing, and assuming that the light admitted at S S S is ordinary white light.

Fig. 2 shows the arrangement of the same prism P with the plate L, at the back of a camera lens H. In the focal plane is arranged a sensitised plate F with microscopic refracting elements. From any point M of the layer F the disc of the camera lens will be seen in colours reflected by the device P L, assuming, of course, that the lens transmits white light to the point M. If the light transmitted is a monochromatic one, only the portion of the lens corresponding to the reflection of the said colour will appear luminous. If the light is a complex polychrome light, the lens will appear in the form of coloured bands corresponding to the spectrum of the light in question. In fine, each microscopic refracting element of the sensitised plate will register a spectro-photograph of the radiations striking it. Chromatic analysis will thus be brought about independently of any arbitrary factor, and merely owing to the properties of the light itself.

It must be pointed out that the device specified is not necessarily constituted by two flat plates or by a prism and a flat plate. The plate can be very slightly convex, and touch the hypotenuse face of the prism in its centre. In this case the colours are arranged concentrically about the black point. They are Newton rings in their original form.

The reflection device above described may be replaced by a reflection device having multiple layers of air similar to that employed in Lippmann's interference spectrum.

Messrs. Routledge announce that a revised edition of the textbook, "Photography in Colours," by Dr. G. Lindsay Johnson, will be published during the present month. The price will be about 6s. net.

Defective Colour-Perception.—A medical man writing in one of the evening papers on the difficulty some people experience in distinguishing colours says:—"One form of defective colour-perception is due to excessive smoking. It is known in pathology as *Tobacco Amblyopia*, and is caused by toxic substances, more particularly tobacco," he pointed out. "It is brought about by disease of the optic nerve, and unlike normal or physiological deficiency, responds to treatment. An over-use of tobacco, aided by mental depression and a low state of health, is the most general cause."

And further: "Some pairs of eyes have secrets between themselves—colour-blindness in one eye. While the right eye may see red as red, the left sees it as black. I have known victims of colour-blindness describe pink silk as sky blue, and scarlet berries as green. Colour-blindness is not generally the outcome of disease, but is usually hereditary. Sometimes, however, like gout, it skips a generation. Patients are super-sensitive about it. There have been many cases where veterans of 70 have hidden colour-blindness from their friends all their lives."

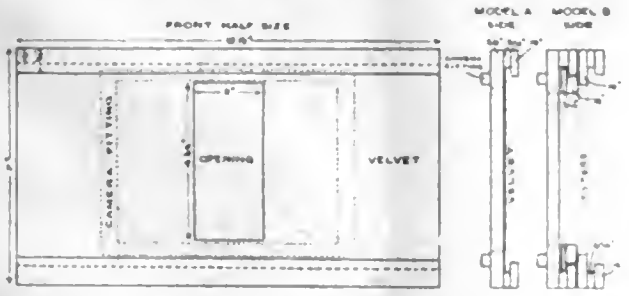
THREE-COLOUR REPEATING BACKS.

Although colour photography has been making fair progress during the last few years as regards the number of photographers taking it up, many have not done so owing to the greater expense as compared with monochrome. This is especially so with three-colour work, for three plates to each exposure soon runs away with the money, and when making a beginning with any process mistakes often occur.

When I started three-colour work myself I found it pretty costly, for an error in one plate meant the scrapping of three, so I looked round for some means to lessen the cost until I became more efficient. To that end I made myself a repeating back to fit my half-plate camera, so that I could make the three exposures on one half-plate. Although not very elaborate or showy it answered my purpose, and I took a considerable number of successful photographs with it.

The materials required are a strip of black velvet or plush, 13 in. by 7 in. One piece of wood 12½ in. by 7 in. by ⅞ in. (three-ply is the best for this); two pieces of wood.



12½ by ½ in. by 3-16 in., and two pieces 12½ in. by ⅞ in by ¼ in. The frame of an old dark slide belonging to the camera to be used will also be wanted, but if no such thing is at hand a fitting must be made so as to attach the back to the camera.

Cut an opening 2 in. by 4½ in. in the centre of the large piece of wood (see diagram), and then glue the piece of velvet, making sure it is perfectly smooth over the surface, turning the two ends over.

When dry, the velvet should be cut out at the opening. The frame of the dark slide or fitting should be both glued and screwed on to the other side of the board so that the hole is central.

The strips of wood should now be fitted on top of the velvet: the narrow strips first and then the wider pieces. Glue them first and then pass screws right through.

The narrow pieces of wood should be rubbed down to the thickness of the rebate on the dark slide intended to be used, and so fixed on the board that the dark slide lies comfortably between them. The top pieces are adjusted so as to hold the slide in place, but allow of free movement.

A mark should be cut in the top strip at the point where the centre of the plate is central with the opening. A thin piece of wood may be glued along one end to prevent the slide from accidentally overrunning the edge. A small catch on the other end to hold the slide while the shutter is being drawn completes the apparatus.

When the dark slide is just inserted in the repeating back the first third of the plate will be exposed. When pushed along to the mark the second third, and, at the farthest end, the final third will be uncovered. This will be found quite useful, and is intended to be used in conjunction with colour filters on the lens.

A form which carries the filters just in front of the plate can be made with very little more trouble. Make just as for the first form, but omit the velvet. Then make a carrier for the filters as follows:—The wood wanted will be one piece each, 8 in. by 6 in. by 3-16 in., 8 in. by 5½ in. by ¼ in., and 8 in. by 7 in. by ¼ in. Two pieces 8 in. by ½ in. by 3-16 in., and two pieces 8 in. by ¾ in. by ¼ in.

In the 7-in. pieces a half-plate opening is cut, in the other two the opening should be about ⅛ in. smaller all round. These three are glued together as follows:—The 6-in. piece, then the 5½ in. and then the 7 in., the first two so that the edges of the opening are level, the top piece so that a ¼-in. ledge is left all round for the screens to rest on. They should have a screw passed through at each corner. A shallow groove is cut right along the two narrow ends on each side about ⅜ in. wide, and narrow strips of velvet or plush glued in firmly to form light-traps. The strips of wood are glued along the edges of the wide piece as in the first model. This carrier is inserted in the groove in the repeating back and strips of wood fixed so that it will not come out. The screens are fixed in position in the carrier either by small metal clips or by strips of lantern binding glued along the edge.

To make sure that no stray light reaches the other portions of the plate while one is being exposed, fix a thin strip of wood along each side of the opening, so that they just touch

the face of the screens. A coat of dead black should be given to all inside parts of the carrier.

The best form of filters for the last model can very easily be made. Obtain tri-colour gelatine film from the plate manufacturers, size 4¼ in. by 2 in., and fix between two half-plate pieces of glass, either by simply binding with lantern-slide binding or with Canada balsam, but this last is not really required in so small a size.

Of course, a good woodworker would get the same result by different means, but, as set out, any man that can use a few ordinary tools will have no difficulty in getting a good result.

JOHN C. ARCH.

THE DISPLAY OF SCREEN-PLATE TRANSPARENCIES.

At the present time, doubtless for reasons of economy, most colour photographers working the screen-plate processes do so in the smaller sizes, such as 3½ × 2½ or ¼-plate. In course of time, as the collection grows, the worker finds it more or less of a problem how to display the transparencies to the best advantage.

One of the chief difficulties in showing a collection of colour transparencies to the best advantage is due to the fact that there is too much light in the ordinary domestic apartment to admit of the fullest impression being gathered of the brilliance and quality of the colours. Let the colour photographer block up a small window somewhere in the house temporarily while the sun is shining upon that side of it on a bright day, thus darkening the apartment. Then let the worker cut out a rectangle in the blocking medium the exact size of his colour photographs; and view the picture under these conditions. He will learn a number of useful things, and will most certainly find that a good colour transparency is a very beautiful thing indeed, and also he *may* gain an enhanced idea of the qualities of some of his own productions. Still, it is not necessary to have a darkened room in order to look at a collection of Autochromes. Apart from this factor of prime importance, the light behind the transparencies should be white, strong daylight being, of course, the ideal. When the light is yellow or weak, the best effects in the colour pictures will not be seen satisfactorily, while, upon a dull, winter afternoon, very little colour can be seen even in the best of transparencies.

Next to daylight, white artificial light may be employed with satisfactory results; both electric light and incandescent gas have advantages as regards uniformity, though with these all light, except that which comes through the pictures, should be minimised.

Much may be done to enhance the value of a good colour transparency if attention is paid to the mounting of the pictures, and the photographer should be careful to mount the picture so that its back is shielded from direct front light. For transparencies of half-plate size and upwards, it is a good plan to have each one in an open frame of fairly deep moulding to isolate the picture from its surroundings and cut off light not actually needed to penetrate it. This frame is supported upon struts at an angle of about 45 deg., and at the back of it is laid horizontally a white reflecting card or, better still, a mirror, to reflect the light up into the colour picture. A specimen of this may, I think, be seen holding a portrait Autochrome in the museum at the house of the Royal Photographic Society. If the front of the frame can be fitted with a simple form of hood, which need only be of stout card covered with American cloth, through which the transparency is examined, and the whole stood upon a table near a well-lighted window, no trouble will be experienced in getting a satisfactory view of the picture. This costs but little, and may be so made that the colour transparencies may be easily changed. If the transparencies are only of small size, such as 3½ × 2½ inches, the frame may be larger, and a number inserted between two pieces of glass. In this latter case care must be taken to stop all light coming between the transparencies. If they are carefully arranged in, say, sets of a dozen or eighteen a surprisingly attractive and brilliant effect will be produced, and, to my mind, there is no better way of displaying a collection of screen-plate colour-transparencies. If the photographer does not wish to go to the expense and trouble of fixing the two struts of a hood and reflecter, as above suggested, the frames may be simply examined against the light in the usual way.

Another way of dealing with small colour transparencies is to mount each one between two larger pieces of glass, the unoccupied spaces upon the glass being filled in with cardboard, the whole bound up with "passe-partout" binding, and a black paper mark fitted to the front of the transparency. This will serve in isolating the picture from its surroundings and assist in viewing.

Autochromes are often mounted in the folding mirror cases issued by Lumière for this purpose; the colour transparency is placed at the top, and its image reflected into a mirror on the inside of the case. This method is entirely satisfactory: the picture is viewed without difficulty, and all surplus light is cut off by the sides of the case.

In conclusion, it may be remarked that at photographic exhibitions the colour work has not been shown under fair conditions in the past years, even the R.P.S. itself not being above reproach in this direction. I for one am glad to read that the Council have given this matter their attention, and have devised a better method of showing the exhibits in this section, an announcement which should encourage a larger entry.

ROBERT M. FANSTONE.

THE LATE HENRY HESS.—We see the announcement in an American journal of the death of Henry Hess, a mechanical engineer in the United States, who for some time was associated with Mr. F. E. Ives, in the Hess-Ives Co., formed to place certain of Mr. Ives' inventions on a commercial basis.

THE PRINCE'S TOUR IN COLOUR CINEMATOGRAPHY.—Incidents of the Indian tour of the Prince of Wales are being recorded by the Cinechrome process of colour cinematography, an additive two-colour method which has not yet been publicly exhibited. Five Cinechrome operators have accompanied the Prince on his tour.

LONDON'S COLOURED BUILDINGS.—Colour photographers who complain about the drabness of London's streets and buildings, and the unsuitableness of the same for screen-plate pictures, will be interested to to learn that Mr. Thos. E. Collcutt, the veteran Past President of the Royal Institute of British Architects, has organised a competition for young architects and students, who are to prepare designs for a business building facing on an ordinary London street, in which "colour" of a permanent nature is to be the dominant feature. £200 has been given by an anonymous donor to provide prizes.

THE HAMBURGER PROCESS OF COLOUR CINEMATOGRAPHY.

INVENTION in colour-photography continues to find its chief activity in the field of colour cinematography, where, however, the problem is of infinitely greater difficulty; the rewards, on the other hand, correspondingly great. It is pretty evident from the accounts which are published of inventions for motion pictures in colour that the commercial demand is for a film in colours which can be shown in any cinema projector in exactly the same manner as an ordinary monochrome film. This requisition again makes the most severe demands upon the ingenuity of the inventor and the skill of the manufacturer. As a means towards reducing the complexity of the problem, two-colour processes of cinematography have been in the forefront of late years, and undoubtedly there is a good deal to be said commercially for the adoption of this simpler form of the process, since the audiences in cinema theatres are not of a highly critical kind, and undoubtedly will be quite satisfied with pictures in colour, even though the colour rendering is not a faithful reproduction of the colours of Nature or of the costumes and scenery in a studio-produced film. The great thing is that the animated colour pictures should be pleasing in character, should have a wider range of colours than has been obtainable hitherto in two-colour processes, and particularly, should be readily producible on the industrial scale.

These considerations having long been in our mind, we were greatly interested in having the opportunity a few days ago of witnessing a laboratory and screen demonstration of a new method of colour cinematography—of colour-photography also—which has at length been worked out by Mr. Aron Hamburger, who, as many people no doubt know, has assiduously devoted himself to this problem for some years past. The process which we witnessed is a two-colour method in the sense that two films are exposed in the taking camera, one representing the red and yellow colour sensations, and the other the green and blue-violet colour sensations. The particular novelty of the new process does not concern the taking of the negatives, although certain improvements have been made in this part of the process as the result of Mr. Hamburger's previous experience and research in making colour separation negatives at one exposure for composite three-colour printing. The new feature of the method lies in the production of the ready-to-show cinema colour film. A new form of simultaneous selective dyeing and mordanting of four colours on to the film at one operation has been designed and unquestionably appears to be of such simplicity in operation that the making of films on the industrial scale should be an easy matter.

One method of working the process is as follows:—Printing is done on a double-coated positive film, images from one colour-sensation negative being simultaneously printed on one side in register and corresponding with those of the series from the other negative on the other side of the film. This double monochrome film, having been developed, fixed and washed in the ordinary course, is then treated in a special machine by which the two sides are simultaneously coated, one with a mixture of red and yellow dyes, and the other with a mixture of blue-violet and green dyes.

The crux of the process lies in the discovery of a definite chemical reaction, which takes place between certain organic dyes and silver photographic images, in the presence of certain reagents. This reaction renders the silver image selective of the colours with which such images are created, in direct relation to their colour value. The dyes which have been found to respond to this reaction are extremely few in number, but practically the whole spectrum has been covered by the colours which have now been standardised for the process.

The film having received this duplex dyeing (or rather coating, since at this stage it is not chemically dyed), on each side, it is then treated as a whole in a bath which simultaneously converts the silver image into a dye-receptive compound, and mordants the dyes to form staple dye images. At this stage of the process the film scarcely shows the pictures of which it consists, since these are masked by the excess of dye which is used. It is in the next stage, that of washing, that the special feature of the process becomes evident. It is found that in the case of the series of pictures which have received the mixture of red and yellow dyes, the result of washing is to obtain a gradual gradation from red to yellow in the colour of the dye image in correspondence with the density of the original silver image; that is to say, the shadows in the pictures are dark red, due to fixation chiefly of the red dye, whilst the high-lights are yellow in consequence of a like fixation in these parts of the yellow dye, the dyes are completely discharged from the non-silver portion of each image leaving unstained whites. Similarly, on the other side of the film, the process results in emphasis of the blue in the shadows and the green in the high-lights. The remainder of the process consists in the use of a mordanting bath for fixation of the colours and of a clearing bath for removal of the silver compound, thus leaving ultimately a pure and exceedingly transparent duplex, or, perhaps, one should say quadruplex, dye image.

We were interested in hearing the expression by two eminent dye chemists, with whom we witnessed the demonstration, of their very great interest in this phenomenon of selective dyeing during the chemical treatment of the silver image. Mr. Hamburger has his theory that the phenomenon is due to graduated saturation of the silver image by one dye, so that the other is limited in the degree of its action. We heard also the suggestion that the effect may be due to the different rates of diffusion of dyes of different molecular weight. However that may be, it was evident that the process allows of a considerably greater variety of colours being produced in the finished film taken from two negatives than is the case in other processes likewise based on the making of two negatives. We saw on the screen a considerable number of short lengths of film in which there were well rendered not only the hues of complexions, but also yellows, greens and blues. So far as the production of colour film is concerned it is pretty clear that the dyeing and subsequent operations may be carried out as readily and quickly as the processes of development, fixing and tinting which are in regular employment in the making of monochrome films.

The process also is applicable to the making of colour photographs, either prints or transparencies, since two negatives may be exposed in almost any ordinary camera, film to film, prints made from each and dyed with a mixture of dyes, mordanted, washed, etc. For either a print or a transparency assemblage in registration is thus reduced to the single operation of putting two films together for mounting either on paper or on a transparent support. We understand that the process has been covered by patent, the specification of which should be published before very long by the Patent Office.

DESENSITISING IN THE DEVELOPMENT OF AUTOCHROME PLATES.

THE advantages of the desensitising process in the development of Autochrome plates are the subject of strong recommendation by M. J. Carteron in a recent issue of "La Photo-Pratique." M. Carteron confines himself to the use of phenosafranine as a preliminary bath, which, he finds, is the only way in which the desensitiser can be employed with Autochrome plates. A suitable strength of bath is 1 part phenosafranine in 2,000 parts of water.

For developing a quarter-plate Autochrome about 3 ozs. of this desensitising solution is placed in a quarter-plate dish, and the Autochrome plate immersed in it in the dark. After the expiration of 1 minute, development may be done by bright yellow light or by the light of a candle placed about 5 or 6 ft. from the development dish, with or without the interposition of a pale yellow screen in front of it. Developing under these conditions the appearance of the image may be readily followed either by reflected or transmitted light.

The developers usually employed for Autochrome plates serve equally well when a desensitiser is employed. The following metol-hydroquinone is a very good one:—

Metol	3 gms.	25 grs.
Soda sulphite, anhydrous ...	75 gms.	1½ ozs.
Hydroquinone	8 gms.	70 grs.
Soda carbonate, cryst	60 gms.	1¼ ozs.
Potass bromide 10 per cent. solution	5 c.c.s.	40 minims.
Water, hot	1,000 c.c.s.	20 ozs.

The water should be boiled before use, and employed after it has cooled a little.

A developer of hydroquinone alone may be used, since the preliminary bathing of the plate in the desensitiser greatly accelerates the developing power of the hydroquinone, particularly if the bath contains potass bromide. It then yields results which do not

suffer from excessive contrast; in fact, the results are closely similar to those obtained with metol-hydroquinone.

Fog is conspicuously absent, and development can be continued as long as required, working either on the factorial or time system, or, according to the method by which the progress of development is judged, by the change of the image from a negative to a positive.

As soon as development is finished it is seen that the Autochrome film retains a certain quantity of the phenosafranine, which gives it a yellowish tint. This colouration cannot, of course, be allowed to remain in an Autochrome transparency, but it disappears in the reversing bath of acid permanganate. The phenosafranine has no injurious action whatever on the rendering of the colours by an Autochrome plate.

After rinsing the plate for 30 seconds in clean water it is placed in the customary reversing bath made up of potass permanganate and sulphuric acid, the reversing action being followed in full light.

M. Carteron dwells particularly upon the advantage of the desensitising method in the treatment of Autochromes. Apart from the elimination of fog, there is, he finds, an advantage in the satisfactory use of plates which have exceeded the time limit allotted to them by the makers. Moreover, he is inclined to think that stronger results are obtained when the plate is desensitised, and that thus better results are obtained when exposure has been somewhat cut down.

MAKING PAGET COLOUR NEGATIVES IN A SMALL ROLL-FILM CAMERA.

THERE must be many amateur photographers who possess only a small folding pocket camera of the roll-film pattern who would like to make an essay with the Paget colour process, but who do not wish to go to the expense of a plate camera for this purpose. The following notes and illustrations will show how very simply a watch pocket camera of the 2¼ square pattern was adapted for the Paget process with success. The plan, with necessary variations, may be employed with any roll-film camera fitted with a detachable back, and of a size for which the taking screens and panchromatic negative plates may be obtained.

As will be seen from fig. 1, which shows the camera with the back removed and the plates and springs in position, the spool chambers are filled temporarily with pieces of wood, cut as shown in the sectional sketch fig. 2. The projection A comes upwards

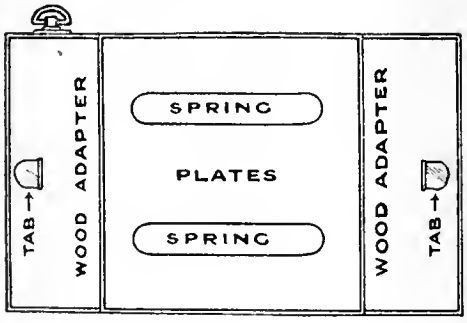


Fig. 1.

Fig. 2.

and extends *inwards* to form a rebate, into which the taking screen and panchromatic negative plate may be inserted without the latter slipping. Two of these adapters are needed; they should be tightly fitted, and a couple of tabs of thin leather tacked to the outer edges in order to allow ease of removal. One of the adapters may have to be slotted, in order to allow the admission of the winding key of the camera.

The only other necessities are two springs to press the plates close together, with a view to ensuring perfect contact between the two. For this purpose an old clock spring of about three-quarters of an inch in width, and not too strong, which can be bought for a few pence from any jobbing clock repairer, serves well. For the 2½-square plates, two pieces, each about two inches long, are bent into a half-moon shape, with the edges just turned upwards in order to avoid scratching the plates. For larger sizes, longer springs must be used. A piece of thin black card is also needed, slightly larger than the plates and screens.

To load the camera, the yellow film filter should be inserted between the components of the lens, and the two wooden adapters inserted in the empty spool chambers. The camera is then taken into the dark room, the taking screen placed in position *film up*, the panchromatic negative plate laid upon this, *film down*, and then on the glass side of the plate is laid the piece of black card. This protects the plate from any chance of fog from the ruby window at the back of the camera. Upon this card the two springs are laid, and the back of the camera put on and clamped in the usual way. Care should be taken that, while the springs are strong enough to ensure contact between the two plates, they do not force the back of the camera open. Though the average film user might expect difficulty in loading the camera as suggested, this is not the case if the green safe light issued by the Paget Company is carefully employed, but at a safe distance.

Though simple, this method of making Paget colour negatives will be found satisfactory in use; in fact, better results may be obtained than is often possible with the single metal slides so popular to-day. The only disadvantage lies in the fact that only one negative can be made at a time, but, at any rate, the device allows colour photography to be practised in or near the home.—R. M. F.

A COMING COLOUR PROCESS.—At the Royal Photographic Society recently the president, Mr. W. L. F. Wastell, in the course of some remarks on a triple assemblage method of making colour prints, expressed the opinion that the process which would render colour photography generally popular would be on entirely different lines from those in which three colour components were superimposed. He added that he had good reason for saying (although he was debarred from making a more definite statement) that such a process would make its appearance before very long.

SCREEN-PLATE RENDERING OF THE SEA.—At a recent meeting of the South Suburban Photographic Society the questions of the precise colour of sea-water and the more or less satisfactory screen-plate renderings of scenes at or by the sea were discussed, a much-travelled member making some remarks of particular interest to colour workers. The intense blueness of the sea, depicted in Autochrome pictures made on the Riviera, was commented upon, no English-made picture of the sea showing such rich blueness. The sea is usually described by descriptive writers, and pictured by artists, as being blue, but as everybody who has seen the sea knows this is not always the case. The natural colour of water in bulk, it was stated, may be said to be blue, but the blueness is always modified by particles of matter held in solution and by the colour of the ocean bed. A good blue sea, it was pointed out, was impossible on the muddy bed at Southend, one was far more likely to find blueness on shores washed by the Atlantic, or at Bournemouth, where the water was deep. The open and deep sea is usually blue enough for Autochrome workers, but shallow seas are of a greenish tinge, with a tendency to muddiness. The sky and atmosphere also play their part in making the water appear of varying colours. On a summer's day, for example, the sea may have the appearance of molten silver, while on a dull, cloudy day the water will appear to be lead-coloured, because of the reflections from the sky. It was, one speaker said, the intense blueness of the sky above the Mediterranean that gave blueness to the water, and it was useless to expect such blueness on our own coasts. Screen-plate pictures taken looking seaward from Monte Carlo had been taken to the shore a short time after taking and finishing, and the blueness of the Autochrome had been compared with the blueness of the water; the colour was found to be faithfully rendered, but on bringing the pictures to England the blueness was questioned and hand-colouring suspected. The blueness appeared to be more intense, or "Recketty," when viewed in England than when viewed at Monte Carlo. Authorities (non-photographic) appear not to be in agreement concerning the real cause of the ocean's blueness, some maintaining that the blueness depends upon the amount of salt contained in the water, it being pointed out that the Mediterranean and the Gulf Stream are both very salt, and that the former is a deep azure, while the latter a decided indigo blue. Another speaker said that this condition could not relied upon, for the bluest sea he had ever seen was the Sea of Galilee, the water of which is fresh and drinkable and not salt, while the Dead Sea—the saltest sea on earth—was of a very disappointing blueness, much below the Mediterranean in richness of colour and very much behind the blueness of Galilee.

EXTRA-SENSITISING OF AUTOCHROME PLATES.

[Considerable interest has been aroused in France by the publication in the "Bulletin" of the French Photographic Society of a note by M. F. Monpillard, deposited with the Society in a sealed packet in January, 1913, describing a method of obtaining greatly increased sensitiveness, up to thirty times, of Autochrome plates. M. Monpillard's communication has been followed by a paper on the practical employment of the method by M. L. Gimpel, who was a collaborator, in the use of the extra-sensitised plates. The following is a translation of the two communications.]

M. MONPILLARD'S NOTE OF 1913.

The first experiments relating to the method described in the present note, which has been written for purposes of claiming priority, date from November, 1911. In view of the fact that most of the formulæ for solutions used in orthochromatising or panchromatising plates contain ammonia, I formed a theory that the effect of this ammonia was to dissolve a minute proportion of the silver haloid in an emulsion, and thus to facilitate the combination of the silver haloid with the colour sensitiser so as to give sensitiveness to certain rays of the spectrum.

This hypothesis of a combination between the silver and the dye is quite in accordance with observed facts. An aqueous solution of eosine can be precipitated by a soluble silver salt, the resulting coloured precipitate being soluble in ammonia.

Starting from this hypothesis it occurred to me that the general and colour sensitiveness of a photographic preparation could be augmented by means of an orthochromatising bath containing sensitising dyes combined with a suitable silver salt. In the first instance I turned to combinations of silver with chlorine, bromine and iodine, and my first experiments were made with silver chloride, chosen on account of its special solubility in ammonia.

The first experiment on these lines showed me that a very considerable increase in the general sensitiveness is produced by the presence of a very minute quantity of silver chloride in the colour-sensitising bath. At this time (November, 1912) M. Simmen confirmed this result experimentally.

By a series of systematic experiments I then determined, for the special case of the extra-sensitising of Autochrome plates, the best proportion of silver chloride for addition to the colour-sensitising dyes in order to obtain the maximum effect without risk of fog. Under these conditions it was found that the sensitiveness attained by an Autochrome plate is thirty times that which it possessed before treatment. On the other hand, experiments showed that this sensitiveness is preserved for at least thirty-two hours, and that no fog is produced even when this period elapses between the treatment of the plate and its development after exposure. At the same time absence of fog is conditional upon the quickness with which the plate is freed from the sensitising solution and is subsequently dried.

Experiments were successfully made with citrate and with acetate of soda, also with silver potassium cyanide, in all cases in ammonia solution. The last-named double salt does not permit of the sensitiveness being increased so greatly as with silver chloride. Silver citrate possesses little advantage, and silver acetate gives fog. In an experiment made on January 12, 1913, the use of colloidal silver solution instead of silver chloride appeared to give interesting results.

On the whole, while silver bromide and silver iodide in the presence of certain colour sensitisers conferred greater sensitiveness to certain rays than does silver chloride, the insolubility of silver bromide in ammonia and the very slight solubility of silver iodide in the same solution showed me that it is not practicable to employ these compounds in place of silver chloride or to use them in conjunction with silver chloride in colour-sensitising baths. It occurred to me, however, to add a soluble bromide or iodide to the ammonia solution of silver chloride in the hope that a reaction would be produced in the sensitive film and that bromide and iodide of silver would thus be combined with the colour-sensitising dyes. Nevertheless, experiments showed that the addition of any soluble bromide, producing a precipitate in presence of silver chloride, was useless. On the other hand, addition of solutions of ammonium iodide, zinc iodide, or cadmium iodide, is possible within limits. The first experiments showed that a considerable increase of sensitiveness can be produced in the gelatino-bromide emulsion by this means.

In concluding this note I will add that my laboratory tests having interested our member, M. L. Gimpel, the latter has rendered me the help of his wide experience in the practical use of the results which have been obtained, and I have to thank him for the very valuable assistance which he has given, and continues to give.

F. Monpillard.

P.S. Applying this method to the treatment of plates for ordinary monochrome photography M. Gimpel has been able to make night photographs with relatively very short exposures under the ordinary lighting used in Paris.

INSTANTANEOUS EXPOSURES ON AUTOCHROME PLATES.

[The following is the paper by M. L. Gimpel to which reference has already been made. We are indebted to the French Photographic Society for permission to make the translation from the Society's "Bulletin."]

I must first express my deep regret that M. Monpillard, owing to his distance from Paris, is not able himself to make this communication with the clearness and ability which the Society has so frequently had the opportunity to appreciate.

As is well known, the Autochrome plate has a sensitiveness which is from 1-50th to 1-60th that of an ordinary rapid plate, such as the Lumière "Blue Label," employed in monochrome photography. This low degree of sensitiveness arises largely from the absorption of light by the coloured starch grain and by the compensating light-filter, and renders it impracticable to give instantaneous exposures except under the two following exceptional conditions:—

(1) Marine subjects, which, owing to the great actinic strength of the light, can be taken at speeds ranging from 1-5th to 1-10th of a second with a lens working at about *f*/4.

(2) Exposures from a balloon. These may be taken at about the same speed, provided that the angular movement of the balloon is very small. I made the first of such exposures in the year 1898 at an elevation of several hundred metres above St. Leu-Taverny and Falmondois.

It was natural that the idea should occur to certain workers of increasing the sensitiveness of Autochrome plates sufficiently to permit of instantaneous exposures. One of our members, M. Simmen, showed for the first time at a meeting of the Scientific section on June 14, 1910, and afterwards at the general meeting on July 8 of the same year the result of his work in this direction. By combining the colour-sensitising dyes, pinachrome, pinaverdol and pinacyanol in weak alcoholic solution without addition of ammonia, M. Simmen devised a hyper-sensitising bath in which, by immersion for a few minutes, followed by rapid drying, the plate was rendered four or five times as sensitive.

This increase of sensitiveness, specially for the less refrangible rays of the spectrum required the modification of the light-filter which M. Simmen prepared at first solely with æsculine; that is to say, a colourless filter absorbing only the ultra-violet rays. The plates could be kept before development for about three weeks.

M. Simmen's communication was accompanied by the projection of a number of transparencies which created much interest, although the colours of some scenes were not rendered quite satisfactorily. Afterwards, when the process had been worked out, M. Monpillard showed us that hyper-sensitising favours the reproduction of some colours; violets and purples, which the Autochrome plate in the ordinary way does not always reproduce correctly, are rendered with great fidelity on the hyper-sensitised plates.

At a meeting of the Society on November 18, 1910, M. Emile Vallot, well known for his work in three-colour photography, presented a hyper-sensitised Autochrome taken at Luna Park, Neuilly, showing perfectly the life and colour of this thoroughfare. M. Vallot explained that he had simply used the Simmen process, with very slight modification of the proportion of the dyes and with introduction of a little yellow into the light-filter.

The results obtained by M. Vallot prompted me to make some experiments, and my first hyper-sensitised Autochromes were made on December 28, 1910, with plates which M. Simmen had kindly sensitised for me. M. Vallot also very kindly gave me all the details of his method of working, and laid particular stress on the use of a whirler for removing surplus sensitising solution from the plates in order to dry them as rapidly as possible. M. Vallot stated that his sensitising formula was somewhat inferior to that of M. Simmen, inasmuch as the plates did not keep quite so long, but experience showed me that by taking suitable means for rapid drying they could be kept for more than a month.

Another experimenter, M. Thovert, used a single sensitising dye, namely, pinachrome, the employment of which allowed of the use of a light-filter which could be purchased in the ordinary way, namely, that made by MM. Lumière for the reproduction of Autochromes by magnesium light. Other contributions to the practice of hyper-sensitising were also made by M. Palocsay and M. Jové; and on March 15, 1912, M. Adrien showed a very simple apparatus by which any amateur could easily hyper-sensitise his plates. This device, coupled with the sale of the sensitising solution by MM. Poulenc, ready for use and standardised by M. Monpillard, should have extended the use of this method among Autochrome workers, but, unfortunately, little interest is taken in it.

Towards the end of 1911, or beginning of 1912, M. Monpillard, knowing that I was interested in instantaneous colour-photography, particularly in my work for "L'Illustration," told me that he was experimenting with a new process of hyper-sensitising, and that the first laboratory tests had given results, as regards increased sensitiveness, which he had never hoped for; further measurements showed that the sensitiveness was increased thirty times. I anxiously awaited information concerning the method, but my first subsequent meeting with M. Monpillard was a great disappointment. M. Monpillard told me that his idea had no practical interest, since the plates had to be used at once, their preservation in working condition being a matter of hours. While admitting this drawback, I pointed out to M. Monpillard that there were many occasions on which the process could be used. However, M. Monpillard held to his view, and we did not discuss the process until November, 1912. M. Monpillard then said that he wished me to study the practical use of his process, which latter he had described in a memorandum deposited as a sealed packet at the French Photographic Society on January 17, 1913.

In the course of my experiments, ranging from November, 1912, to July, 1919, we tried the compensating light-filters most suitable for correct rendering of colours in daylight and by incandescent and arc electric lamps, since these latter were used in the theatres. M. Monpillard worked out twenty-six different light-filters which I tried in the workroom, out of doors, and at the theatres. We used 320 plates in these tests and in our experiments, made for the purpose of improving the keeping properties of these ultra-sensitised plates. I use the word "ultra-sensitised" to distinguish the process from that (hyper-sensitising) in which a lesser increase in sensitiveness was produced. M. Monpillard, being unable to continue the work which we had undertaken for the purpose of perfecting the process, decided at length to publish the contents of his sealed memorandum, as was done at the meeting of the Society on March 24 last. He did so with the hope that other experimenters would succeed where we had failed. When the note was read some dissatisfaction was expressed that it did not contain the sensitising formula which was used. I can now remedy that deficiency. The difference between ultra-sensitising and hyper-sensitising consists simply in the addition, at the time of use, of a small quantity of silver chloride dissolved in ammonia to the mixture of the sensitising dyes. The following are the stock solutions of the dyes:—

A.	Pinaverdol	1 gm.
	Alcohol, 90 deg.	1,000 c.c.s
B.	Pinachrome	0.05 gm.
	Alcohol, 90 deg.	1,000 c.c.s.
C.	Pinacyanol	0.05 gm.
	Alcohol, 90 deg.	1,000 c.c.s.

Solution D.

Stock solution A	100 c.c.s.
Stock solution B	100 c.c.s.
Stock solution C	47 c.c.s.

According to theory, 56.4 c.c.s. of the C solution should be required.

It must be understood that the latter figures are approximate. Before the war two different makes of sensitising dyes showed variations which required the composition of the mixed sensitising solution to be adjusted. Since the war the variations are greater, since dyes are not manufactured with such care and also because there are differences between those sold in Germany and those which are exported.

E. Concentrated Sensitising Solution.

Solution D	400 c.c.s.
Alcohol, 90 deg.	600 c.c.s

F.—Silver Chloride Solution.

Water, distilled	92 c.c.s
Ammonia, 22 deg.	8 c.c.s.
Silver chloride	0.2 gm.

G. Working Sensitising Solution.

Solution E	10 c.c.s
Solution F	10 c.c.s.
Alcohol, 22.5 deg.	80 c.c.s

As regards working methods, it is most essential to provide the means for drying the plate with the greatest possible speed. I think M. Vallot was the first to recommend a whirler for drying. There are, as you know, several patterns. I do not recommend the ordinary dark-room whirler, actuated by an endless screw, since the wear on the teeth is very rapid. The band type is certainly better, but on the whole my preference is for the water-motor pattern, which is rotated at the rate of 1,500 revolutions per minute with small consumption of water.

M. Vallot uses a grooved tank for the sensitising bath, and provides it with a capillary outlet, so that the solution drains away very slowly and completely, the plates being perfectly free from adhering liquid when they are removed. On no account must a metal dish or tank of any description be used for a sensitising solution containing the silver chloride. Glass or glazed earthenware must be employed.

For drying, an electric fan, delivering ample quantities of air into the grooved box in which the plates are arranged, is a necessity. M. Monpillard has described a fan suitable for this purpose ("Bull. Soc. Fr. Phot.," June, 1914, p. 184).

As regards dark-room illumination, in ordinary Autochrome work I use a lamp containing a carbon filament bulb of 5 c.p., provided with one yellow and two green Virida papers. For ultra-sensitising, I fold my Virida papers round a sheet of cathedral green glass and arrange the lamp so as to carry on the operations in shadow.

Sensitising should be done at a low temperature. In summer I make up a cooling mixture of ammonium nitrate and water, standing the glass dish containing the sensitising solution in this mixture. Having carefully dusted the first Autochrome plate, it is immersed in the sensitising bath and the stop watch started. At the end of three minutes the plate is quickly replaced by a second, and the first plate deftly placed upon the platform of the water whirler. After about a minute the water is stopped, and the surface-dried plate placed in the electric drying box. By working in this way no time is lost. If a box of four plates is being sensitised, by the time the fourth is being put into the drying cupboard the first will be ready for insertion in the plate-holder. This means that the first will have occupied about ten minutes in preparation, but it is practically certain that it will have been dry at the end of three or four minutes.

I do not recommend strengthening of the sensitising bath, as some workers have suggested. I prefer to use 100 c.c.s. for sensitising six 9 by 12 cm. plates and then to throw it away.

Exposures have been made with the *f*/4 Lœwe-Berthiot anastigmat fitted with the J. H. light-filter prepared by M. Monpillard for plates either hyper- or ultra-sensitised. While I am not particularly fond of the focal-plane shutter, I admit that for our special purpose of obtaining the greatest action of light its high efficiency is an advantage.

Development is important. M. Adrien has shown us some remarkable Autochromes made on hyper-sensitised plates and developed with pyro. But they were not instantaneous exposures, and pyro is the most unsuitable developer for Autochrome plates which have not been fully exposed. Some recent experiments made by Le Comte de Dalmas have shown that, as compared with pyro, one-third the exposure may be given if the plates are developed with metoquinone. I, therefore, use this developer in double strength, *i.e.*, 40 parts per 100, instead of 20 parts per 100, as recommended by M. Vallot.

Development should be done with as little delay as possible, since the ultra-sensitised plates keep for a very short time, and, moreover, this time varies considerably. The longest period which I have allowed to elapse, whilst still obtaining a satisfactory result, was 13½ hours, but it is well to develop, at any rate, within twelve to twenty-four hours of the plates being sensitised. I have tried many means for prolonging the preservation of the ultra-sensitised plates, such as keeping them under mercury, varnishing the film, immersion in carbonic acid or nitrogen, but all without result.

M. Monpillard and I made some experiments on the advantage of backing the ultra-sensitised plate with a white instead of a black card, as recommended by M. L. Lumière in 1910. Workroom tests on ordinary Autochromes showed that exposure could be reduced to about two-thirds by this means, but when we tried this method on the ultra-sensitised plates it failed completely. By courtesy of M. Lucien Guitry we made a series of exposures from a good place in the theatre on scenes in the play "Kismet," the ultra-sensitised plates being backed with white cards which had been kept in the dark for several days previously. On development not a trace of image was obtained on any of the plates. On the next day a new series of exposures were made on plates backed with black cards, with complete success. Shortly afterwards some tests were made by backing the plates with silvered copper plates, as used in the Daguerreotype process, but no difference could be found between these results and those made under the same conditions, except that the plates were backed with black cards. I mention these contradictory experiences without being able to explain them. Possibly the effect of the white card is simply to produce an initial change in the sensitive film, in the case of the ultra-sensitised plate this change perhaps proceeds altogether too far.

Here I should mention also a phenomenon, the cause of which we have been unable to ascertain. Some of our Autochromes have shown pinkish mottling of greater or less depth. In some cases this defect, which is encountered also with hyper-sensitised plates, shows over areas which have soft segmented edges, whilst in others the markings are well defined and resemble the patches produced by the use of developer in quantity insufficient to cover the plate.

Some of our results have been obtained from aeroplanes. By permission of M. Maurice Farman I made twenty-two flights, but from causes which I could never discover failed to obtain a single good Autochrome on the ultra-sensitised plates. I have one passable result to show you, made at about 200 metres in November, 1916, with an exposure of 1/50th of a second. The only satisfactory results were obtained by the hyper-sensitising process. With the help of the skill of the airman, who drove his machine against the wind at reduced engine speed, and with luck in dodging the roll of the machine at the moment of exposure, I made the first two Autochromes obtained from aeroplanes in May, 1917, with an exposure of 1/15th of a second at *f*/4.

L. Gimpel.

GARDEN PHOTOGRAPHY BY THE SCREEN-PLATE PROCESS.

If there is one branch of photography more than another in which the screen plate colour processes may be employed with advantage it is in the portrayal of garden scenes. This is a possibly remunerative field for the progressive professional photographer. Colour is the very essence of the delight of the garden, and without it, no matter how highly technical the skill of the photographer, even the best that a monochrome photograph can attain to will fail to satisfy the ideals of the owner or designer of a beautiful flower garden. This is the crux of the whole matter. The garden lover wants photographs as records of what he has accomplished, and which will last long after the glory of the original has departed. The field is a wide one for professional work. Certain seedsmen have adopted the idea, presumably using the three-colour process, though so far the results, from the point of view of truth and general photographic quality, leave much to be desired, particularly in the case of garden scenes, which are to a marked degree inferior to studies of individual flowers, though, of course, something may have been lost of the beauties of the original picture in the reproduction.

In order to be successful, the photographer must keep in mind the requirements of the owner of the garden, even if this entails the sacrifice of his own pictorial ideals to some degree. The forms and characteristics of the occupants of the herbaceous border correctly rendered will certainly be far more pleasing to the customer than a more artistic rendering of masses of colour. The foundation of success in faithful colour rendering lies in the greatest exactitude in exposure. If the subject is an important one, and the owner of the garden is prepared to go to the extra expense, it is a good plan to make a test exposure, as follows:—The meter test of the light is carefully taken, and the exposure worked out, we will assume, at 1 second. A colour plate is exposed in steps of, say, ½, ¾, 1, 1½ seconds respectively, pushing the shutter of the slide in after each one, in the same way that an exposure test is made when enlarging upon bromide paper. The plate is developed and quickly finished. Upon examination, the worker will be able to judge of the length of exposure to give to ensure the most satisfactory result. This is an essential experiment for any colour photographer who is wishing to get the finest possible results. The experiment suggested above will ensure much more faithful colour translations.

In regard to the choice of subject, the photographer is, as a general rule, in the hands of others, although he can do a good deal as regards choice of view point and lighting to bring about the most satisfactory results. He will do well to avoid, as far as possible, stunt lightings and freak effects. Figures may often be employed in assisting the composition of garden pictures in colours, especially feminine ones wearing bright or distinctive clothing. They may be suitably posed, strolling along walks or in the rose garden, and, if kept properly subordinate to the rest of the composition, have a decidedly helpful effect.

The choice of lighting should also receive careful consideration. Bright sunshine is almost essential in order to ensure that the colours are fully emphasised on the plate. The sun should not be directly overhead, the best results being generally obtained when the sun is low, early morning or late evening, in my experience, being productive of the best results. I need hardly say that there should be no wind, for nothing detracts so much from the beauty of an otherwise good colour transparency than blurred images, due to movement. If the work must be done during windy weather—and the fleeting nature of some of the subjects often demands that it is a case of "now or never"—still moments should be carefully watched for and the shutter closed directly movement begins.

In regard to equipment, little need be said. One point, however, may be mentioned. It is customary in this class of work to recommend a lens of fairly long focus. Whatever may be the advantages in this connection, there are certain disadvantages, and my own preference is for an instrument of fairly short focus, for the simple reason that depth of field may be obtained without too much stopping down. Even under the most favourable conditions the exposures are long enough, and a lens that will give a sharp image over many planes at an aperture of not less than $f/6.8$ is a decided advantage. ROBERT M. FANSTONE.

THE UVACHROME PROCESS.

SOME particulars of the process which has attracted a certain amount of curiosity on the Continent are given in the Festnummer of "Photographische Korrespondenz" by its inventor, Dr. A. Traube, of Munich. The process is one of dye-toning, in regard to which Dr. Traube refers to his patent of 1907, in which silver iodide, obtained by bleaching the silver image with iodine, was the mordanting substance. Apparently he claims to have been the first to have employed copper ferrocyanide in place of silver iodide as a dye mordant. He dwells upon the variations in the composition of the bleach of copper sulphate and potass. ferrocyanide, which may be made for the purpose of securing any degree of transparency or opacity in the dye-toned images. Moreover, the dyed copper ferrocyanide image is susceptible of being intensified or reduced within considerable limits. These properties of copper ferrocyanide are the base of the process.

In practice, a set of three negatives is made on Uvachrome film, viz., cinematograph film coated with a special emulsion. Soft transparencies are printed by contact, and treated in the copper bleaching solution. After washing for 5 or 10 minutes, they are dyed in colours complementary to those of the respective taking filters by means of special Uvachrome yellow, red and blue dyes, this operation requiring about 10 minutes. They are then treated for about half a minute in a clearing bath and washed. The clearing bath is chiefly of hypo, by which both the copper and silver ferrocyanides are dissolved out. After a further wash of 10 to 15 minutes the separate component images are dried, and are ready for assemblage.

Before mounting, however, the three films are brought one on another on a glass plate, and temporarily fastened together in register with clips. By this means the effect of the final result may be judged. If the negatives have been correctly exposed and printed, the colour rendering will be correct, but, as required, modifications can be made in the component dye images, any one of which may be reduced in depth by a bath of weak acetic acid or strengthened by a dip in the original dye solution. Dr. Traube does not say how the three transparencies of practically postage-stamp size are permanently superimposed in accurate register.

At present the process is adapted only for the making of three-colour transparencies, but it is hoped to apply it also to the making of paper prints. It is stated that thousands of the transparencies have been made, and that the percentage of throw-outs does not exceed 1 per cent. to 2 per cent.

DEVELOPER FOR AUTOCHROMES.—In "Photo-Era," E. K. Elmslie recommends the following developer:—Water, 5 ozs.; metol, 26½ grs.; hydroquinone, 3½ grs.; sodium sulphite (dry), ½ oz.; stronger ammonia, 1½ drs; potassium bromide, 15 grs. Use 2 drams of above plus 1 oz. of water. Develop 2½ minutes at 65 deg. F. Metoquinone can be made by mixing saturated solution of metol and hydroquinone in the ratio of their molecular weights, dissolving and precipitating with sodium sulphite. Consequently this ratio was used but precipitation was dispensed with altogether.

THE BLEACH-OUT PROCESS.—In a recent issue of "Photographische Korrespondenz" Professor R. Kögel has a short note on tests of a dye of the new phenanthrazoxonium group prepared by A. Kehrmann. He is inclined to think that these dyes will lead to a successful development of the bleach-out process, rather an optimistic view, considering the great labour which has been spent upon the process in the past without result. The particular dye was dissolved in alcohol and "sensilised" with thiosinamine. It was thereby rendered so sensitive that it bleached out in the dark. Anethol sensitising gave a mixture which was quickly bleached in diffused daylight, but remained unaltered in the dark.

COLOUR PRINTS BY DYE CONVERSION OF SCREEN-PLATE NEGATIVES.

[An ingenious process is described in a recent patent specification, No. 182,167, granted to M. Obergassner, for the conversion of a colour screen-plate transparency into a three-colour print. Mixtures of dyes are used for preparing each of the three series of colour elements in the three-colour mosaic filter screen. Exposure is made through this screen in the usual way and the emulsion developed (without reversal) and without allowing the developer to come in contact with the dye-coating of the screen. The latter is then sensitised with bichromate and printed through the negative image. It is then developed in warm water and the colours finally "rectified" by treatment in a bath of weak hydrochloric acid which acts upon the dye mixtures used for each colour element in the mosaic filter. The resulting film is then mounted upon an opaque white support.]

The invention consists in the employment of a colloidal three-colour screen containing partly dyes which, by treatment with acids or alkalies, or by neutralising, oxidising or reduction, are rendered colourless and partly substances which are originally colourless and become coloured by the same treatment, the effect being to convert the screen colours into the respective complementary colours. For instance, an alkaline mixture of erioglaucine and acid fuchsine is blue. By treatment with acid it turns red. Erioglaucine is bleached by acids, and acid fuchsine, which is rendered colourless by alkalies, turns red again by treatment with acids. The other colours can be formed and neutralised in a similar manner.

The following example will illustrate the process:—

A three-colour screen is made up by a mixture of about equal proportions of red, green and violet gelatine grains obtained by spraying warm coloured gelatine solutions. The solutions are prepared from an alkaline gelatine solution (about 1 part gelatine to 3 parts water).

For the red grains about 400 gms. of the alkaline solution are mixed with 2 gms. water-blue, 2 gms. fuchsine and 2 gms. naphthalene-yellow, each quantity dissolved in about 50 ccs. of water. The water-blue loses its colour in the alkaline gelatine, and the other ingredients produce a spectral red.

For the green grains similar quantities of gelatine solution, naphtha-flouranthene, spirit-green and naphthalene-yellow are mixed. The naphtha-fluoranthene turns bluish in the alkaline solution and produces with the other ingredients a spectral green.

The violet grains are obtained from 400 gms. gelatine solution mixed with about 40 gms. cold concentrated flavaniline-S solution which is rendered colourless in the alkaline gelatine and about 50 gms. methyl-violet. This mixture will produce grains of a spectral violet colour.

For the preparation of the screen a glass plate may be used to which in the first place a thin, waterproof collodion film is applied. This film is brushed over with a thin gelatine solution which is first allowed to dry and then moistened for adherence to the gelatine grains which are strewn over it. Non-adhering grains are shaken off, and the adhering ones are flattened out by pressure so as to fill up the entire collodion surface. Thereupon the two films are trimmed, and the colour screen thus obtained is removed from the plate. A panchromatic emulsion is applied to the back of the collodion film. The combined photographic film and screen thus obtained is placed between thin glass plates in a dark-slide and exposed in a camera through the screen in the usual manner. The negative is developed and fixed in a dish having in its bottom an aperture to the edges of which the films can be clamped so that no liquid is allowed to penetrate to the colour screen. After fixing, the colour screen is sensitised, *e.g.*, by means of potassium bichromate, which is effected in a similar dish and with the colour screen upwards, the screen being allowed to dry in the dark. When the screen is dry it is placed in a printing frame and printed through the negative, whereby those parts of the screen which are exposed to the light become insoluble. The soluble portion of the colour screen and also the photographic film are then dissolved in warm water and removed, whereupon the screen elements still remaining on the collodion film will form a transparent but wrongly coloured positive. The colours are rectified by immersion in dilute hydrochloric acid which turns the red into blue, the green into red, and the violet into yellow. Applied to a white background, the film will thereupon present a clear picture in natural colours, the darker patches being produced by the presence, at these places, of all the different colours in close combination.

In the rectification of the colours the fuchsine and the naphthalene-yellow of the red grains are rendered colourless, and the water-blue is restored to the original colour. In the green grains the spirit green and the naphthalene-yellow are rendered colourless and the naphtha-fluoranthene is turned red. In the violet grains the methyl-violet is rendered colourless and the flavaniline turned yellow.

A screen may be made up the colours in which can be rectified in a similar manner by immersion in an alkali.

If any of the resulting colours should not possess the required vigour, owing to a tendency of the dye substance to wash away in the water bath, the colloid used for producing the respective filter colour of subsequent screens can be mixed with a substance which in the further treatment of the screen image becomes insoluble and which either renders the existing final colour more vivid or serves as a foundation by which to bind the dye. For instance, the colloid may be mixed with dissolved chloride of barium. In the further treatment, dilute sulphuric acid can be used for precipitating therefrom barium sulphate which is able to bind the colour substance with sufficient tenacity.

In the process, however, it is not necessary to mix the primary dyes with other prepared but colourless dye compounds, as one or more dyes may be produced synthetically in the colloidal medium on the photographic plate or film from the components of the dyes or from the by-products of the coal tar industry, such components being added instead of the prepared dyes. In this manner the scope of the process is considerably widened. For instance, the primary dyes can be mixed with colourless salts of diazo and nitroso compounds, capable of being converted into the respective dyes by suitable treatment. Thus the final colour is produced by colourless components which are subsequently converted in the colour-rectifying bath into coloured dyes.

In the above example, for instance, the final yellow may be produced by means of two components, of which one may consist of a mono-sodium salt of dioxyquinoline and the other of a solution of para-toluidine-hydrochloride and sodium nitrite. These components are substituted for the flavaniline and will turn yellow after the treatment with dilute hydrochloric acid.

REMINISCENCES OF COMMERCIAL COLOUR CINEMATOGRAPHY—ITS POSSIBILITIES.

The appearance of the Prizma colour cinematography, and the comments by the "British Journal of Photography" on this process, has again brought before colour workers, as also the general public, the query as to the probability of commercial colour cinematography.

After ten years' research and practical personal working of processes that have given promise of such realisation; after seeing over a million dollars in hard cash melt away in the attempt to capture this elusive illusion, I feel that my years of unique experience should be at the service of the many searchers and students who have not had similar opportunities to investigate and analyse the possibilities and probabilities of commercial colour films.

Many processes have been tried by numerous workers, differing entirely from those on which I propose to treat, but as they never reached the public in even an approximately practical form, we can assume they suffered from some incurable disease, so I confine my dissection principally to the two apparently healthy specimens that have been offered as the real and only.

Before entering into the whys and wherefores of success and failure, we must decide exactly, but very reasonably, what the expression "commercial" applied to colour moving pictures must cover.

Leaving aside such delightful ideas as "absolute colour rendering," "true to Nature," and confining ourselves to the limitations of panchromatic films, photographic processes, and chemical dyes, let us accept as a definition "a process of animated photography in colour (the colours approximating to those of the best known examples of modern *still* colour work), workable under practically black and white conditions."

The two processes placed before the public on a large scale for commercial exploitation, are those of the late Kinemacolor and the early Prizma. I say "late" Kinemacolor with regret, for that process was the forerunner of what so many of us have been striving for, and I take my hat off to that energetic and always smiling personage, who through thick and thin nursed and cajoled that scientific baby of premature birth.

As most of those interested are aware, Kinemacolor was a two-colour process, employing panchromatic film, one lens, and recording a series of alternating "red and green" negative pictures.

The camera, of the ordinary type but more strongly built, mounted with a rotary two-colour screen of complementary colours, was supposed to run at 32 per second—but the seconds were short ones.

After development with panchromatic precautions, the negative, which consisted of a series of black and white colour value records, was placed in a printer, and a black and white positive printed therefrom. This was twice the length of the normal black and white, as two pictures were required to record one complete image.

The projector, of the common "beater" type, but of athletic build, provided with a synchronising colour shutter, was also supposed to run at 32 per second, but it was really driven at a dizzy rate, and it says much for its constitution that it survived as long as it did.

In spite of born showmanship that directed the destinies of Kinemacolor, and the sensational Durbar pictures that interested even Royalty, the process flickered out.

The chief reasons were: In recording negative:—

(a) The lack of exposure, except under unusual conditions.

(b) The irregularity of the panchromatic stock.

(c) The alternate exposure of the red and green images instead of simultaneous.

In printing positives:—

(d) The necessity of a "perfect" print to give satisfactory colouring.

(e) More than double the length of black and white.

In projection:—

(f) Special projector.

(g) Colour fringing.

(h) Fugitive colour screens.

(i) Frequency of "off colour."

(j) General "reddish" or "greenish" appearance of many of the pictures.

(k) Flicker, flicker, flicker.

(*a*) Lack of Exposure.—The camera shutter was about a half (180 degrees), the same as the average black and white camera; the speed was over 32 (more than double that of black and white). The exposure factor of the colour screens was from 10 to 14 times. Thus the camera man was forced to work under odds of at least 20 to 1, as compared with black and white.

This in practice meant working at full aperture (*f*/3.5) in sunlight, and in most countries only in the brightest time of the year. Perhaps to the uninitiated it does not appear a very great hardship, but it actually means a great limitation of subjects, and more than doubling or tripling the cost of

obtaining good negatives; under-exposed negatives, that in black and white would "get by," are useless in colour work.

(*b*) Irregularity of Panchromatic Stock.—In those days Kinemacolor had to manufacture their own stock by bathing black and white negative film in colour-sensitising solution, and it was no sinecure.

The negative was wound on 200 ft. pin frames. Usually three frames were run in each freshly-made-up dye bath. To compensate for usage of dye succeeding frames were left longer in the solution. The frames of dyed negative were then washed for a few minutes, the film wound on drying drums (in the dark), and dried.

Only those familiar with colour-sensitising dyes that are diluted to 1 in 50,000 to 1 in 100,000 can appreciate the cleanliness and freedom from foreign matters that must attend all operations, and it is indeed a wonder that Kinemacolor manufactured in quantities as good a product as they did.

(*c*) Alternate Exposure of Red and Green Images.—The method of obtaining the colour negative was on the principle of that patented by Lee and Turner (British, March, 1899). The latter, however, employed three-colour records. Smith went one better by using one less, and Smith and Urban took out a patent in 1906 for simply two alternating colours, roughly dividing the spectrum into two parts, using the complementary colour screens approximately red and green. The discovery of new dyes made possible for Kinemacolor what was impracticable in the days of Lee and Turner.

The camera employed was rather monumental, and, as the specialty of Kinemacolor was outdoor scenics, the work was hard on the camera man, reducing the output and increasing the cost of the negatives, I therefore had constructed a small Debrie model embodying the colour shutter. This model was adopted by the English and American Kinemacolor companies and gave satisfaction—especially to the camera-men.

(*d*) Perfect Positive Print.—It was very necessary to produce a clean, snappy print, developed exactly to the correct point. Any variation from this resulted in a totally different colour picture on the screen; unless a very skilled workman was employed the scrap heap again gathered up its spoils—complete harmony was necessary between the man at the printing machine and those who developed.

(*e*) Double Length.—As it took 2 ft. of film to show 1 ft. of action, cost of raw material was doubled, and lively action was necessary in the projection.

(*f*) Special Projector.—The high speed called for by the process necessitated a very robust projector, and it was provided with a revolving colour screen mounted on "ball" bearings, of which the maker was very proud. Although announced to run colour films or black and white, it would not handle the latter in a manner satisfactory to a showman with a conscience. At black and white speed there was *some* flicker. Therefore the man who wanted to show Kinemacolor had to install another machine in his already cramped booth, lay on more current, and engage an operator trained not to run away when this roaring film eater started up. A man with a weak heart had no chance.

Often 80 to 100 amperes of current, 40 to 50 pictures per second, and, when breaks occurred, if you were not very lively, you would be buried up to your chin in coiling celluloid. No wonder the Kinemacolor operators wore badges proudly; they deserved them.

(*g*) Colour Fringing was naturally the outcome of the method of recording the negative. If Kinemacolor had kept to scenics, for which it was adapted (who does not remember "The Lake of Como"?), this eyesore would never have been noticed, but familiarity breeds contempt, and when bold barons fought and fair maidens danced they were all wreathed in gaudy ribbons of red and green, which, however, in the maypole dance was very effective and always brought applause.

(*h*) Fugitive Colour Screens.—The colour screens on the projector were of ordinary coloured gelatine, and under a heavy amperage in a long programme became partially faded, causing a considerable variation in the colour rendering on the screen.

(*i*) Off-colour, or lack of synchronism between the colour values of the film and the colour shutter, was frequent, depending on the skill of the operator and the care with which the film was joined up. For unless a red image was always adjacent to a green image in a joint, the blue sky would suddenly become red, and green roses were far from rare. It was then necessary to stop the projector and "change colour," a very bad feature in showmanship.

(*j*) Reddish or Greenish Pictures.—Frequently a picture was spoiled by showing a pronounced tone, favouring either the red or green, caused by under-exposure, irregularity of panchro negative; or the blame attached to the camera-man for not carefully "balancing." The Kinemacolor camera-man had to be trained to his work, and one of his duties was to "balance" his colour shutter to the particular sensitiveness of his negative stock.

This consisted in photographing with his camera, and through the colour screens a white or grey surface, and developing the trial strip. If the colour screens and the colour sensitised negative were in accord, the red and green records showed an equal amount of density. Should the red image show a deeper intensity than the green, then the camera-man knew that the negative was "on the red," and he forthwith pasted a segment of black paper over his red colour screen to reduce the time exposure. Several trials were often necessary to find a good balance correctly; on this depended correct colour rendering.

To be absolutely correct this operation should be conducted under the same lighting conditions that would occur when the negative is exposed, for the composition of the sun's rays change with different localities, and in different hours of the day. It was naturally impossible for the camera-man to balance every roll of negative, therefore, many negatives were made that were not correctly balanced. To remedy this I invented a "Compensating" printer, provided with a sliding scale, which enabled one to add or subtract either colour value in predetermined quantities. This it successfully did, over quite a wide range, and many a negative was saved from the scrap-heap.

These "Compensating" printers were manufactured for me by Debrie, and were adopted by both the English and the American Kinemacolor companies.

(*k*) Flicker. I think it was this blemish that, more than any other, strangled Kinemacolor, for unless the pictures were of soft or dark tones, the speed of projection such that it made your hair stand on end, and the stage draped to kill reflections, there *was* an awful amount of flicker causing eye-strain, and more apparent was this to any one entering a show whilst it was running. Even the wonderful stagecraft of the Scala Theatre could not always conceal this; but why, oh why, did the girl with the red parasol always wander on the picture just as you were admiring the soft tones of a smiling landscape?

There was no remedy for this flicker, for when the bright red alternates with black, both having the same length of impressions, it is not a speed of 32 or 42, or even 52, that will smooth out a large area of these alterations.

When the unfortunate limitations of Kinemacolor were not strained, and only subjects taken that lent themselves to the conditions imposed, the results were truly wonderful, and I remember the late Professor Lippmann—one of the earliest workers in colour photography—coming round to the projection booth requesting to see with his own eyes that only two colours were actually employed. He did not believe it possible that such a combination of tones and shades could be obtained in this manner.

Having had unusual facilities for studying the disadvantages under which Kinemacolor worked, I set to work to try

and remedy as many of these as possible, and the new experiences I gained, if set forth, may save other workers both time and money.

My experiments were confined to sensitising, colour-screens, exposure, and improvements in projection apparatus, as these elements have immediate bearing on increased exposure, wider recording of colour values, colour pulsation or flicker, colour fringing, smoothness in working, and greater latitude in all chemical and mechanical operations.

CHARLES RALEIGH.

(*To be continued.*)

APPARATUS FOR THE DEMONSTRATION OF ADDITIVE COLOUR MIXTURE.

AN ingeniously-designed piece of apparatus for the demonstration of the effects of the mixture of coloured lights is described in the Festnummer of "Photographische Korrespondenz" by Professor John Herzberg, of Stockholm.

As illustrated in the diagram, the apparatus serves to show the formation of white light by a mixture of red, green, and blue-violet, and also of all the other colours of the spectrum. It consists of two circular transparent discs A and B, which can be rapidly rotated by means of the wheel D, through the cords SS. Each disc contains three sector-form light-filters R, G, V (red, green, and violet), consisting of stained gelatine mounted between mica sheets. In the case of A, the sectors are fully open, whilst in B the filters are of the shape shown in the figure. The discs have a diameter of about 3¼ inches, and thus can be projected on to the white surface of a projection screen by means of an ordinary optical lantern.

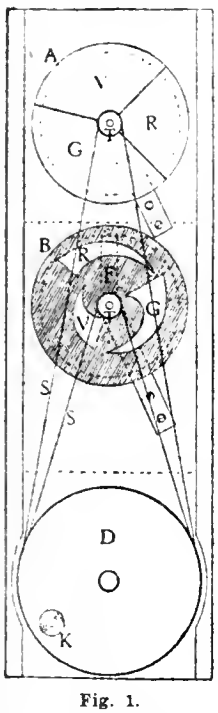

Fig. 1.

The filters are so chosen, and the angular measure of the sectors so adjusted, that perfectly white light is obtained on rotating the disc A.

Owing to the fact that blue and green dyes are never perfectly pure in colour, but more or less mixed with black, it is not possible to make a blue-violet, and still less so a green, filter which is sufficiently saturated and yet avoids degradation of the mixture. In order to compensate for the reduction which is the result of this mixture with black, the sectors are made of different angles. The red filter, which is the purest, is made 90 deg.; the green, 150 deg.; and the violet, 120 deg. If each sector is made of the same angle, *i.e.*, 120 deg., it is not possible to obtain a colourless mixture if it is also required that each sector filter shall be so saturated that it is completely extinguished by a filter of complementary colour without appreciably lessening the intensity of the other sectors. This latter requirement is of importance in the case of the apparatus for demonstration purposes, hence the design of the sectors as described.

For cutting out one sector in order to show the effect of mixture of the other two, the simplest plan is the use of a filter (absorbing the light to be cut out) on the projection lantern. Six selective filters were prepared for this purpose, and were so adjusted that each one absorbed two of the sector colours. If, for example, a yellow filter is used on the lantern, violet is absorbed and red and green transmitted. The originally violet sector then becomes completely black on the screen, and on rotating the disc, yellow results from the additive mixture of the red and green. Similarly, the green can be cut out with a purple filter and the red with a blue filter, the mixture of red and violet then giving purple, and that of green and violet, blue. The action of the selective filters used in three-colour photography can also be demonstrated; the orange-red filter transmits only the red; the green, only green; and the violet, only violet.

The disc B serves to show how the spectrum colours can be obtained by the mixture of any two colours. As shown in the figure, the sectors are partly covered, so that on rotating the disc the filters are gradually cut out from the centre to the circumference by the increase and decrease in the angle. In this way all colours of the spectrum from red to violet are produced. In the extreme red and extreme violet, as also in a very small green region, the particular filter colour is obtained without admixture. Hence in the regions near the middle or edges only parts of red or violet are respectively transmitted, according to the successive reduction of the angle of the sector, and thus a reduction of intensity of the outer colours is produced, causing them to merge gradually into darkness. The dull red corresponds with the extreme red of the spectrum; in proportion as green begins to enter into it, the colour passes gradually into orange and yellow. As the red falls off, the colour becomes yellowish green, passing to pure green as the red is eliminated, and giving blue-green and blue as the violet component comes increasingly into operation. Finally, as the green increases, the colour passes to indigo and violet. With the screen B in rotation there are thus seen on the projection surface concentric rings of colour, shading one into another, of all the colours of the spectrum. In order to obtain a more distinct representation of the spectrum as it is seen, for example, in the spectroscope, the apparatus is fitted with a sliding metal plate, provided with rectangular aperture F, as shown in fig. 1. When the aperture F is in the position shown in fig. 1, a band in the colours of the spectrum is produced by rotating the screen.

The filters for screens A and B contain the dyes mentioned below. The figures after the name of each dye are the number of grammes of dye per sq. metre of surface.

Violet filter: Passes violet and blue to about 498 $\mu\mu$; contains crystal violet, 1.5; toluidine blue, 1.25.

Green filter: Passes green, yellow-green, and yellow from about 498 $\mu\mu$ to 605 $\mu\mu$; contains naphthol green, 1.15; patent blue, 0.2; and tartrazine, 1.25.

Red filter: Passes orange and red to about 605 $\mu\mu$; contains Echtrot D, 10, and tartrazine, 15.

The six above-mentioned selected filters contain the following dyes:—

Yellow filter, absorbing the violet sector, tartrazine, 10.

Blue filter, absorbing the red sector, toluidine blue, 3.

Purple filter, absorbing the green sector, Rhodamine, 3, and Gentian violet, 0.15.

Orange-red filter: Absorbing green and violet sectors; Rhodamine, 3, and tartrazine, 10.

Green filter: Absorbing red and violet sectors; rapid filter yellow, 8, and toluidine blue. 3.

Violet filter: Absorbing the red and green sectors; Gentian violet, 3, and toluidine blue, 3.

The dyes used for these filters were those of Meister, Lucius & Brüning.

The chief difference between the colour mixture in the apparatus and in the methods of colour photography of Ives, Miethe, and others is that in the former the components follow in rapid succession, whilst in the latter they are presented simultaneously to the eye by projection or in the form of the various screen-plate transparencies.

SCREEN-PLATES WITH DIVISIBLE COLOUR ELEMENTS.—According to the specification of a patent No. 180,323, open to inspection but not yet accepted, S. Schapovaloff, 43, Waldheimstrasse, Berne, Switzerland, has devised a screen-plate process in which a support provided with a thin panchromatic sensitive coating carries between the coating and the support a screen of transparent elements. Each element is so coloured that a part of its colouring material is removable after exposure, for example by washing in water, by the action of light, or by chemical action, in order that the remainder may be weak enough to give the correct colour rendering when viewing the finished picture. The support may consist of glass, paper, or celluloid. The colour elements may consist of gelatine or rubber in the form of granules, flakes, or lines, and are preferably coloured twice with different colouring materials of the same shade, one permanent and the other temporary. A coloured transparent picture to be copied may be exposed through the support and screen. After developing and fixing, and the removal of the temporary colouring material, the support with its coating may be attached to white paper having an adherent surface. For transparencies, the permanent colouring material is of greater density than for non-transparencies.

A ONE-EXPOSURE THREE-COLOUR CAMERA

To those who look for a form of colour photography of greater simplicity than the sensitive screen-plate it may seem late in the day to design cameras and viewing apparatus such as greatly occupied the ingenuity of inventors thirty or more years ago. Nevertheless, a French experimenter, M. C. E. Bredon, has recently described in Patent No. 148,789 a photochromoscope and camera in which the three negatives are taken simultaneously. A single meniscus front element is made to serve for use in conjunction with three separate rear elements, prisms being employed to obtain three separate images. The apparatus is adapted for viewing the additive colour effects as well as for making the colour-sensation negatives.

The apparatus comprises three optical systems; one for each of three images which are projected on to a single sensitive plate and the invention resides in the combination of three lenses, an optical diaphragm having an aperture common to all three lenses and corresponding in size to the normal utilisable opening of each lens and two total double-reflection prisms, fixed against the inner face of the diaphragm, one on each side of the axis of the opening, so that each prism covers up a part of the diaphragm aperture and a space is left between the opposing edges of the prisms.

The luminous rays entering through the diaphragm aperture are divided by this arrangement of prisms into three bundles; the middle bundle passing, between the two prisms, direct to a central lens and the outer bundles being respectively translated to the two outer lenses by double total reflection in the prisms. It is a feature of the invention that the rays of light so reflected to the outer objectives, impinge on the latter exactly as the

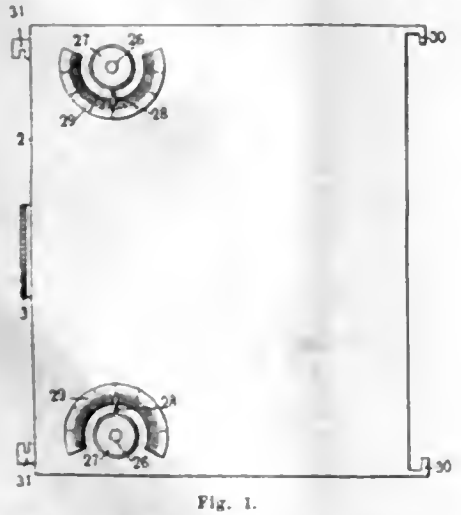

Fig. 1.

same rays would impinge on the central objective if they were permitted to reach it; hence the images produced on the two outer sections of the sensitive plate and the image produced on the middle section are absolutely identical in form.

The three bundles of rays which form these three images pass respectively through blue, green and red selecting screens before encountering the panchromatic plate.

Means are preferably provided for rendering the two prisms adjustable so as to permit regulation of the proportions of luminous rays passing through each selecting screen.

In the drawings, it will be seen, on reference to fig. 2, that

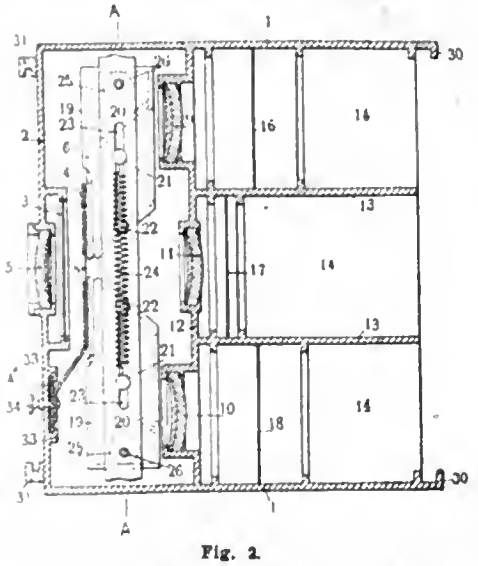

Fig. 2.

the body 1 of the camera carries, on its front plate 2, a shutter 3, a diaphragm 4, serving, as explained below, for taking the views as well as for examining positives, and a front lens 5.

Within the body 1 and in contact with the rear face of the diaphragm 4, are arranged two prisms 6 and 7 with parallel faces, the edges of which cover respectively the upper and lower parts of the circular opening 8 of the diaphragm, so as to reflect marginal bundles of the rays passing through the front objective 5 and to bring these bundles of rays, respectively, opposite each of the objectives 9 and 10. The rays passing through the middle zone of the front objective 5 and traversing the corresponding part of the circular opening 8 also pass freely through the gap between the opposing edges of the prisms 6 and 7 and directly encounter a central rear objective 11.

The three optical systems comprise a converging meniscus

lens 5, common to the three lenses 9, 10 and 11, which are also formed by converging meniscus lenses carried, at a suitable distance apart, by a partition 12 located in a plane at right angles to the optical axis of the front lens 5. The optical characteristics of these lenses are so co-related that the front lens 5 forms with any one of the rear lenses 9, 10, or 11 a system which is substantially free from optical distortion.

The body of the apparatus is divided by partitions 13 into three rectangular chambers 14 located respectively opposite each of the lenses 9, 10 and 11.

Each of the compartments 14, thus formed, contains a selecting filter 16, 17, 18 interposed between two glass plates and through these screens pass, respectively the three bundles of luminous rays, of which one bundle is filtered by a blue screen, the second by a green screen, and the third by a red screen. Thus, on one and the same sensitive plate, there are produced three separate negative images, identical in form, but differing as regards the colour values recorded on them.

The prisms 6 and 7 interposed between the front lens 5 and the rear lenses 9 and 10 have each an acute angle of 50 deg. They are made of flint-glass or other substance possessing sufficient refractivity to compensate for the difference in the distances from the diaphragm 4 to the central objective 11 and to the objectives 9 and 10.

However, except by employing very dense flint-glasses, the use of which should be avoided on account of the somewhat rapid alteration to which they are subjected, owing to oxidation on exposure to the air, the total compensation necessary could not take place, if the objectives 9, 10 and 11 were located on the same plane, without increasing to an inconvenient extent the distance from these objectives to the diaphragm.

The height of the prism is, on the contrary, reduced to the minimum, so as to diminish, correspondingly, the distance which the rays have to travel within them and, at the same time, the central objective is set back sufficiently to ensure exact compensation.

As the result of this arrangement, the objective 11 is brought nearer to the sensitive plate than the objectives 9 and 10, but correct focussing of all three images is re-established by means of the glass plates containing the selecting screens 16, 17 and 18; the thickness of the glass plates through which the rays pass being calculated in such a manner that each image is in focus on the same plate.

The three selecting screens, which, as stated above, are arranged behind the objectives 9, 10 and 11, consist of three sheets of gelatine, coloured, one blue, the second green and the third red, each being cemented between two glass plates.

The prisms 6 and 7, which as above stated, divide the circular

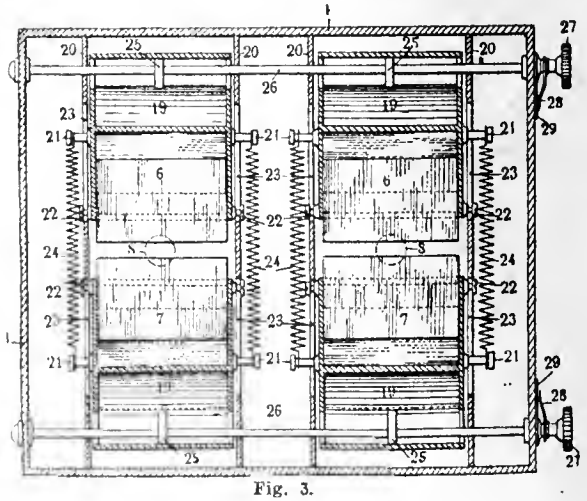

Fig. 3.

opening of the diaphragm into three portions, can move parallel to the plane of their front faces so that it is possible to vary, at will, the size of the portions of the opening which they overlap respectively. This adjustment provides means for controlling severally the intensities of the three bundles of light passing through the objectives 9, 10 and 11, thus permitting the use of any panchromatic plate having any proportions of sensitiveness to the different colours.

For this purpose these prisms are supported by mountings 19, each suitably held between two posts 20 fixed in the body of the apparatus, the connection being made by means of screws 21 and 22 engaged in slots 23 formed in these posts, so that the screws can slide freely in the slots and thereby operate to ensure accurate rectilinear guiding of the prisms.

The displacements of the mountings and of the prisms, which latter are constantly urged towards each other by coil springs 24

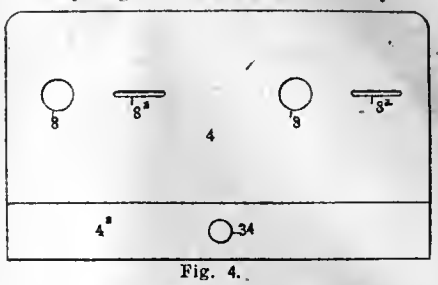

Fig. 4.

attached to the screws 21, are obtained by means of eccentrics 25, rigidly secured on spindles 26, carried by the body of the apparatus.

These spindles 26 are each provided with an outer operating milled head 27 and with a pointer 28 moving on a suitably graduated dial 29, so as to permit of exact determination of the positions of the prisms 6 and 7 and to provide means for giving them the position which corresponds to the characteristics of a given plate.

The apparatus thus constructed is provided at the back with guides 30, adapted to receive either a plate-holder or a magazine holder, or, when it is desired to examine the views, a positive holder, in which are inserted the positive views on glass; on the other hand, it is provided on its front face with guides 31, engaged by corresponding members on an eye-piece used for examining positives in the same apparatus.

The stereoscopic apparatus employs a single plate of a standard size on which are simultaneously printed six images of the same subject (three for each eye).

For this purpose, it comprises two entrance objectives 5, behind each of which is presented, as explained below, either a circular opening 8, or a longitudinal slot 8a in the diaphragm, the latter slot being intended for use only when the apparatus is used for viewing positives.

Behind the circular openings 8—assuming that the device is being used for taking negatives—are mounted, in the manner described, the two series of prisms 6 and 7 (see fig. 3) and, on the partition 12 (fig. 2) are two series of objectives 9, 10, respectively receiving the rays reflected by the prisms 6 and 7 and two central objectives 11 directly receiving the rays passing through the two front objectives 5.

The body of the apparatus is suitably partitioned at the back of the two series of objectives 9, 10, 11 so as to form six compartments, corresponding to each of the six objectives, and each containing a coloured screen.

The diaphragm for the stereoscopic apparatus is constituted, as shown in fig. 4, by two metal plates 4 and 4a, connected together, and the member 4a is inserted between two slides 33 on the front wall of the apparatus (see fig. 2). The whole of the diaphragm can thus be longitudinally displaced in the apparatus by means of the actuating knob 34, so as to bring opposite the front objectives 5 and the series of prisms 6 and 7, either the circular opening 8 for taking the views, or the longitudinal slot 8a provided in the plate 4 for the examination of the finished positives of these views.

The images obtained with one or the other of the above described apparatus are printed on an ordinary transparency plate, and in order to examine the positive thus obtained, it can be put in the place of the panchromatic plate into the apparatus in which the multiple photograph was originally taken, and the finished picture can there be viewed with the aid of an eye-piece engaged with the guides 31 on the front wall of the camera body.

When positives are viewed in the above-described apparatus, the colours seen through the screens which have been used for taking the views are perfectly true, whatever may be the light used for examination of the positives. In fact, the opening of the diaphragm being always divided in three parts by the edge

of the prisms, it is always possible, by suitably moving the latter, to effect any desired relations of intensity between the blue, green and red rays reaching the eye and to obtain, consequently, an exact reproduction of the colours, whatever may be the source of light employed. The same means may also be used to mitigate defects caused by incorrect exposure of the plate

REMINISCENCES OF COMMERCIAL COLOUR CINEMATOGRAPHY—ITS POSSIBILITIES.

(*Continued from page* 32.)

Sensitising.—I finally adopted a light revolving drum upon which was wound, automatically and absolutely equally spaced, the negative to be sensitised.

This drum, after slowly revolving in a fresh dye bath, was swung over radially into the washing water, revolved in this, and then made to take a vertical position midway between the two baths, locked in position, and rapidly spun above a current of warm air that impinged upon it.

The process proved rapid, clean and automatic. A small amount of dye bath only being required, it was possible to renew this at each operation, and a more standardised product produced, the film not being touched in any of the intermediate operations carried on in complete darkness, the drum motor driven at a slow or fast speed at will.

This same arrangement installed on a small scale to carry about 10 ft. of film, permitted me to economically make many hundreds of experiments, varying the mixture of dyes, their dilution, and study the addition of other re-agents for the purpose of increasing the ultimate rapidity and keeping qualities of the colour-sensitised negative.

The dyeing by this method was regular, and the time occupied for all operations the minimum.

Fortunately at this period Messrs. Eastman placed on the market a reliable panchro-negative film that fulfilled all commercial requirements, almost correctly balanced for standard two-colour work employing the paired screens of Messrs. Wratten and Wainwright, and I was therefore enabled to turn my attention to other problems.

The Eastman product had the colour dye incorporated in the emulsion, all tins in the same numbered "batch" appeared absolutely alike in "balance," it being necessary only to check up each batch—except in case a considerable time had elapsed since its manufacture; then a new balance had to be struck.

When old, it resensitises readily, and the result is usually more rapid than the original stock, but care must be taken when resensitising to employ a mixture of dyes that will bring up the colour-sensitiveness to a near balance, for the losses in colour-sensitiveness in old stock are not equal as regards the complementary colours.

The colour-sensitiveness of negative should always be as close as possible to a balance with the open colour screens, as any balancing by cutting out one or the other colour reduces the general rapidity.

I would warn experimenters, when dyeing ordinary stock, that all emulsions do not readily colour-sensitise. I have come across large batches that would not sensitise.

I would advise against attempting to sensitise if the marketed stock can be employed. I have seen hundreds of thousands of feet of the latter exposed and rarely a fault to be found.

Colour Screens.—To obtain better colour reproduction I made thousands of trials, spread over two, three, and four colour separation. I think I have investigated every reasonable combination possible, the lack of suitable scientific instruments forcing me to work by a process of elimination, the result on the projection screen alone determining.

In three-colour I tried a method employing the colours that are complementary to those used in the present-day three-colour photography, thus reversing the well-known process; the recording screens were minus red, minus green, and minus blue, obtaining often good colouring with very much increased exposure, but the multiple of three being difficult to handle decided me to use a four-colour separation, consisting of two pairs of complementary colours (U.S.A. patent No. 1,122,455). I made hundreds of trials, each consisting of: Exposing on a test subject; printing a positive, which then, formed into an endless loop, was projected for any desired length of time, in conjunction with both two- and four-coloured screens.

The range of colours and tints obtained by this method, when a four-colour or even a two-colour cycle is employed in projection, is much increased, and most of the pictures shown by Prizma were the result of exposure under cycles of *four* differing colours arranged as two pairs of complementary, the negatives being transposed into the form of a *two*-colour dye-toned double-coated positive.

A little more care is necessary when balancing the four-colour screen with the panchro negative, the screen containing the maximum blue having to be watched.

Exposure. The question of exposure is of vital importance in colour cinematography. Normal colour screens of sufficient density to give the necessary amount of colour separation multiply the exposure from ten to fourteen times, and there are only two methods to overcome this—increasing the duration of exposure without changing the number of impressions per second, or radically altering the medium by which the colour separation is achieved.

The first method was one of easy solution. I had built colour cameras employing the Geneva movement with a pull-down fully covered by a quarter shutter (90 degrees), which is half that of the usual type of claw pull-down employed generally in black and white. This yielded at once 50 per cent. more exposure, and cut down the colour fringing to a minimum, for it shortened the interval of time between each exposure.

Very few Geneva movements will stand 32 per second without vibration. After several trials I found that the movement embodied in the Simplex projector gave every satisfaction, and the several cameras built for Prizma having this movement gave steady, sharp negatives, as their pictures show.

I tried several accelerated claw movements, but at high speeds the vibration was too much, even when the mechanism was carefully balanced.

The attempts to make cameras to stand this work with a one-tenth pull-down (36 degrees) also failed. I think the practical limit is reached at somewhere round 90 degrees.

The question of changing the *character* of the colour sensations separator proved much more difficult. The Lumière method of starch grains, the various colour line screens, or their equivalent, require even greater exposure or bring in a new series of complications.

After much patience I succeeded in finding and working out to a practical conclusion a novel method of colour separation, that, whilst fulfilling our definition of necessary colour rendering, gave an exposure that lies between black and white and that of normal colour screens.

I say "novel," because the U.S.A. patent office after first refusing the application for protection on the grounds of being "inoperative," later granted claims for a patent that on the face appears to be a "basic" one.

By repeating the first claim of the patent granted, the process is simply explained :—

"The method of recording colour values which consists in exposing a panchromatic emulsion to both coloured and substantially white light."

Instead of employing a standard colour segment, of, for instance, red, the new screen was composed of a composite segment that consisted of a red screen having a radial slot cut out in its centre. This open space is covered by a "K1" or "K2" colour screen. The green segment (in a two-colour process) is treated in like manner, the slots in both colours being absolutely equal.

Thus every single picture recorded by this means consisted of a colour impression *plus* a black and white impression, the "K" screens serving to filter out the excessive blue-violet rays.

One would imagine, as the examiners of the U.S.A. patent office did, that the "white light" impression would bury or block out the colour impression—it does so to the eye—but the latent colour values are there, and the negative when printed from gives by additive light-projection with normal colour screens, a smooth running picture, full of colour and of great sharpness, and when transposed to double-coated film by dye-toning the results can be judged by those who have seen the Prizma pictures that embody this principle in combination with that of the four-coloured method of taking as previously explained.

An orange photographed with normal colour screens, in bright sunlight, full aperture (*f*/ 3.5) gives for the red impression a nearly fully-exposed image, lacking slightly, however, in the deepest shadows. The green impression would be very faint and entirely lacking in details.

I have a negative of a close up of an orange, recorded with these composite screens. The objective was stopped down to *f*/8. Other conditions being the same, both the red and the green impressions show the fruit as a fully-exposed rounded form, the red impression appearing slightly stronger than the green, and yet on the projection screen the orange stands out in full-coloured relief, and of a much more natural hue than it would have been if recorded with a pair of normal colour screens at full aperture and same speed.

Strangely enough the theoretical calculation of what the exposure factor of these composite screens *should be* as compared with normal colour screens does not account for the practical difference gained in exposure. In actual experience extending over several hundred thousand feet of negative taken by this method of increasing exposure and retaining colour, I have found the all-round gain in visible exposure is beyond the figures arrived at by calculation. This may be due to the fact that when once the point of under-exposure is reached in colour-screen work the curve falls off rapidly.

Later research has shown me that the exposure factor can be reduced still further, and the colour factor increased by still other means, that I hope to indicate later.

In California I conducted a series of experiments in some of the largest black and white studios, for the purpose of finding the limitations in colour working, under practically black and white conditions.

Using thin sheeting as top diffusers, of sufficient thickness entirely to break up shadows, with lens stopped down to *f*/5.6 in sunlight, the composite screens recorded full exposure with good colour, employing Eastman's normal panchro negative stock.

I found the white reflectors, as usually employed in these studios, were useless for colour work. I therefore, after experimenting, made reflectors by coating screens with one coat of aluminium paint, followed by two coats of gold paint (light bronze). These screens proved of great utility, in scenes and in close ups, accentuating the colour and increasing the exposure, and were less objectionable to the eyes of the victims than the white ones. CHARLES RALEIGH.

(To be continued.)

AUTOCHROME LANTERN SLIDES.

THE very fact that a colour transparency is seen upon a much larger scale greatly widens the scope of the process in regard to the subjects that may be undertaken. Very much wider expanses may be included in the picture successfully than would be the case if the picture were to be viewed in its original size. It is well known that landscapes are particularly disappointing when viewed in this way, though, when projected, all the beauties of the original may be seen fully in evidence.

For an Autochrome transparency for projection a full (slightly over) exposure is necessary, coupled with a full development in the first bath. It is also essential to use a developing formulæ that will produce a very brilliant result in regard to colour, without producing an unwanted density. An Autochrome transparency that is over-dense is often fairly satisfactory when viewed in the hand if the *colours* are sufficiently brilliant, but such gives very poor results when projected upon the lantern screen. The Quinomet concentrated developer, issued and specially recommended by the makers of the plates, has no equal; and Rytol used as directed by Messrs. Burroughs Wellcome & Co. in "The Photographic Exposure Record," is also entirely satisfactory. The following formula recommended by Mr. A. B. Hitchins is also excellent for Autochromes required for projection. It produces a very clear, transparent and brilliant positive.

Metol	6.5 gms.
Soda sulphite, anhydrous	40 ,,
Hydroquinone	2.1 ,,
Potass bromide	2.5 ,,
Ammonia, .880	20 c.c.s.
Potass ferrocyanide (not ferricyanide)	4.1 gms.
Water	1,000 c.c.s.

Development should be very full, and the action should be allowed to continue for four or five minutes. The following reversing bath is recommended :—

Potass bichromate	4 gms.
Sulphuric acid	15 c.c.s.
Water	1,000 c.c.s.

Redevelopment should be carried out in a good light with the following at a temperature of not lower than 60 deg. F. :—

Soda sulphite (anhydrous)	21 gms.
Diamdophenol	6 gms.
Potass bromide, 10 per cent. solution ...	100 drops
Water	1,000 c.c.s.

Sufficient time must be given for the image to be fully out, the plate being left in the solution for four or five minutes. A clearing bath should then be employed; among the best is a 1 per cent. solution of bi-sulphite of soda, or, if the worker is in the habit of using the acid permanganate reversing bath, this may be diluted to a pale pink colour (about twenty times its own bulk of water), but the plate must not be left in this bath more than twenty seconds, or reduction of the image will occur. If the plate has been fully exposed and treated exactly as above the final result should be thin, though with the colours sufficiently brilliant for satisfactory projection as a lantern slide.

The worker may decide whether the plate (after clearing) is in need of any further after treatment. Reduction may be necessary if the plates are at all under-exposed, though it is unlikely that an under-exposed Autochrome will be ever satisfactory for lantern projection. If, however, it is decided to reduce the plate, Farmer's reducer may be used, or the reversal solution diluted with five times its own bulk of water is effective. It is more than likely, however, that the plate will need intensification in order to be brilliant enough for lantern projection. It must be kept in mind that though the colours may seem bright when viewed by transmitted light, the magnification of the image when projected tends to reduce the quality and brilliancy of the image to a greater degree than most photographers are prone to imagine. The Lumière pyro-silver intensifier is undoubtedly the best, for its specific effect is to increase the brilliancy of the colours. If the plate is already dense and the worker fears that pyro-silver may add too much to the image, the chromium intensifier should be used, as its action is more easily judged and controlled.

Few Autochrome workers to-day varnish their transparencies; but this should be regarded as essential when preparing Autochrome for projection, for it brightens the image, renders it more transparent, increases the brilliancy of the colours, and has a slightly protective effect. Previous to varnishing, the plate should be soaked in a solution of chrome alum. Spotting out should be done after varnishing, using transparent colours, and these should be applied very carefully. R. M. FANSTONE.

REMINISCENCES OF COMMERCIAL COLOUR CINEMATOGRAPHY—ITS POSSIBILITIES.

(*Continued from page* 36.)

Projection Apparatus.—After many trials I adopted a Simplex projector, in its usual form, with a three-bladed shutter, or for still higher speeds the special form designed for the late American Kinemacolor Co., having a two-bladed shutter and a slower pull-down. These mechanisms are about the only ones that would stand up to the wear and vibration of over 32 per second.

I designed a colour wheel attachment that could be readily attached to any standard Simplex or Powers projector, these two machines being used in the greater proportion of the principal theatres in the United States.

For colour screens I dyed up thin fixed lantern plates, hardened the gelatine, cut them to segments and cemented them to thin cover glasses, and by employing only the highest class fast dyes, these screens gave superior results to the previously-employed gelatines, using less current, producing a sharper picture, and lasting sometimes for months.

I had constructed a mechanism that enabled the operator to "change colour" instantly whilst running at full speed, and a very clever job Casler made of this. I designed a simple addition that enabled the operator to thread up his projection machine always on correct colour and to the frame line. A round hole was punched in the centre of the first red picture of a reel, this hole being threaded on a movable pin that protruded from the aperture plate of the machine, and the operations of threading up continued. Upon closing the gate the pin retired and left the colour film in correct position as to colour and to exact frame line.

Although these alterations removed many of the objections that were associated with Kinemacolor, and the result on the screen was excellent, the process was not commercial, and the demand was for "colour in the film" and no fringing of colours.

One of the earliest workers who attempted to meet this demand was Fox, originally associated with Kinemacolor. He was bold enough to attempt the following:—

Fox took a Kinemacolor negative, and printed from this the alternating red impressions on a strip of ordinary positive, developed and toned it blue-green, waterproofed and recoated it with emulsion, printed the green impressions, tone-dyed them red, thus producing one of the first "colour in the film" positives. Later he varied somewhat his operations and built a camera with two lenses to avoid colour fringing, but came up against "parallax," and had a brand-new form of colour fringing which attached itself to stationary objects.

Arturo Hernandez-Mejia was one of the next victims. He invented or, at any rate, claimed to be the first who employed a double-coated positive film, the red colour values being printed on the one side, and dye-toned blue-green, the green colours printed on the other side and dye-toned red. He also employed at first, a celluloid base tinted yellow, to avoid confusion in printing and neutralise any excess of the blue rays of the arc in projection. A full account of this process and his hopes were published in the "B.J." of October 18, 1911.

Messrs. Eastman in a quiet way produced some samples of colour in the film, on double-coated stock. I think it must have been a kind of bait, for they then settled down to placing on the market a practicable double-coated film stock.

Prizma, after a study of the most promising methods adopted by the several workers of "colour in the film," selected that of Hernandez, and at that time, having strong financial backing, were enabled to build extremely accurate double printing machines, the credit of which belongs to Messrs. Mason, Kelly and Casler. They also constructed machines for the continuous automatic tone-dyeing of both sides of the film. They employed Eastman's double-coated stock and printed from negatives made with the Geneva movement camera and composite colour screens as previously fully described, and have for the last two years been experimenting to produce a non-fringe camera. They certainly had pluck, having sunk not far from three-quarters of a million dollars in cash in the chase after commercial colour cinematographic pictures.

The commercial value of a colour process cannot be determined by the appearance on the projection screen, even when the costs per foot are given.

A mixed programme may appear satisfactory as regards:—

(*a*) Variety of subjects, but you must know the conditions of exposure.

(*b*) Colour rendering—the results may be pleasing, but far from true.

(*c*) Sharpness, only when shown accompanied by rapid movements, can indicate the value of the optical system employed.

(*d*) Freedom from fringing can only be judged when the action of close up movement is normal, and not purposely slowed down.

R

It is necessary to analyse the conditions under which the product was made and exhibited, and, *above all*, know the quantity of negative stock utilised over a considerable time period, covering a variety of subjects, and the class of labour employed in the production.

Losses in colour work far exceed those in black and white, and are due to greater exposure factor, the chemical and mechanical process of dye-toning and unskilled labour.

The number of operations are increased, the limitations are greater, and the practice necessary is only acquired at the expense of time and material.

As regards the exhibition end, if the product is widely distributed, will it stand up to the wear and tear employed in the projection machines?

In most machines wear is purposely confined to the celluloid side of the film. Few models are constructed on principles that treat with equal care both sides. Therefore the free running under working conditions of a product that possesses two emulsion surfaces must be confined to those projectors in which an ordinary black and white film can be run (under working conditions) with either celluloid or emulsion side towards the objective, without damage.

Those who hope to succeed financially on a large scale must improve present *exposure conditions* by obtaining colour separation under methods having a less exposure factor than the present procedure, and these colour separations must be obtained simultaneously. The product, to have a maximum life, should carry the colour values on the one side, so that a celluloid surface can carry the wear of all manipulations and handling from manufacture to projection.

To those workers who are content to specialise only in subjects that lend themselves to the present common knowledge conditions, I would advise the taking up of the double coated positive already on the open market, avoiding the particular methods described in the latter patents. They can find plenty of means to dye-tone and produce many pleasing results.

There is usually much difference between what the patentee says he owns and what his specification limits him to.

Ten years ago dye-toning was a more complicated affair. I remember when it was necessary to use five or six different baths, with intermediate washings, some of which had to be very thorough. To-day it is possible to dye-tone in any colour, employing but two baths, the whole operation, including one rinse and one after-washing, requiring but twenty minutes, and this from a faint silver image. The process is very fascinating, and I have made many thousands of samples.

Starting with the well-known formulæ, and with a varied supply of reagents, it is not difficult to discover modifications and variations; one of the peculiarities of well-known formulæ is that one rarely gets satisfaction from following strictly the method given, and many such may be made to give excellent results with a little patience.

The chemicals employed in mordanting, and their order of mixing, have much to do with the rapidity of after-washing, as also the particular dye employed. Hypo should not be used for clearing; clear, bright-coloured images absolutely transparent can be obtained without it.

The variations of the working of dyes, even of the same colour, are very great, some washing out quickly with one mordant and not with another.

When mixing dyes to obtain a desired colour care must be taken that the mixture is one that gives uniform graduations of colour. Some mixtures favour one colour in the high-lights and the other colour in the shadows, which is bad for balancing, for it must not be forgotten that the complementary dye colours must balance in the same manner as was mentioned in making the colour negative, but in this case, being a subtractive method, the result must form a black.

Very interesting combinations can be obtained by combining chemical and dye toning. The variations in the result are infinite, the high-lights and shadows favouring different colours.

For experimenting with short lengths of double-coated positive, when desiring to dye-tone each side of a complementary colour, I found the easiest method was to protect one side temporarily with a strip of Johnson's adhesive plaster (india-rubber base) that can be obtained one inch wide, the ideal width, as it protects only the area inside the perforations.

In conclusion I would add that although many mordants and many dyes make satisfactory samples, it is not every one that will dye-tone in a commercial manner a long length of film, and wash out rapidly and evenly.

CHARLES RALEIGH.

BLUENESS IN AUTOCHROMES.

[In a recent issue of "Le Photographe" is a paper by M. Eugène Muller, read before the Photo-Club of Alsace and Lorraine, in which the author records his observations on the occurrence of a predominant blue tint in Autochrome transparencies, and of the means which he found effective for its avoidance.]

It was found that a particular batch of Autochrome plates of the year 1920 showed a marked bluish tint, an observation which occasioned the writer to go into the subject, although the existence of the tint was denied by MM. Lumière. In later work it was noticed that the Autochromes no longer exhibited this predominant tint, the reason for which was found to be that, by an error, a Von Hübl light-filter of greater depth than the standard one for Autochrome work had been employed.

As regards variation in the mosaic screen itself of the Autochrome plate, this is an unimportant factor, and M. F. Monpillard has already remarked that the cause of a predominant blue tint is to be sought elsewhere, namely, in a difference in the colour-sensitiveness of the emulsion. It is, of course, obvious that if the colour-sensitiveness for red-orange rays is diminished from any cause, the use of the standard light-filter will give rise to a predominant blue tint in the transparencies.

This blue tint may be corrected, or even completely avoided, by one or other of several means. As has been suggested by M. Schitz, the Lumière light-filter may be supplemented by one of the Wratten K1 screens, employed, in addition to the standard Lumière filter, for about one-quarter of the exposure. M. Monpillard has also found that the Auto J screen of his manufacture, if used in conjunction with the Lumière screen, for the whole period of the exposure, is satisfactory.

My own preference has been for the use of a single screen somewhat deeper than the Lumière standard. Having a variety of screens at hand, I made a series of tests by photographing the same subject successively with different screens. A white object was always included, since the rendering of white may be readily observed, and a screen is found to be correct if white is rendered as white. A range of grey objects of different depths was likewise included, since any predominant tint makes itself more evident over parts which should appear as grey.

As a result of these tests, made by using Autochrome plates derived from nine different batches of emulsion, it was found that in summer the Autochromes made with the standard Lumière screen gave a bluish tint, even when exposure was correct or in excess of the correct time. The tint shows itself more or less strongly

according to the variations of the emulsion, and also to those of the illumination at the time of making the exposure. This latter was examined with the "coloriscope" of Von Hübl, and was never found to be pure white. However, notable variations in the bluish colour of the prevailing light could be observed. As a general rule this blue coloration is less intense when the sky is pale blue, with some clouds or completely clouded, than when it is very blue. But on certain days it could be observed that the blue colour of the prevailing light was as intense with a lightly clouded sky as on another day when the whole sky was a strong blue.

Tests made with the Monpillard Auto J. screen, such as was adopted as a standard by M. Monpillard before the war, gave a prevailing yellow tint with the recent Autochrome plates which I used. The explanation of this unexpected fact has not yet been found. Likewise a prevailing yellow tint was obtained with a Von Hübl screen of much greater depth than the normal, the time of exposure being increased by slightly over 50 per cent. But the transparencies obtained, despite a slight yellow tint in the whites, are of more agreeable colour rendering than the colder results obtained with the standard Lumière filter. A screen such as this appears to be suitable for specially blue conditions of light, such as occur, for example, in the photography of snowscapes, where the shadows are very blue.

Of all the other screens which I have tested, the most notable is undoubtedly the Von Hübl filter, having a slightly greater depth than the standard. The time of exposure requires to be increased by about one-fifth. The depth of this screen is only a little greater than that of the standard. Looked at by reflected light (laid on a sheet of white paper), it appears identical with the standard Lumière filter and does not show the reddish tint of the normal Von Hübl screen. In fact, it appears clearer than this latter. But examined by transmitted light its colour is yellower than that of the standard Lumière and Von Hübl screens, which are identical in appearance when viewed by transmitted light. This arises from the fact that only the yellowness in the screen is greater, whilst the red is the same as in the normal Von Hübl screen. The following are the formulæ for the normal screen and for the B, as given by Von Hübl in his "Theorie und Praxis der Farbenphotographie."

	B screen.	Normal screen.
10 per cent. gelatine solution	38 vols.	40 vols.
Filter Yellow K, 1 : 200 solution	16 ,,	14 ,,
Solid red D (Echt-rot D Hoechst) 1 :2,000 solution	16 ,,	14 ,,

The coloured gelatine solution is flowed on to glass in the proportion of 7 c.c.s. per square decimetre.

With this somewhat deeper screen the transparencies obtained on eight different emulsions, out of nine which were used in the month of June, were free from bluish tint, both with a blue sky and with one which was completely clouded, whilst the same subject photographed at the same time with a standard screen invariably showed the bluish tint. The ninth emulsion differed from the others in that it yielded a bluish tint even with the deeper B screen of Von Hübl. On the other hand this emulsion required at least double the exposure as compared with the others exposed under the same conditions of light.

Whilst the bluish tint appears when the old standard screen is used for daylight exposures, such is not the case when employing artificial illumination from a light rich in yellow-orange rays and containing a sub-normal proportion of blue and violet rays. These latter, being less intense in comparison with the others, the blue tint does not appear. Transparencies made on recent Autochrome plates, using a Nernst lamp with the special Von Hübl screen, or Perchlora flash powder with the Lumière Perchlora screen, showed no trace of a blue tint.

EUGÈNE MULLER.

A TWO-COLOUR PROCESS OF ADDITIVE COLOUR CINEMATOGRAPHY.

[The obtaining of more perfect blending of colours, and the possibility of making colour films to normal artificial light, are claimed in a recent patent specification No. 183,150, in the name of Messrs. R. O. F. Humphrey and Claude H. Friese-Greene. The invention provides a rotating disc, having an aperture admitting white light, with which is incorporated a section or phase of blue filter, and also a red filter section. The red filter is graded in density, so that the densest end is slightly deeper in colour than the actual depth required by a filter of constant density. Exposure therefore commences, to light of low intensity but correct colour, and gradually increases in intensity as the shutter moves across the lens. The blue filter, which is used in conjunction with the aperture admitting white light, is intended to increase the colour value on the blue side. This filter can be varied in area or intensity to suit any particular conditions of light, or nature of subject. The positive pictures are coloured in the usual manner, those taken through the colour filter being tinted orange-red, and those exposed to white light with the colour phase, tinted blue-green. The resulting pictures may be shown at a speed more approximating that at which the usual black and white picture is shown. But it is suggested, that it is desirable in practice, to speed up the intermittent motion of the camera so as to lessen the time taken in moving portions of the film successively into position for exposure. This "quickening up" of the motion of the film allows the use of filters of large area, thus increasing the speed of exposure and reducing colour fringing to a minimum.]

The usual disc containing two apertures is utilised, and is rotated at half the speed of the shutter. One aperture allows the passage of white light with a colour phase, which may suitably be of a blue-green shade. The other aperture is filled with a transparent filter coloured for example a shade between yellow and red. The aperture allowing the passage of the white light with a colour phase, is preferably adjustable in area so as to obtain a balance with the colour filter. Such aperture may be sub-divided into two or more apertures, if desired, which further apertures are preferably disposed on the opposite sides of the line passing through the axis of the disc and the middle of the aperture containing the colour filter. The essential is that the total of the areas of the subdivided apertures should approximately equal the area of a single aperture when such only is employed.

By sub-dividing the aperture allowing the passage of white light with a colour phase into two or more sections, and by disposing two of such sections as close as possible to the ends of the aperture containing the colour filter, displacement is minimised between the two pictures taken during each revolution of the disc and, as a consequence, colour fringing in the projected positives is also minimised.

In practice, the best results are obtained by gradually diminishing the intensity of the coloured filter from one end of the aperture to the other, the exposure being made either first through the densest end of the filter or through the lightest end.

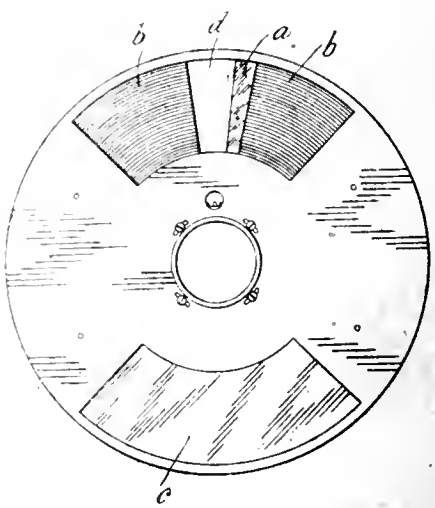
The gradual varying of the density of the colour filter is of great practical importance, inasmuch as it operates to reduce the period of exposure which would otherwise be required were the light passed through a filter in which the required colour was of uniform density. The colour at the densest end is slightly denser than the colour which would normally be required in a screen of constant density. The first part of the exposure is thus made with light of a low intensity, but of the required colour, which light then gradually increases in intensity as the aperture is moved across the path of the light passing through the lens.

It will be seen that the essential feature of the invention is the taking of one picture through a colour filter adapted to exclude white light but to transmit light at the red end of the spectrum,

and the taking of the other or succeeding picture by exposing the particular surface of the panchromatic or colour sensitive emulsion to white light with a colour phase which is of less value than the white light.

The positive pictures are coloured in the usual manner, the picture taken through the colour filter being tinted orange-red, and the picture taken by exposure to white light with a colour phase, being tinted blue-green

In the drawing *a* represents a blue-green phase, *b* a filling of



opaque material, and *c* a colour filter the colour of which is on the red side of the spectrum.

The following is one complete application of the invention when using the arrangement illustrated in the drawing.

Area of white light aperture = .6233 sq. inches.

Area of blue-green filter = .255 sq. inches.

The blue-green filter *a* is coloured with the following solution :—

Solution A :—

Rapid green	10 grs.
Distilled water	10 ozs.

Solution B :—

Patent blue	10 grs.
Distilled water	20 ozs.

These solutions are mixed as follows :—

1¼ ounces of Solution A and 1¾ ounces of solution B. To this mixture is added four ounces of distilled water.

The transparent filter material, preferably having a gelatine base, is immersed in the above solution for one minute, after which it is rinsed in distilled water for fifteen seconds and then allowed to dry.

Filter c is coloured by immersion in the following solution :—

Flavazine T	10 grs.
Distilled water	10 ozs.

The flavazine T is dissolved in the distilled water. The solution is applied to the filter material by means of a brush so as to obtain the gradual effect previously referred to in this specification.

The density and area of the colour filter c is determined by test so as to balance with the aperture for white light and the blue green colour phase.

The positive film is coloured by direct application of blue-green and orange-red colouring alternately, the blue-green being applied to the portion of the film corresponding to that portion of the negative which has been exposed to light passing through the white aperture and the blue phase and the orange-red to the portion of the film corresponding to that portion of the negative which has been exposed to light passing through the flavazine filter. One suitable solution for colouring the blue-green picture is as follows :—

Solution A :—

Rapid green	10 grs.
Distilled water	10 ozs.

Solution B :—

Patent blue	10 grs.
Distilled water	20 ozs.

To a mixture of one ounce of solution A and two ounces of solution B add two ounces of distilled water.

The solution for colouring the orange-red pictnre is as follows :—

Solution A :—

Fast red D	10 grs.
Distilled water...	11 ozs.

Solution B :—

Flavazine T	10 grs.
Distilled water	10 ozs.

To a mixture of three ounces of solution A and half-an-ounce of solution B add three ounces of distilled water.

TRIPLE COMPOSITE PLATES FOR THREE-COLOUR NEGATIVE MAKING.

THE old process of preparing three separate colour sensitive emulsions, coated on one support, their colour sensitiveness being so adjusted that three-colour negatives may be obtained at one exposure. introduced by the late Dr. J. H. Smith (English patent 19,940, 1904), and demonstrated by him befors the Royal Photographic Society, has been revived by a German inventor. This patent, No. 183,189, in the name of Ernst August Lage, provides for a plate for tricolour photography, which comprises three films placed upon one rigid support, which can be separated when required. The three separate sensitive surfaces are pressed into optical contact by means of rubber rollers, which press out the air between the layers, after the edges of the glass plate, used as a support. have been moistened. The combined plate can then be exposed as one surface, and when required for development the two separate films may be detached. The three sensitive surfaces are then developed in the usual way.

This invention provides for an improved method of producing photographic plates comprising three superposed colour sensitive films. Three silver emulsion colour-sensitive films (sensitized for the different spectral divisions) are prepared separately, are then superposed directly upon each other and are pressed into optical contact by pressing out the intervening air.

It is preferred to prepare one emulsion upon glass, whilst the other two emulsions are applied to very thin films. The films may consist of celluloid, collodion, coloured gelatine, mica, etc.

The thin films are placed upon the lower silver bromide plate, the intimate contact between the plates being produced by pressing out the air from between the films. A suitable mode of working is the following :—The emulsion side of the glass plate is wetted at the edge all round. The first film is then placed upon the table, with the emulsion side upwards, and the film, together with the plate, are then pressed against one another by one or more rubber rollers, which press out the air between the layers which are to be brought together. The second film is then superposed in the same manner, whereupon the plate is ready for exposing.

The lower emulsion which may be carried by the glass is a highly sensitive bromide emulsion sensitized for red rays; upon it lies a film sensitized for yellow, green and blue rays, whilst the uppermost film is sensitive to blue only. The filter layers, should any be required, are placed upon the rear sides of the emulsion carriers, preferably in the form of easily washed out colour layers of gelatine.

In order to develop the plate it is sufficient to make a slight incision upon the lower side along the edge. The several films are then easily separated, and may be developed and treated in the usual manner.

It would seem that the process described in the foregoing specification is that which contributes in part to the method which was recently brought to the notice of photographers at the trade exhibition in the Professional Photographers' Association Congress by the Peerless Photo-Paper Co., Ltd., of Rickmansworth. At that exhibition we learnt that the three-colour-sensation negatives are made at one exposure in an ordinary camera by means of a triple sensitive material which consists of two emulsion-coated celluloid films of extreme thinness mounted upon an emulsion-coated glass plate. That, however, is only half the process, since the Peerless Photo-Paper Co. have a method of their own of making a colour print from this negative set on a single sheet of development paper.

THREE-COLOUR TRANSPARENCIES BY COMBINED CHEMICAL TONING AND DYE PRINTING.

[At the recent exhibition of the Royal Photographic Society a medal was awarded, in the colour section, to a transparency by Mr. Frederic G. Tutton, who has now given working details of the process in the November issue of the "Club Photographer." By courtesy of our little Liverpool contemporary we reprint his paper.]

So much has been written and said about the making of a natural colour transparency by the Paget and Autochrome screen plate processes, that the average photographer does not know that there is another method whereby some of the most beautiful and brilliant transparencies can be obtained, and even in the lantern show upon the screen with a brilliancy not to be surpassed by either of the two methods mentioned above. This process is termed three-colour or tri-colour photography, and, in the author's opinion, results can be obtained, particularly against the light, that far surpass either of the present-day screen-plate methods.

As this paper is written particularly for the tyro who knows practically nothing about colour work, perhaps a short explanation of the theory of colour photography may help him to grasp the few essentials to success.

You probably all know how by means of a spectroscope the composition of white light may be studied, how on looking through this instrument a continuous band of colour is presented to the eye, commencing with red, through orange, yellow, green, blue, until finally violet is reached. You also have probably heard of the theory given by Dr. Thomas Young and Professor Helmholtz, namely, that all these colours may be formed from three fundamental or primary coloured lights—red, green and blue-violet. Tri-colour photography, then, is based on the principle that all colours occurring in nature can be split up into three primary or fundamental colours—red, green or yellow, and blue can be formed again from these. If the image of a coloured object is split up photographically into three constituent images, of which one produces only the yellow, another only the red, and the third only blue parts, these monochromes will, if properly superimposed, give a representation of the objects true to nature. To split up the image into the three primary colours, light filters or colour screens are used, and these screens are so adjusted that if in the path of the ray of light which forms the image on the plate a blue filter is inserted, it transmits all rays except yellow. In other words, the negative when developed will have the red and blue represented by a deposit, but the yellow, or any colour containing yellow, will be represented by more or less bare glass; thus the positive from this negative will only produce the yellow print. During the exposure, a green filter, which only transmits green, blue and yellow, but absorbs the red, is used. In the negative thus obtained, green, blue and yellow will be represented by a deposit, and red, clear glass. In printing we shall obtain a red transparency. Finally, to obtain the blue an exposure is made behind an orange or red filter, which transmits red and yellow and absorbs blue, the negative will show red and yellow dense and the blue clear glass, thus giving the blue positive.

Filters already adjusted can be obtained from most makers of panchromatic plates, and it is advisable to purchase the filters from the makers whose plate you decide to use.

Having exposed your plates behind the respective filters, the plates should be marked in some way—in the dark room, of course—so that when developed you will know which filter was used for the particular plate. In the author's own practice he always marks on the corner of the plate I. for red filter, II. for green filter, and III. for the blue-violet filter. The plates are always exposed in this order. Exposure should be full, so that details in the shadows are recorded, and the plates should be developed together at one and the same time. Development should be aimed to produce a fairly soft negative; hard negatives are apt to render the resulting transparency somewhat hard, with detail lacking in the high lights.

Now comes the part of the process where the skill and personality of the worker play an important part, and that is the making of the transparency. Personality is put here, as by the method to be mentioned the worker has it within his hands to alter, within limits, the result of the transparency, whether too much or too little of any one colour is required, or whether the whole is required to be brilliant or somewhat dull.

There are several methods of producing three-colour transparencies, but the one given below is about one of the simplest and most economical.

From the negative taken with the red filter a transparency is made in black and white upon an ordinary lantern plate; a somewhat denser image should be aimed for, as during the subsequent bath it loses a little in depth. It should be well fixed, and washed for at least half an hour in running water. It should then be placed in the following bath:—

Ammonium ferrous oxalate	8 grs.
Potassium ferricyanide	8 grs.
Glacial acetic acid	84 m.
Water	3½ ozs.

In this solution the image quickly assumes a blue tone. It should then be washed for a short time and immersed in an

... bath to remove the silver compound. Too ... is not advisable, as the bath attacks the ... and gradually dissolves it away. After well washing, it should be placed for one or two minutes in a 1 or 2 per cent. solution of hydrochloric acid; the colour is converted by this into a brilliant greenish-blue. The plate should now be washed in repeated changes of boiled or distilled water and dried.

To produce the yellow image, a positive transparency from the blue filter negative is made with films, using either the roll film variety or one of the flat films now on the market. If dried after fixing and washing, it should be thoroughly wetted and placed in the following bath:—

Stock Solution.

(A)	Potassium ferricyanide	124 grs.
	Water, boiled or distilled	3½ ozs.
(B)	Lead nitrate	124 grs.
	Water, boiled or distilled	3½ ozs.

Working solution A 1 oz. 6 drs., B 95 mins. Acetic acid, a few drops. This bath should be filtered if it becomes turbid.

The film should not contain the slightest trace of hypo, otherwise spots will form. The image will bleach out white, and then appears to be intensified to a notable extent, and for this reason the transparency should not be developed too strongly. When bleaching has penetrated through the emulsion, well wash until all trace of yellow stain has disappeared, then place in the following bath for a few seconds:—

Stock Solution.

Potassium bichromate	37 grs.
Water	3½ ozs.

Take one part of above to one part of water.

Wash again until all yellow stain has gone from the high lights, and dry. Varnishing this film with one of the transparent varnishes on the market renders the image more transparent.

It is in printing from the green filter negative for the red constituent image that rather more skill is required. Old and useless films should be fixed out in hypo with a little potassium ferricyanide to clear the emulsion from fog, well washed, and dried. They are then immersed for two minutes in the following solution at 60 deg. F.:—

Ammonium bichromate	27 grs.
Strong sulphuric acid	6 drops.
Water	2 ozs. 1 dr.

Rinsed in clear water and dried in the dark.

Printing is carried out in daylight until the image is well seen in a brownish colour; it is then removed from the printing frame, well washed for half an hour in frequent changes of water—not running water. The film should then be immersed in the following solution:—

Magenta red dye	16 grs.
Hot water	4 ozs.
Acetic acid	10 mins.,

for about twenty minutes, so as to give the chromated image plenty of time to take up the dye. Rinsing in water made acid with acetic acid until the high lights are clear of the dye completes the operation for the red film.

We now have three positives in their respective three colours, namely, blue upon the glass, and a yellow and red film, and all that now remains is to superimpose the three images on top of one another to complete the picture in all its natural beauty.

The blue slide is first placed in a retouching desk with the film uppermost; upon this is laid the yellow image, and moved about until the two images are in register; a little touch of seccotine is placed on the underside of each corner of the film, and the two pressed well into contact, a cover glass is laid over, and the whole put under pressure for about 24 hours for the glue to dry. Laying the yellow image should be done in daylight, as it is very difficult to see the yellow image during artificial light. We now have the picture in two colours, and if carefully superimposed no fringing of the colours will show. It now remains to fit the red over the green image, which is done in exactly the same way as with the yellow film, but in this case the picture will be seen in all its original colours; after cementing the corners and leaving to dry under pressure for 24 hours, the picture is masked and bound between a cover glass with lantern strips.

Anyone making these transparencies for the first time will be astonished at the results—shadows are transparent, high light with colour, and the resulting picture more or less under the control of the worker.

The above operations sound more difficult than the operation really is, and the author trusts that it may be the means of inducing many others to take up this branch of photography. The difficulties, if any, are easily overcome with a little practice and patience, and when once a fair start has been made, and the subject thoroughly grasped, there are but few who will have any desire to abandon the work.

FREDERIC G. TUTTON.

THE GORSKY CAMERA FOR COLOUR CINEMATOGRAPHY.

[The patent specification, No. 185,161, for the optical system of a camera for colour cinematography, invented by Professor S. M. de Procoudine Gorsky, and previously mentioned in the Colour Photography "Supplement" of January 6, 1922, p. 4, has now been published. This system consists of three rhomboidal prisms, cemented together to make one combination prism, which is arranged in front of three separate lens systems. Two of these prisms are coated with a reflecting band of silver, and thus three separate pencils of light traverse parallel optical paths, and are then taken up by the three lenses. As the distances which the rays travel are not equal, correction has to be made, either in designing the objectives or in adjustment of their focal lengths, but in a suggested modification to suit a camera taking three separate bands of film this is unnecessary. Three films in this adaptation are fixed at unequal distances from the prisms, so that the optical distances become equal. In a further modification of the system, two prisms only are used, as in fig. 3, and by this means it is claimed that a greater volume of light is allowed to reach the films. The novelty of this optical system is that the original image, received by the first prism, is split into three separate images before entering the lens system, and the corrections which are made for distortion, caused by the prisms, enables three identical images to be recorded on the sensitive surface.]

THE invention consists of an optical system for a photographic camera, comprising a series of rhomboidal prisms arranged in such manner that the light-rays from the object are reflected so as to form three identical images on three picture areas of a sensitive surface. The parallel faces of the prisms, which are coplanar, are provided with a substance having a refractive index differing from that of the glass, or a partially-silvered surface to act as a partial reflector. The reflected rays are passed through lenses situated at varying distances from the prisms and the sensitive surface of the film or films.

Fig. 1 illustrates a method suitable for the simultaneous production of three identical images upon one cinematograph film;

Fig. 2 illustrates a method suitable for the simultaneous production of three identical images upon three separate cinematograph films;

Fig. 3 is a modified form of the invention illustrated in fig. 2.

In fig. 1 the film passes through a gate frame, A, of the usual form having three apertures, A_1, A_2 and A_3, each corresponding to a picture area of the standard cinematograph film, and arranged to expose three successive picture areas. The film, B, is moved forward by intermittent mechanism, which is adapted to move the film forward at each shift a distance corresponding to three picture spaces. A suitable objective, C, is placed in front of each aperture, and in front of the objectives a prism, D, is provided comprising

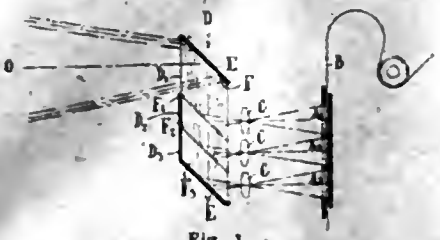

Fig. 1.

three separate prisms, D_1, D_2 and D_3, of rhomboidal section mounted in one frame, E. The separate prisms, D_1, D_2 and D_3, have one pair of their parallel faces coplanar. The rays of light radiating from the object, O, strike against a primary reflecting surface, F, of the prism and are reflected on to secondary reflecting surfaces, F_1, F_2 and F_3, which in turn reflect a certain proportion of the light-rays through the objectives, C, on to the film B. The secondary reflecting surfaces, F_1, F_2 and F_3 are situated at the face of each separate prism, D_1, D_2 and D_3, remote from the primary reflecting surface, F. In this manner three images are produced on the film, B, without lateral parallax.

As the distances the rays travel to each section of the film are not equal, corrections should preferably be made and the linear inequality or longitudinal parallax be compensated. By allowing for the correction of this distortion when designing or calculating the objectives, C, or by the adjustment of the focal length of the objectives, images of the same size are obtained, at the expense of clearness. One of the images may be probably of colour sensations not so accurately focussed while the others important in colour photography are slightly indistinct. It is obvious that owing to the necessity of compensating for longitudinal parallax the objectives, C, will move different distances when focussing, but always in definite relationship to each other. If desired this definite relationship may be maintained by mechanical means. Another form, illustrated in fig. 2, is an apparatus suitable for the simultaneous production of three identical images upon three separate cinematograph films. An optical system is provided of similar construction to that described. The difference is, that the objectives, C, and their corresponding gate frames and gates, A_1, A_2 and A_3, for the three films are arranged in planes parallel to each other, but at different distances from the central axis, G, of the combination prism. This arrangement enables the length of the path of the light-rays from the object to the films to be the same in each case

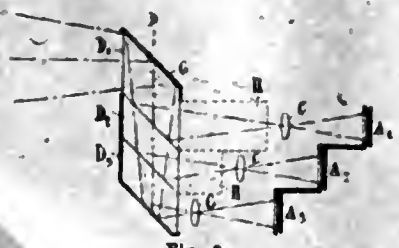

Fig. 2.

and thus eliminate errors due to longitudinal parallax. Another advantage is that objectives, C, of the same focal length may be used to produce identical images. The films are moved forward by intermittent mechanism, which in contradistinction to the previous example, is adapted to move the films at each shift a distance corresponding to one picture space.

As in the first example, the lengths of the paths of the rays in the prisms are different for each image, but in this case and a modification thereof, the degree of distortion is corrected by equalising the lengths of the rays in the substance of the prisms, D_1, D_2 and D_3, and the air in such manner that the length of the medium passed through is the same for the three images. This may be done by placing a correction component. H, between the prisms, D, and D, and the objectives, C, this component, H, preferably comprising a prism of suitable length and of the same material as the reflecting prisms, D_1, D_2 and D_3. In this case all three objectives, C, having the same focal lengths can have the same correction due to prism distortion. In cases, however, where absolute correction is not essential the correction of the objectives, C, for prismatic distortion can be neglected and ordinary photographic lenses may be used.

In a modified form, as illustrated in fig. 3, the prisms, D, may comprise two separate prisms, D_3 and D_4 of rhomboidal section mounted in one frame, J, and having one pair of their parallel faces coplanar. The prism, D_1, bearing the primary reflecting surface F (figs. 1 and 2,) may be eliminated and the prism, D_3, which corresponds to the first of the secondary prisms shown in figs. 1 and 2 may be adapted to permit rays to pass through the first of the series of objectives, C, on to the first film area, K. In addition to this a proportion of the rays from surfaces L and L_1 are reflected through the second of the series of objectives, C, on to the second picture area, K^1, and a second prism, D_4, which reflects by the surface, L_2, the rays through the third of the series of objectives, C, on to the third picture area, K_2. By reason of the surface, L, which corresponds to the primary reflecting surface, F (figs. 1 and 2), permitting rays to pass one of the secondary reflecting surfaces is eliminated, and thus more light reaches the sensitive surface of the films K, K_1, K_2. The regulation of the amount of partial reflection from the secondary reflecting surfaces and the penetrability of a proportion of the rays through the secondary reflecting surfaces may be carried out, by the provision at the reflecting surfaces of a substance having a refraction index differing from that of the glass, or by ruling a metallic or other suitable partial reflecting surface on the secondary reflecting surfaces. Thus a portion of the rays of light may penetrate the mirror, while others are reflected. The total reflecting surfaces of the prisms are, of course, plane

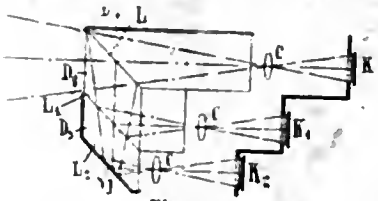

Fig. 3.

mirrors, and may either be silver-plated or simply blackened on their surfaces. When using ordinary photographic objectives the correction of the distortion of the images may be effected either by placing a sphere parallel lens or lenses in front of the system of prisms or in front of each objective so that the images are distorted, the distortion being such that when combined with that due to the system of prisms they will counteract each other. The lens which is referred to as a sphere parallel lens has curved surfaces which, if extended, would form concentric spheres.

Specially designed objectives may be used which correct distortion due to the prisms. In this case the three objectives used are calculated so that their focal lengths are corrected for use with light-rays of a definite wave length, corresponding to those rays passed by the light-filters used. Functions are also introduced for the compensation of chromatic aberration of the rays of the spectral area corresponding to the colour of the light-filters, but the general chromatic aberration of other rays is neglected. The prisms may be attached to each other by means of Canada balsam, which has a refractive index equal to that of the material of the prisms. The partial reflecting surfaces are protected and the light-filters are situated in suitable positions.

COLOUR PHOTOGRAPHY IN SMALL SIZES.

SINCE owing to the present high cost of colour screen-plates there is a tendency to work a smaller size, the 3½ x 2½ size may now be regarded as quite satisfactory. The picture, if cut down slightly, is quite useful for colour slide-making. Colour photography in these smaller sizes demands some precautions, and some notes upon these may perhaps be of service.

The 4½ x 6 cm. or vest-pocket size is almost too small for colour photography, while the saving in cost is not great when compared with the 3½ x 2½ size. Perfectly good work may be done with a vest-pocket Kodak adapted for plates, but there

is a difficulty in handling these in the dark-room. The Autochrome plate, even upon a minimum degree of enlargement, is inclined to show the coloured grains, while the image being small requires greater enlargement than transparencies of larger size. With the short focus large-aperture lenses fitted to these small cameras great depth of definition may be obtained without recourse to a small stop. The colours are also more brilliant when large stops are used.

One disadvantage with a small camera is that the slides may not be deep enough to accommodate the Autochrome plate with its black card backing, while they are useless for the Paget process even when the extra thin taking screens and plates are employed. Those workers who are equipped with the N. & G. double slides will find their equipment suitable in every way. The great danger with these small plates is frilling, which often occurs to a greater degree than is the case with the larger sizes. A defective edge of, say, a quarter of an inch may not greatly matter in those transparencies of quarter-plate size and over, but in the case of a 4½ x 6 cm. or 3½ x 2½ plate this may make a decided inroad upon the picture. Handling the plate with hot fingers is a very prolific source of the trouble. As a preventive I suggest that a metal frame may be constructed, into which the plate could be slipped from one end, the other end being curved upward to serve as a handle. With small transparencies, especially those intended for lantern projection, it is necessary to secure brilliant results. For some notes on this subject I would refer the reader to an article appearing in this "Supplement" for September, 1922.

I assume that most photographers who use the 3½ x 2½ size do so with a view to using their results as lantern slides. In the case of 3½ x 2½ plates it is not a difficult matter to cut a quarter-of-an-inch off one end of the plate, provided the worker is used to cutting glass and is possessed of a good diamond. If this is not the case, a glazier can be persuaded to do the job, but under the worker's personal supervision. A sheet of thick felt, upon which a piece of smooth velvet is laid, should be used for cutting on, the cut, of course, being made from the glass side. Great care is necessary to *break* the film and not to tear it.

To bind up the plate as a lantern slide proceed as follows:—Take a perfectly clean cover glass and lay the transparency film down upon this, exactly central. The edges of the transparency are then given a thin coat of "Seccotine," and the two plates are placed on one side until the adhesive is perfectly dry. The slide is then bound up in the usual manner, a fairly wide binding being used on the short side of the plate. If a 4½ x 6 cm. Autochrome is to be bound up, a slightly different procedure is necessary. The plate is placed in the centre of the cover glass, and the edges are gummed as before. Great care should now be taken that the Seccotine does not run under the edges of the Autochrome plate, as it is liable to attack the colours. When this plate is ready for binding it will be found that there is considerable space around the small Autochrome which requires filling in. This may be done by cutting pieces of cardboard of the necessary thickness and sufficiently wide to reach to the edges of the cover glass. These may be attached to the cover glass by means of Seccotine and strips of binding so affixed, that the junction of the cardboard and Autochrome is concealed. The slide may then be bound up in the usual manner, and will be found to present no difficulty when it is put through the lantern. In the case of small transparencies made by the Paget process, two methods are available. The easier, perhaps, is to make the small transparency upon an ordinary lantern plate, and use a full lantern size viewing screen. These may be bound up together without trouble; no special precautions are necessary. However, it may not be thought economy to use such a large viewing screen for so small a picture, and in the second method a screen of the size of the actual picture is used. This screen should be carefully adjusted into perfect register, and then held to the lantern plate by spring clips. Seccotine is then applied to the edges, and the whole allowed to become perfectly dry. Pieces of cardboard are then cut to the requisite sizes and affixed, as suggested above, for the small Autochrome plate. The slide is then bound up in the usual manner, and is ready for the lantern.

It should always be remembered, when making colour transparencies for lantern projection, that the most brilliant possible results be obtained. This particularly applies to the small sizes on plates we are now considering, as the slightest flatness or extra density will be fatal to good results when the slide is shown upon the screen. To this end the utmost care and cleanliness should be observed in dark-room manipulations, while the exposure of the plate itself must be most accurately estimated. If development, etc., is carried out with the aid of the metal frames suggested, there should be no reason to expect other than a good result as regards these manipulations, but it is quite apparent that unless the exact times necessary for the complete development, reversal, re-exposure, and re-development of the plate, in the case of the Autochrome, are observed, brilliant pictures cannot be expected. A difficulty often experienced in reversing the Autochrome image, and one which controls the ultimate brilliancy of the picture, is the second exposure to light. This, of course, takes place after the potassium permanganate bath has dissolved out the original negative image, and it should be observed that just sufficient light is used, and that of a suitable quality. It may be found that brilliant sunlight will cause reversal, more or less according to the time of exposure to the light. If this does occur, a flat lifeless image will result upon re-development. It should therefore be remembered that a too long exposure to daylight must be avoided, it being much better to use some artificial means of illumination. An exposure of a few seconds' duration to the light of a half-watt bulb of about 100 candle-power proves sufficient, but failing this one inch of magnesium ribbon at 2 ft. distance from the plate will suffice.

R. M. Fanstone.

DESENSITISING IN THE AUTOCHROME PROCESS.

In a paper read before the Photo-Club of Alsace and Lorraine M. Eugène Muller has some hints to give from his experience in the use of desensitising in the Autochrome process. He writes:—

As is well known, the reddish colour of gelatine film obtained by the safranine desensitiser is destroyed by the permanganate reversing bath. On the other hand, this colour is not removed when a reversing bath of acid bichromate is used. Those who have been accustomed to use the bichromate reverser do not seem to take kindly to the permanganate reverser, which they consider less practical. They are thus led to discard the safranine desensitiser and to use the aurantia desensitiser for Autochrome plates. While the yellowish colour produced on an Autochrome plate by aurantia is not destroyed by the acid bichromate bath itself, washing for 2 to 2½ minutes after the reverser is sufficient to remove the yellow colour.

The panchromatic emulsion of the Autochrome plate being only about half the sensitiveness of the Lumière Blue-Label plate, the degree of desensitisation obtained with aurantia is ample for development quite close to a 16-c.p. carbon-filament bulb used behind four thicknesses of yellow Virida paper. With this illumination there is no risk in examining the plate by transmitted light. Holding it 8 or 10 inches from the light, the instant of "extinction" of the image can be seen as readily as by green light.

In practical working, the plate is placed in the desensitising bath in complete darkness, after which the yellow light can be immediately used, if the precaution is taken of using for desensitising an opaque dish (porcelain or xylonite) and covering it with a card or placing it in shadow. The protection of a shadow of a solid screen is sufficient for the transference of the desensitised plate into the developer. Working in this way, the handling of the plate in the dark is reduced to a minimum. The dark-room clock can be placed in the direct light of the lamp, so that it can be used with the greatest ease for timing both the period of desensitising and the factorial development of the plate.

In transferring the plate from the desensitising bath directly into the developer without rinsing, the latter becomes strongly coloured, but this colour does not prevent the solution from being used for the second development, even when exposure of the plate is made to electric light such as a 32- or 50-c.p. lamp. It is, however, advisable to expose the plate to the light for some seconds before applying the coloured developer and to rock the dish vigorously so as to uncover the various parts of the plate to the artificial light, or to daylight if that is used, during re-development.

It will thus be seen that when re-developing desensitised plates it is not necessary to use a stronger illumination than when re-developing plates which have not been desensitised. Apparently this arises from the fact that, as noted by Lüppo Cramer, desensitisation acts only on the surface of the emulsion grain, and that these surface grains are removed by the reversing bath.

Colour Photography.

CONTENTS.

THREE-COLOUR BROMOIL TRANSFER.

To the colour photographer who works those processes demanding three separate negatives each of a separate colour sensation, many different means of printing are available, and he may find much interest in trying the processes that have been suggested from time to time. One of the most interesting that I have tried is undoubtedly that which uses Bromoil methods to produce the resulting image in colour on the bromide print, but even this may be improved upon by working Bromoil transfer. Three-colour prints made by this means, providing careful attention has been given to all the details of the process, are extremely beautiful, and preserve all the delicate colourings of the original subject. The control which this process allows is of great help in the modification of individual colours, and after the worker has made one or two complete prints he will find that he is capable of producing a colour photograph in which careful adjustment of the various inks gives the effect that he desires.

The necessary negatives are made in the usual manner by exposure through blue, green and red filters upon panchromatic plates. In developing these, it must be remembered that they will be required for enlarging, and must consequently be thinner in density than those used for contact work. To obtain equal density, but, of course, varying according to the depth of colour, it is desirable that the three negatives should be developed in one and the same dish at the same time and with a fairly weak developer. I find the "B.J." pyro-soda developer, diluted with an equal volume of water, to be an excellent one which will give negatives of the required density in about 3½ to 4 minutes. The negatives when dry should be carefully marked with the name of the filter through which the exposure was made and also the colour of the resulting image, thus—blue negative yellow print, green negative red print, red negative blue print. This is a safeguard against error in printing, which is often difficult to rectify or even find out until the final print is made.

The making of the three bromide enlargements is the next procedure, and great care should be taken to ensure each print being of equal density and developed to the full extent of the exposure. It is best to use fresh developer for each print: by this, I mean that each print should have an equally strong developer, and not one that has been used previously. The best method is to make up three measures of solution. 4 ozs. is sufficient if whole-plate enlargements are being made—and use one measure for each print. Amidol, 3 grains per ounce, is a very good strength, and with the present makes of Bromoil bromide paper works very well, and gives good, deep prints. The time of development and also the temperature of the solution should be taken when developing the first print, and these conditions kept constant with the other two prints. It is most necessary to attend carefully to these details, since so much depends upon obtaining three prints of equal density and quality. The enlargements should be fixed in a plain hypo solution, 3 ounces hypo to 1 pint water, for ten minutes, and then washed for one hour.

The prints, when dry, are ready for bleaching, but should first of all be squared up and trimmed so that each enlargement is of exactly the same size and the image in the correct position. A good method of obtaining this equality in size and position of picture is to place the three enlargements on top of each other and view them by a strong transmitted light. They may now be exactly superimposed, and when this condition is obtained a pin is pushed through the three prints at each of the four corners of the picture. The prints may now be trimmed to these pinholes and so will be all of exact size, the image being in the same position in each print.

Any good bleacher may be used, providing it is not intended to be used in too hot a solution. However, it should be borne in mind that the temperature of the bleaching bath and wash water should be equally maintained in each instance. It is not necessary to fix after bleaching, the silver image taking no part in the final print. As it is only possible to ink one print at a time, it is therefore necessary to bleach each print as it is wanted, and no trouble will be experienced in this direction if all the prints are dried first. Personally I bleach the print which is to receive the yellow image, first, as I prefer this colour at the bottom of my finished result. The procedure of inking the print differs very little from ordinary Bromoil practice, but one has to bear in mind the strengths of colour in the original subject. The best way to do this is to make a note at the time of exposure, thus predominant yellow or predominant green, etc. I find this helps considerably in the inking, and allows of the increasing or subduing of any colour to suit the subject. The inks may be obtained from any dealer in printing inks, but they should be of the very best quality. The inks supplied for three-colour half-tone printing work very well; these should be ordered as tricolour red, tricolour yellow, and tricolour blue. Roberson's medium may be used for thinning if necessary, but usually the inks will be found quite workable as they are. The print from the blue negative is first inked in yellow pigment; I find it best to do this by daylight, as it is difficult to judge the extent of inking by artificial light.

When the print is fully inked it is ready for transferring. As the final support, any good quality of drawing paper with a fairly smooth surface may be used. This paper is first damped by being placed between wet blotting paper; it is then removed and placed upon a pad of dry blotting paper on a sheet of three ply wood. The yellow print is now laid face down on the transfer paper and a pencil line drawn around its edge upon the transfer. This acts as a guide for the other prints and allows easy registration. Several sheets of clean blotting paper are now placed on top, and over this a piece of printer's blanket, when the whole is ready for the press. An ordinary rubber-roller mangle or wringer works very well, but good pressure is necessary. The print should be passed through three or four times backwards and forwards, taking care that no stoppage occurs during the process.

The bromide is now stripped from the transfer, and it will be found that the latter now holds the ink. The next print to ink in the blue, from the red negative. It is usually found that the blue ink is very intense, and care should be taken that this print is not over-inked. Transferring takes place exactly as in the yellow print, care being taken that the edge of the print corresponds with the marks upon the transfer paper. Finally the red print is inked and transferred upon the other two-colour images, when, if care has been taken during the process, it will be found that the result fully justifies the amount of trouble taken.

H. H. FEATHERSTONE, F.R.P.S.

COLOUR CINEMATOGRAPHY WITH NON-INTERMITTENT FILM.

[Among the inventors who continue to attack the problem of cinematography in natural colours is M. Edouard Belin, well known as a successful experimenter in the telegraphic transmission of photographs. According to a patent specification, No. 157,196, applied for in Germany in 1914, under the International Convention, but only recently accepted in this country, M. Belin has designed a form of cinematograph camera and projector in which the film moves continuously. It is claimed for this pattern of apparatus that it provides the means for three-colour cinematography much more efficiently than apparatus in which the film is exposed, and projected intermittently.]

THE principle of the system will be understood by the following general description :—Assume A (fig. 1) to be a transparent cylindrical surface against which a film P is supported which carries a succession of positive pictures resembling the ordinary cinematograph films, whilst S is a powerful source of light provided with a condenser C and an objective (not shown) forming an illuminated rectangle of the dimensions of an elementary print.

By means of moving prisms p or reflecting mirrors, light from this source of illumination plays upon the film P and is projected on the elementary images in succession at the same time as a diaphragm D is displaced over the other face of the film, the rectangular opening d of which diaphragm had also the dimensions of an elementary print. Finally a rotatable high power objective having a very small field of view is located at O in such a way that the axis of the cylinder A cuts the optical axis at the focal point. This objective forms on a cylindrical surface A^1 the image of the film P and as the elementary positives are illuminated one after the other, the images are also successively formed side by side at A^1 one after the other. If the radius of the cylinder is equal to twice the principal focal length of the objective, the images will have the same size as the positives and the surface A^1 of the same radius as A will be on the same cylinder and symmetrical relative to the objective O.

By interposing in an emergent group of rays, a reflecting surface M, the images which would be normally formed at A^1 may be reflected in any suitably selected direction. Assuming that such a mirror M^1 reflects the picture A^1 to A^{11} the same calculation may be made and a similar construction employed for the second image, which may be called B^{11} (not shown), but instead of bringing B^{11} beside A^{11} it may be made to coincide with the latter. It suffices for this to give the mirror M^2 a slightly different inclination to that of the mirror M^1. If this is continued for each picture, the position necessary for the mirrors may be ascertained. For this, it is only necessary to consider the centre of each image.

In order that all the images may be equally superposed, it is necessary that the sum of the lengths of the incident ray and the reflected ray shall be constant, that is to say, that $OM^2+M^1A^{11}=OA^1$.

O and A^{11} are, however, two fixed points. The centres of the mirrors must therefore lie on an ellipse having the centres of the objective O and of the image A^{11} for foci.

If in such a system, there is placed at A^{11} a white screen or a ground glass, and the objective O is turned continuously towards the positives which are simultaneously uncovered by the diaphragm D and illuminated by the revolving prism p, an observer sees a single image continuously illuminated and strictly stationary, because in proportion as the diaphragm uncovers one of the elementary positives it conceals a corresponding part of the precedent print or picture. If the photographs placed at A have been taken one after the other, and if the subject comprises at this moment movable objects, such for example as persons in movement, the observer notices at A^{11} that the stationary objects retain this property under projection and that objects which are moving appear as in real life.

Consider a suitable illuminated object V (fig. 1),

If this object be observed through a convenient lens of large aperture or a divergent lens, the eye perceives between the object and

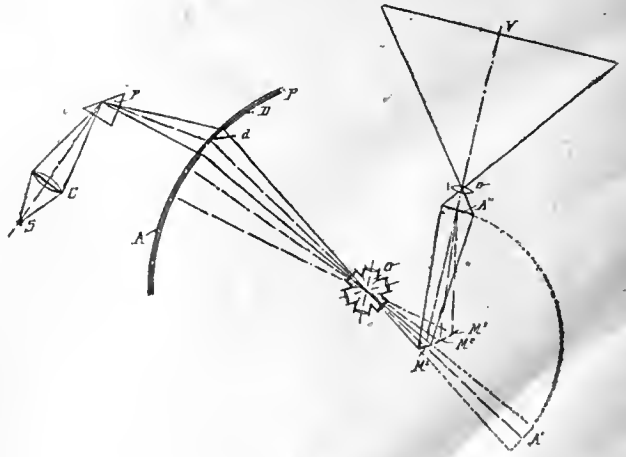

Fig. 1.

the lens and apparently on the lens, an actual clear image at the distance of distinct vision and for any superior distance.

It is this image which the objective of the apparatus must photograph after reflection of the rays by the series of mirrors placed on the elliptical surface.

The apparatus is thus composed of a suitable optical arrangement O adapted to give an image which is virtually erect or reversed to the object photographed.

A series of mirrors M placed in an ellipse and suitably regulated, repeats this image in as many juxtaposed images owing to the interposition of an objective O placed at one of the foci of the ellipse, the centre of the image occupying the other focus.

In the focal plane and along a cylinder A a sensitive film P is placed before which a rectangular diaphragm D having the dimensions of an elementary image is displaced.

At the commencement of the operation, the diaphragm being at one of the ends of the cylindrical surface A occupied by the film and the objective O being directed towards this same place, a first image is quite clearly printed.

After the portion of the cylinder, the length of the arc of which is equal to the product of the length of a print by the number of the mirrors, has been explored by the objective, a suitable arrangement replaces this portion of the film by another, the diaphragm and the objective return to their point of departure and everything recommences.

In order to avoid interruption, however short it may be, which would be necessary for this returning to their original positions of the diaphragm and the mirrors, a diaphragm in the form of an endless film or band may be assumed on the one hand carrying equidistant openings which form apertures, and on the other hand a multiple objective formed of several tubes regularly and symmetrically arranged about a common axis of rotation. In this case, for example, with an angle of exploration of 60 deg., the objective would be formed of 6 tubes constituting between them angles of 60 deg. and each carrying one of the two lenses of a similar symmetrical system.

The reproducing or projecting apparatus embodies the general principles explained, and is composed of :—

(1) A powerful source of light S;
(2) A revolving reflecting arrangement as prisms or mirrors *p*;
(3) A cylindrical surface A of glass of an arc of about 60 deg.;
(4) A revolving objective O having several symmetrical tubes.
(5) A series of mirrors placed on an elliptical surface M.
(6) A second, short, focus, objective o.

The positive film P formed by the series of pictures to be projected bears against the cylindrical glass surface A.

An endless, thoroughly opaque, band D perforated merely from place to place at suitable regular distances with a rectangular

Fig. 2.

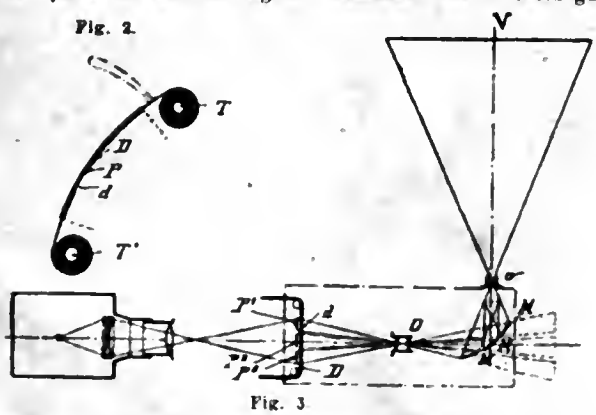

Fig. 3

opening *d* of the exact dimensions of an elementary print or picture may be displaced in front of this film.

The revolving optical reflecting arrangement *p*, the diaphragm D and the objective O are connected with the same mechanical control ensuring their movements being perfectly simultaneous.

Finally, quite as in the recorder, a suitable mechanical arrangement expels the film which has just been projected by drawing into its place the one which is to be projected a little later and by this movement gradually the length of film corresponding to that of the arm is completely renewed when the diaphragm having explored the last print or picture, the succeeding window commences the exploration of a fresh series of pictures.

In fig. 2 there is shown, for example, the film P stretched between two reels T T' and in front of and against it the diaphragm D is displaced. During this displacement the drum or reel T revolves, the film unwinds, forming a loop, the length of which is that of the arc when the window of the diaphragm has finished its course. At this moment the diaphragm brings up another window and suddenly the reel T' winds up the film, drawing the loop taut in front of the diaphragm in place of the arc which has just disappeared.

If, for example, the length of the arc is 60 centimetres, and each print of the picture has a base of 2 centimetres, the time of exploration by the window, for the rate of 15 prints or pictures per second, will be exactly two seconds.

During this relatively long time the foregoing mechanical action is very easily realisable.

As in the arrangement of fig. 1, the image V (fig. 3) furnished by an objective of large diameter or a divergent lens is photographed by a second objective O after reflection of the rays by three mirrors M or three prisms in such a way that three identical real images are formed normally and simultaneously in the focal plane where the sensitive surface P is found. The second objective O is, however, selected with a sufficiently long focus and with sufficient correction that the three elementary prints which are juxtaposed are formed on one plane surface (the number 3 may be any suitable number).

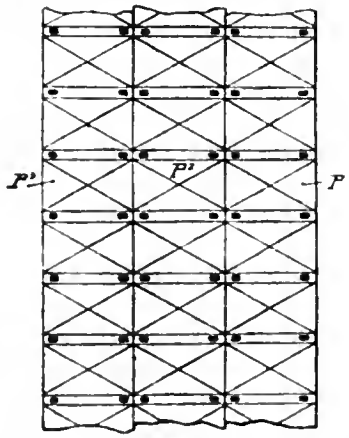

Fig. 4.

The whole is regulated so that the three elementary images are exactly juxtaposed without an interval reserved for any other object, such as that of perforations for moving them on. The correctness of this juxtaposition is indispensable to the absolute theoretical functioning of the apparatus.

If it be assumed that the elementary images are, as in the ordinary cinematograph, 35 mm. at the base by 20 mm. in height, the three images will be juxtaposed by the small side of the rectangle and their whole will thus form a horizontal rectangle of $35 \times 3 = 105$ mm. at the base by 20 mm. in height.

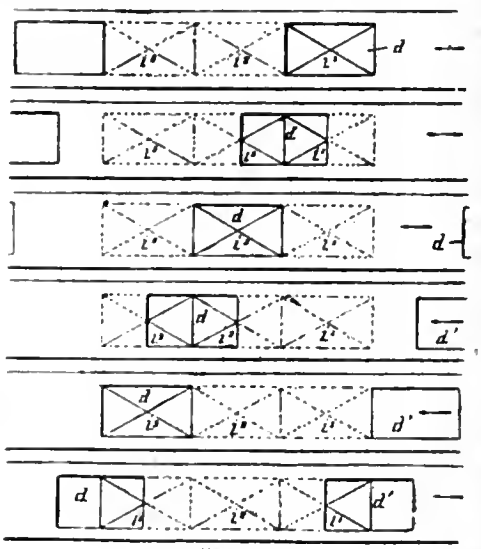

Fig. 5.

Here the ordinary objective O, formed of a single tube, remains immovable, and the number of the mirrors or prisms is reduced to three.

But instead of a single film there are three films, P^1, P^2, P^3, which are juxtaposed parallel and directed so that their axes coincide with the small axis of each image (fig. 4).

The width of each film is exactly equal to the base of a single elementary image, say, for example, 35 mm., the movement by means of points, cams or helices, or by any other suitable arrangement is no longer produced by means of holes formed in the white

margin reserved on the sides of the film. These holes are in an interval reserved between each elementary print or picture on the same band.

An endless, flexible and opaque curtain D, perforated with equidistant windows, is displaced in a continuous manner before these three films, and following a direction parallel with the base of the images. Each window is of exactly the dimensions of an elementary image and the interval between two successive windows d, d^1 is equal to twice the larger base of these same imagee (fig. 5).

When the operation commences it is assumed that the window d will totally illuminate the first elementary print or picture, whilst the two identical images i^2, i^3 are formed on the opaque part of the endless shutter. The first film P^1 is then printed without there being any action on the other two P^2 P^3, but at this moment the shutter band D is being displaced and the second elementary image is printed on P^2, whilst successively the parts corresponding to P^1 are covered. When the second image i^2 is entirely exposed, the first film P^1 is no longer concerned, and it is then that its displacement is produced. This displacement in order to be produced has all the time taken by the window for reaching the extreme edge of the third film P^3.

It is then the turn of the second film P^2 to be displaced whilst the curtain commencing to mask P^3, the second window d^1 commences to illuminate P^1 in its fresh position. On this film P^1 a second print, the fourth of the series, is printed above the first i^1, and when it is fully exposed P^3, which is completely eclipsed, commences its displacement, and so forth up to the end of the operation. The diagrammatic description just given of the apparatus for taking views enables the projecting apparatus (fig. 3) to be immediately understood.

Here, there are, of course, three prisms or mirrors M, the objective O placed between these latter and the diapositivea P and finally the curtain D with windows d placed in front of the three films P^1, P^2, P^3, which are shown and moved according to the same rules as for taking the views.

The objective with wide aperture or the divergent lens are here alone replaced by the short focus projecting objective o.

For cinematography in colours, the statements above, as a whole, may be repeated as regards the theoretical arrangement. However, for taking views, or their projection, the apparatus is presented in the following way :—

Nine elementary prints or pictures are simultaneously exposed because each of the three films is printed at the same time with three identical pictures placed vertically one above the other opposite the large sides of the rectangles. But, for this, intimate juxtaposition is no longer necessary, and between each print there continues to be reserved the indispensable perforated spaces for moving the film as in fig. 4. Before each image of this vertical series one of three coloured filters is placed. This causes, by reason of the three parallel films, the rectangle formed of nine images to be seen through three horizontal glass bands, constituting in one case one of the ternary colours, and in the other cases the other ternary colours.

The window has a treble height. If, for example, the images are 35×20 and the reserve and perforated spaces 35×3;

A. The bands of coloured glass are 105×20 mm ;

B. The window is $35 \times (20+3+20+3+20)$ or 35×66 mm.

The inverse reasoning is applicable to the apparatus for taking polychrome views.

To all the technical advantages which characterise this improved cinematograph process as a whole, there must be added others of a material nature.

First of all, by reason of the continuity of the view, there is no necessity imposed of multiplying beyond measure the number of elementary pictures, and from this fact there must result a considerable saving in the consumption of films.

On the other hand, the substitution of a space reserved between two images for the two margins habitually employed also constitutes a saving, less evident than the foregoing, but nevertheless appreciable, if the length of the films at present employed in cinematography be considered.

Practical Color Photography. — Our publishers, Messrs. Henry Greenwood and Co., Ltd., who are supplying the new manual, "Practical Color Photography," by Mr. E. J. Wall, inform us that following the rapid exhaustion of the first delivery from the American publishers, they have now received a second consignment, and are able to supply the book post free to any part of the world at the price of 13s. 3d.

AUTOCHROMES AND SUN SPOTS.

Among writers in France on Autochrome work reference has been somewhat frequently made of late to the tendency of the Autochrome plate to give results, the colour rendering of which is somewhat on the bluish side. Several workers have made suggestions of means by which this effect may be prevented, such as the use of different compensating light-filters, but no one hitherto appears to have suggested the cause of the phenomenon except by the assumption that either the mosaic filter or the emulsion is not the same as that previously manufactured by MM. Lumière. The latter, however, have been able to give their very positive assurance that the product remains identical with that issued as long ago as in the years before the war, since the materials are taken from precisely the same stock.

A remarkable suggestion respecting the cause has recently been put forward, namely that it is a variation in the spectral composition of solar light, due to the occurrence of spots on the sun. This theory is ventilated in an article in a recent issue of "Photo-Revue," where M. J. Lacroix discusses it, and receives the support of M. L'Abbé Moreux, superintendent of Bourges Observatory. M. Lacroix writes :—My experience confirms that of many other amateurs. After having closely noticed that for a considerable time my results tended towards a bluish tone, I made numerous comparisons, not simply on single plates but with series of exposures, and communicated the results to MM. Lumière. I learnt that the manufacture remained identically the same; the same emulsions and the same dyes, taken from existing stock. After a certain lapse of time I repeated my tests, but with the same results, and was thus led to the belief that some unknown cause required to be found to account for the difference. Although the suggestion may arouse ridicule, I will state it nevertheless. May it not be that the sun itself is responsible for the difference in the colour rendering. At a conference held at Agen three or four years ago M. L'Abbé Moreux, in the course of a lecture on various astronomical subjects, referred to sun spots. It appeared to me that, in addition to the many great results which coincide with the occurrence of spots on the sun, a difference in the results on Autochrome plates may be included, and on putting this question specifically to M. Moreux, he replied that it was quite possible that there was a difference in the solar radiation requiring a modification of the colour sensitiveness of the plates or an alteration in the compensating light-filters. MM. Lumière, in their turn, expressed the view that if such modification had shown itself to be necessary they would have had experience of it in the course of their tests, but, on the other hand, it is possible that MM. Lumière's tests are not made under such various conditions of light, subject, time of year, etc., as are those undertaken by the ordinary users of the plates. In some circumstances the tendency to blueness is scarcely appreciable and even entirely absent. In photographing subjects which are fairly close to the camera and are taken in a bright light, at about midday, the results are excellent when correctly exposed and developed. But in the early morning, or late evening, when the light is rich in colour, subjects which include great distances exhibit, as regards these portions, a very marked blueness. I can only suppose that MM. Lumière have not made tests with this particular kind of subject and, therefore, have not experienced the necessity for some modification of the process. Nevertheless, my own experience with subjects in which the light reaches the camera through large areas of the atmosphere leads me to believe that same modification of the compensating filters or the colour-sensitiveness of the emulsion has become necessary. I am very far from wishing to dogmatise in this matter, and have written solely for the purpose of eliciting the experience and enlisting the collaboration of all those who have derived such great pleasure from the marvellous results with the Autochrome process.

Three-Colour Transparencies.—In reference to the paper by Mr. Frederic G. Tutton, which appeared in the "Colour Photography" Supplement for November 3 last, Mr. Tutton writes to inform us that in common with the "Club Photographer" a misstatement was made respecting the exhibit of his to which a medal was awarded at the recent exhibition of the Royal Photographic Society. The transparency which secured the award at the R.P.S. was not made by the process described last month, but by three-colour carbon with subsequent intensification of the colours as described in the catalogue.
